

# BASELINE AND POTENTIAL STUDY REPORT ADDENDUM

**TO** ComEd, Ameren Illinois, and Nicor Gas  
**CC** Illinois Commerce Commission, Illinois Attorney General Office, National Resources Defense Council, and National Consumer Law Center  
**FROM** GDS Associates  
**DATE** January 06, 2025  
**RE** Baseline and Potential Study Report Addendum

## INTRODUCTION

During the drafting of the final report for the Illinois Baseline and Potential Study, GDS received comments and requests that could not cleanly be accommodated in the body of the report without delaying the delivery of the final product. These addenda address those comments and requests fielded by the GDS team. Most address requests for additional detail related to details underpinning the potential study results, with one that expands on detail related to the residential baseline study. These addenda serve to provide additional results breakouts that were either not included in the main report and/or were not easily viewed in the detailed results files provided to the Joint Utilities and Potential Study Working Group stakeholders.

## REQUEST FOR ADDITIONAL INFORMATION AND RESPONSES: UTILITY LEVEL RESULTS

**REQUEST #1:** For Figures 5-4 and 5-9 (and 6-4 and 6-9), please provide the figures the include a breakdown of electrification and traditional energy efficiency.

**RESPONSE#1:** The figures listed in the request above provide the Maximum Achievable Potential (MAP) and Realistic Achievable Potential (RAP) incremental annual savings from 2026-2029 by sector and electric utility. The tables below provide the requested details to show the incremental annual savings that include a breakdown of net electrification savings and traditional energy efficiency for MAP and RAP.

Figure 5-4 detail (ComEd – Residential)

|                        | 2026    | 2027    | 2028    | 2029    |
|------------------------|---------|---------|---------|---------|
| <b>MAP</b>             |         |         |         |         |
| Res. Market Rate EE    | 409,618 | 411,378 | 405,360 | 395,716 |

**REQUEST #2:** For Table 5-2 and 5-3 (and 6-2 and 6-3), consider providing an explanation of how you convert net Btus to electric, and breakdown of the actual added electric impacts (kwh) versus the reduced gas (therm) impacts.

**RESPONSE#2:** Table 5-2, 5-3, 6-2 and 6-3 provide a breakdown by sector and electric utility of the RAP savings between traditional EE and Electrification. The electrification impacts are net electric impacts and include the added kWh as well as the reduced therm savings (converted to electric savings). The therm savings are converted to kWh savings by a formula:  $\text{therms} * 100,000/3413$ .

Table 5-2 detail (ComEd – Residential)

|                          | 2026        | 2027         | 2028         | 2029         |
|--------------------------|-------------|--------------|--------------|--------------|
| Added kWh                | -76,491,415 | -114,737,968 | -127,451,360 | -136,533,523 |
| Reduced therms           | 15,330,856  | 22,996,417   | 25,545,987   | 27,367,293   |
| Net Electric Saved (MWh) | 372,699     | 559,051      | 621,039      | 665,321      |

Table 5-3 detail (ComEd – C&I)

|                          | 2026        | 2027        | 2028        | 2029        |
|--------------------------|-------------|-------------|-------------|-------------|
| Added kWh                | -53,559,027 | -80,338,541 | -89,265,045 | -95,641,120 |
| Reduced therms           | 9,787,803   | 14,681,705  | 16,313,005  | 17,478,220  |
| Net Electric Saved (MWh) | 233,221     | 349,832     | 388,702     | 416,466     |

Table 6-2 detail (Ameren Electric – Residential)

| Net Electric Saved (MWh) | 98,791      | 148,187     | 164,652     | 176,413     |

Table 6-3 detail (Ameren Electric – C&I)

|                          | 2026        | 2027        | 2028        | 2029        |
|--------------------------|-------------|-------------|-------------|-------------|
| Added kWh                | -16,869,773 | -25,304,660 | -28,116,289 | -30,124,595 |
| Reduced therms           | 3,406,773   | 5,110,160   | 5,677,956   | 6,083,524   |
| Net Electric Saved (MWh) | 82,948      | 124,422     | 138,246     | 148,121     |

**REQUEST #3:** For all end-use pie charts (i.e. Figure 5-5), please provide a figure that shows the breakdown of savings by end-use over time.

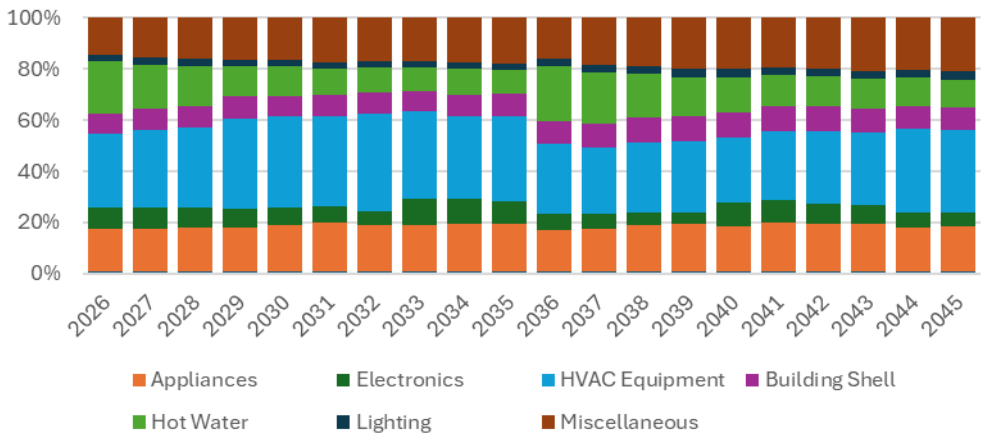

**RESPONSE#3:** The end-use pie charts provided in the main report are based on the 20-year cumulative (2045) annual RAP. The figures provide the cumulative annual potential by year. The figures are by utility and sector.

Breakdown of ComEd Cumulative Annual RAP by Year - C&I

Breakdown of Ameren-Electric Incremental Annual RAP by Year - Residential

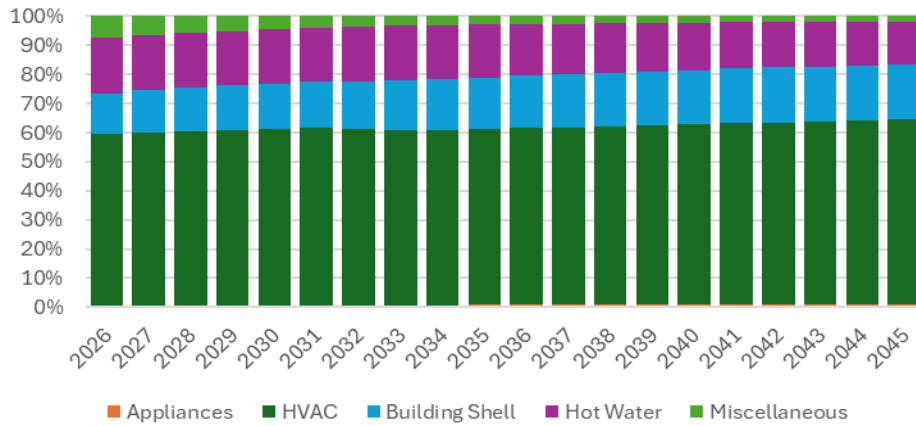

Breakdown of Ameren-Electric Cumulative Annual RAP by Year - Residential

Breakdown of Nicor Gas Incremental Annual RAP by Year - Residential

Breakdown of Nicor Gas Cumulative Annual RAP by Year - Residential

Breakdown of Nicor Gas Cumulative Annual RAP by Year - Residential

Breakdown of Ameren Gas Cumulative Annual RAP by Year - Residential

**REQUEST #4:** Please comment on the future savings opportunities from emerging technologies (i.e., Figure 5-7 and 5-12 in the ComEd chapter) and provide additional clarity on the types of measures that make up these future opportunities.

**RESPONSE#4:** The table below provides the end-use of the emerging technologies identified in the 20-year cumulative annual RAP.

|  | ComEd      | Ameren-E   | Nicor Gas  | Ameren-G   |
|--|------------|------------|------------|------------|
| <b>Residential</b>                     |            |            |            |            |
| Appliances                             | 3%         | 4%         | 0%         | 0%         |

| Miscellaneous                          | 1%         | 1%         | 0%         | 0%         |
| <i>Total ET (as a % of sector RAP)</i> | <i>8%</i>  | <i>7%</i>  | <i>10%</i> | <i>8%</i>  |

Residential electric emerging technologies savings in the building shell are represented by advanced insulation and windows, and by advanced heat pumps, air conditioning, and duct sealing in the HVAC equipment end-use. Additional residential electric emerging technology savings are represented by advanced home energy management systems (miscellaneous), advanced lighting controls (lighting), advanced heat

pump water heaters (hot water), and ultrasonic clothes dryers (appliances). For residential gas, emerging technologies savings were derived from advanced duct sealing and natural gas heat pumps (HVAC), advanced insulation and advanced windows (shell), advanced home energy management systems (miscellaneous), and advanced future natural gas water heating (hot water).

In the C&I sector, electric emerging technology savings were led by HVAC equipment (adsorbent air filtration, advanced duct sealing, Advanced EMS, and future ventilation and circulation improvements), lighting (future lighting improvements), future process improvements, future compressed air, and miscellaneous (advanced laundry). C&I gas emerging technologies include condensing gas rooftops and natural gas heat pumps.

Near and mid-term emerging technology savings made up 95% or more of the residential electric and gas emerging technology savings, with future “innovative” technologies representing 5% or less of the 20-yr cumulative annual potential. In the C&I sector, near and mid-term emerging technology savings represented roughly 55% of the 20-year cumulative annual potential for electric, and 100% for natural gas.

**REQUEST #5:** Please comment on the overall RAP public sector savings relative to sales.

**RESPONSE#5:** The table below provides the estimated public sector savings as a percent of total C&I RAP potential, as well as public sector sales (as a percent of total eligible C&I sector sales).

|   | ComEd | Ameren-E | Nicor Gas | Ameren-G |
|---|-------|----------|-----------|----------|
| Public Sector- % of C&I RAP             | 12%   | 7%       | 7%        | 11%      |
| Public Sector- Estimated % of C&I Sales | 11%   | 11%      | 8%        | 9%       |

**REQUEST #6:** Regarding Table 5-6, a stakeholder noted that electrification savings potential is higher in the STIP scenario was higher than the SMAP scenario and requested clarification on why that occurs.

**RESPONSE#6:** As noted in Section 2.5.4.2.1, In discussion with the Joint Utilities and other Parties, electrification spending was capped at 20% of the income-eligible spending target, to allocate at least 80% of income-eligible funding towards traditional energy efficiency programs and measures. In turn, the income-eligible electrification spending cap (and associated savings) would dictate the required level of savings from market rate & nonresidential electrification (i.e., combined, no more than the 75% of electrification savings).

With higher income-eligible spending in the STIP scenario, there was a higher level of income-eligible electrification spending resulting in higher income-eligible electrification savings. As the income-eligible electrification savings increased, it also increased the allowable savings from the residential market rate and nonresidential sectors.

**REQUEST #7:** Regarding Table 5-7, a stakeholder noted that similar levels of overall savings between the SMAP scenario and STIP scenario, and requested additional context given the lower budgets available for non-income eligible opportunities.

**RESPONSE#7:** While the SMAP and STIP scenarios have identical total budgets, the STIP scenario has increased spending on the income-eligible sector. Another key difference, noted in Section 2.5.4.2.3 is that the STIP scenario reserved 80% of the sector spend targets for measures that are currently offered in existing utility portfolios. Only 20% of the spending target was permitted for measures that were designated as “not currently offered.” This helped to ensure that the STIP savings levels were derived primarily from measures that are currently offered by utilities versus potentially more costly “no program” measures.

Thus, while there was more spending on the income-eligible sector in STIP scenario, and the income-eligible sector may have higher acquisition costs for saved energy, it was counter-balanced by focusing residential market rate and nonresidential spending on current program measures that have typically less expensive acquisition costs (relative to not currently offered measures), whereas the SMAP scenario did not prioritize current program vs. not currently offered measures.

**REQUEST #8:** Please provide a breakout of the acquisition cost table across key sector/measure groups.

**RESPONSE#8:** The acquisition cost table is the last table in each utility level results chapter. It provided a comparison of the acquisition costs from 2026-2029 for each of the scenarios. For ComEd, the table includes acquisition costs with and without the impacts of any converted gas savings. As noted in the report, GDS did not include converted gas savings for Ameren due to their status as an electric and gas utility. GDS has provided additional details of acquisition costs by sector (residential, income-eligible, and commercial) by utility, below.

Table 5-11 (Converted Gas Included) detail (ComEd - \$/MWh)::

|                                | 2026  | 2027  | 2028  | 2029  |
|--------------------------------|-------|-------|-------|-------|
| <b>Residential Market Rate</b> |       |       |       |       |

**REQUEST #9:** Please provide the overall benefit, costs, and benefit-cost ratios associated with the scenario savings. If possible, please provide the GHG impacts and an estimate of customer bill savings.

**RESPONSE#9:** The portfolio level annual NPV benefits, costs, and TRC ratios for 2026-2029, by utility and scenario, are provided in the tables below. GDS did not directly separate GHG benefit and cost impacts, nor did it conduct an estimate of customer bill savings.

**REQUEST FOR ADDITIONAL INFORMATION AND RESPONSES: BASELINE STUDY REQUESTS**

**REQUEST #10:** Please provide additional information from the residential onsite results regarding the age and efficiency of furnaces.

**RESPONSE#10:** GDS received a request for an analysis of residential onsite results for the age and efficiency of furnaces. The onsite dataset provides results for a subset of furnaces with manufacturing year. In discussion with the requesting stakeholder, GDS developed the following analysis to summarize the combination of furnace manufacturing year and whether a furnace AFUE indicated condensing (implying higher efficiency) or non-condensing (implying lower efficiency). The manufacturing year is a proxy for the installation year. Due to the relatively small count of furnaces with confirmed manufacturing dates, GDS suggests some caution at interpreting the individual year results. Additionally, due to the count of cases, GDS has not disaggregated single family and multifamily furnaces.

Comparing Furnace Manufacturing Date and Efficiency Shares

| Manuf. Year  | <90 AFUE  | Furnace AFUE<br>90+ AFUE | Share 90+ AFUE |
|--------------|-----------|--------------------------|----------------|
| <2010        | 14        | 7                        | 33%            |
| 2010-2015    | 7         | 11                       | 61%            |
| 2016+        | 24        | 28                       | 54%            |
| 2018+        | 20        | 20                       | 50%            |
| <b>Total</b> | <b>45</b> | <b>46</b>                | <b>51%</b>     |

Overall, approximately half the furnaces in the onsite sample with confirmed manufacturing dates are condensing furnaces (AFUE 90 percent or higher). Data regarding the possible participation of these respondents in efficiency programs is not available. One can presume that program participants will reflect a furnace AFUE 90 percent or greater, though program eligibility may have changed over time. For furnaces manufactured in 2016 or later, the share of condensing furnaces is somewhat higher than the overall sample average (54 percent). However, the limited count of respondents for the whole sample or for more granular timeframes suggests caution at making statistical comparisons.
