2026 Illinois Statewide Technical Reference Manual for Energy Efficiency

Version 14.0

Volume 1: Overview and User Guide

FINAL

September 19, 2025

Effective:

January 1, 2026

Table of Contents

VOLUME 1: OVERVIEW AND USER GUIDE

1 Purpose of the TRM.....5

1.1 Acknowledgments.....5

1.2 Summary of Measure Revisions.....8

1.3 Enabling ICC Policy.....21

1.4 Development Process.....21

1.4.1 Reliability Review.....23

2 Organizational Structure.....25

2.1 Measure Code Specification.....25

2.2 Components of TRM Measure Characterizations.....26

2.3 Variable Input Tables.....27

2.3.1 C&I Custom Value Use in Measure Implementation.....28

2.4 Program Delivery & Baseline Definitions.....28

2.4.1 Default Measure Type for Program Delivery Methods.....30

3 Assumptions.....32

3.1 Footnotes & Documentation of Sources.....32

3.2 General Savings Assumptions.....32

3.3 Shifting Baseline Assumptions.....32

3.3.1 Linear Fixture Baseline Assumptions.....33

3.3.2 Early Replacement Baseline Assumptions.....33

3.3.3 Furnace Baseline.....33

3.4 Carryover Savings / Deferred Installs.....34

3.5 Provisional Measures Savings Assumptions.....34

3.6 Glossary.....35

3.7 Electrical Loadshapes (kWh).....40

3.8 Summer Peak Period Definition (kW).....46

3.9 Heating and Cooling Degree-Day Data.....46

3.10 Measure Incremental Cost Definition.....51

3.11 Discount Rates, Inflation Rates, and O&M Costs.....52

3.12 Interactive Effects.....54

3.13 Electrification and Fossil Fuel Baselines (Public Act 102-0662).....54

3.13.1 Fossil Fuel Baseline Efficiencies for Electric Efficiency Measures.....54

3.13.2 Fuel Units and Conversion Factors.....56

3.14 Secondary kWh Savings from Fossil Fuel Saving Measures.....57

1 Purpose of the TRM

The purpose of the Illinois Statewide Technical Reference Manual (TRM or IL-TRM) is to provide a transparent and consistent basis for calculating energy (electric kilowatt-hours (kWh) and natural gas therms) and capacity (electric kilowatts (kW)) savings generated by the State of Illinois' energy efficiency programs,[1] which are administered by the state's largest electric and gas Utilities (collectively, Program Administrators or the Utilities).[2]

The TRM is a technical document that is filed with the Illinois Commerce Commission (Commission or ICC) and is intended to fulfill a series of objectives, including:

- "Serve as a common reference document for all… stakeholders, [Program Administrators], and the Commission, so as to provide transparency to all parties regarding savings assumptions and calculations and the underlying sources of those assumptions and calculations.
- Support the calculation of the Illinois Total Resource Cost test ("TRC"),[3] as well as other cost-benefit tests in support of program design, evaluation, and regulatory compliance. Actual cost-benefit calculations and the calculation of avoided costs will not be part of this TRM.
- Identify gaps in robust, primary data for Illinois, that can be addressed via evaluation efforts and/or other targeted end-use studies.
- [Provide] a process for periodically updating and maintaining records, and preserve a clear record of what deemed parameters are/were in effect at what times to facilitate evaluation and data accuracy reviews.
- …[S]upport coincident peak capacity (for electric) savings estimates and calculations for electric utilities in a manner consistent with the methodologies employed by the utility's Regional Transmission Organization ("RTO"), as well as those necessary for statewide Illinois tracking of coincident peak capacity impacts."[4]

1.1 Acknowledgments

This document was created through collaboration among the members of the Illinois Energy Efficiency Stakeholder Advisory Group (SAG). The SAG is an open forum where interested parties may participate in the evolution of Illinois' energy efficiency programs. Parties wishing to participate in the SAG process may do so by visiting http://www.ilsag.info/questions.html and contacting the Independent Facilitator, Celia Johnson, at celia@celiajohnsonconsulting.com. Parties wishing to participate in the Technical Advisory Committee (TAC), a subcommittee of the SAG, may do so by contacting the TRM Administrator at iltrmadministrator@veic.org.

1.2 Summary of Measure Revisions

The following tables summarize the evolution of measures that are new, revised or errata. This version of the TRM contains 153 measure-level changes as described in the following table.

Table 1.2: Summary of Measure Level Changes

Change Type	# Changes
Errata	7
Revision	133
New Measure	11
Retired	2
Total Changes	153

The 'Change Type' column indicates what kind of change each measure has gone through. Specifically, when a measure error was identified and the TAC process resulted in a consensus, the measure is identified here as an 'Errata'. In these instances, the measure code indicates that a new version of the measure has been published, and that the effective date of the measure dates back to January 1, 2025. Measures that are identified as 'Revised' were included in the twelfth edition of the TRM and have been updated for this edition of the TRM. Both 'Revised' and 'New Measure(s)' have an effective date of January 1, 2026.

The following table provides an overview of the 153 measure-level changes included in this version of the TRM.

Table 1.3: Summary of Measure Revisions

Volume	End Use	Measure Name	Measure Code	Change Type	Explanation	Impact on Savings
Volume 1: Overview	N/A	3.11 Discount Rates, Inflation Rates, and O&M Costs	N/A	Revision	Update to the current TRM discount rates.	N/A
Volume 2: Commercial and Industrial Measures	Agricultural	4.1.1 Engine Block Timer for Agricultural Equipment	CI-AGE-EBLT-V04-260101	Revision	Measure cost update.	No change
		4.1.11 Commercial LED Grow Lights	CI-AGE-GROW-V08-260101	Revision	Updated DLC Horticultural Specifications to v4.0. Measure cost update. Greenhouse hours added. Nomenclature updated.	No change
		4.1.19 ENERGY STAR Dairy Water Heater	CI-AGE-ESWH-V05-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
		4.1.21 Indoor Agriculture Dehumidifier	CI-AGE-DEHU-V01-260101	New	New measure	N/A
	Kitchen Equipment	4.2.1 Combination Oven	CI-FSE-CBOV-V07-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
		4.2.2 Commercial Solid and Glass Door Refrigerators & Freezers	CI-FSE-CSDO-V04-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
		4.2.3 Commercial Steam Cooker	CI-FSE-STMC-V10-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
		4.2.5 ENERGY STAR Convection Oven	CI-FSE-ESCV-V07-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
		4.2.6 ENERGY STAR Dishwasher	CI-FSE-ESDW-V09-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to measure cost, ENERGY STAR calculator inputs and resulting savings	Dependent on inputs
		4.2.7 ENERGY STAR Fryer	CI-FSE-ESFR-V07-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
		4.2.8 ENERGY STAR Griddle	CI-FSE-ESGR-V08-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to dual fuel system calculations.	Dependent on inputs
		4.2.9 ENERGY STAR Hot Food Holding Cabinets	CI-FSE-ESHH-V06-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
		4.2.10 Ice Maker	CI-FSE-ESIM-V08-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
		4.2.11 High Efficiency Pre-Rinse Spray Valve	CI-FSE-SPRY-V09-260101	Revision	Updated measure cost.	No change
		4.2.21 On-Demand Package Sealers	CI-FSE-ODPS-V02-260101	Revision	Updated measure cost.	No change
		4.2.22 Automatic Conveyor Broiler	CI-FSE-ACBL-V04-260101	Revision	Updated measure cost.	No change
		4.2.25 Efficient Cooktops	CI-FSE-INDC-V02-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
	Hot Water	4.3.1 Water Heater	CI-HWE-STWH-V12-260101	Revision	Updates to default heating and cooling efficiency assumptions based upon GDS Baseline Study data, including 95% distribution efficiency.	Dependent on inputs

Volume	End Use	Measure Name	Measure Code	Change Type	Explanation	Impact on Savings
		4.3.2 Low flow Faucet Aerators	CI-HWE-LFFA-V13-260101	Revision	Update to %Electric v %Fossil DHW.	No change
		4.3.3 Low Flow Showerheads	CI-HWE-LFSH-V10-260101	Revision	Update to %Electric v %Fossil DHW.	No change
		4.3.8 Controls for Central Domestic Hot Water	CI-HWE-CDHW-V08-260101	Revision	Update to %Electric v %Fossil DHW.	No change
	HVAC	4.4.7 ENERGY STAR and CEE Tier 2 Room Air Conditioner	CI-HVC-ESRA-V05-260101	Revision	Addition of language on possible ENERGY STAR retirement.	No change
		4.4.9 Air and Water Source Heat Pump Systems (Centrally Ducted and Ductless)	CI-HVC-HPSY-V13-250101	Errata	Fix of error in ASHPSiteHeatingImpact algorithm for non-fuel switch measures >60kBtuh. Edits to unit conversions when using COP efficiency ratings.	Dependent on inputs
			CI-HVC-HPSY-V14-260101	Revision	Updated measure costs for residential sized units and avoided replacement costs based on new inflation rate	No change
		4.4.11 High Efficiency Furnace	CI-HVC-FRNC-V15-260101	Revision	Updated measure costs for residential sized units and avoided replacement costs based on new inflation rate	No change
		4.4.13 Package Terminal Air Conditioner (PTAC) and Package Terminal Heat Pump (PTHP)	CI-HVC-PTAC-V14-260101	Revision	Update to loadshape and coincidence factors. Update to avoided replacement costs based on new inflation rate. Update to EERexist value	Dependent on inputs
		4.4.14 Pipe Insulation	CI-HVC-PINS-V10-260101	Revision	Update to default heating efficiencies	Dependent on inputs
		4.4.15 Single-Package and Split System Unitary Air Conditioners	CI-HVC-SPUA-V12-250101	Errata	Corrected SEER2 value and compliance date from Code of Federal Regulations for split systems <65,000 Btu/h. Transitioning the SEER/EER metrics for systems <65,000 Btu/h to SEER2/EER2	Dependent on inputs
		4.4.16 Steam Trap Replacement or Repair	CI-HVC-STRE-V12-260101	Revision	Update to default heating efficiencies	Dependent on inputs
		4.4.21 Linkage-Less Boiler Controls for Space Heating	CI-HVC-LBC-V07-260101	Revision	Re-worked excess air savings factors.	Dependent on inputs
		4.4.22 Oxygen Trim Controls for Space Heating Boilers	CI-HVC-O2TC-V03-260101	Revision	Re-worked excess air savings factors.	Dependent on inputs
		4.4.24 Small Pipe Insulation	CI-HVC-SPIN-V05-260101	Revision	Update to default heating efficiencies	Dependent on inputs
		4.4.26 Variable Speed Drives for HVAC Supply and Return Fans	CI-HVC-VSDF-V11-260101	Revision	Updated measure costs.	N/A
		4.4.27 Energy Recovery Ventilator	CI-HVC-ERVE-V08-260101	Revision	Removed "heat pipes" from tables, as they are sensible-only devices	N/A
		4.4.33 Commercial & Industrial Air Curtain	CI-HVC-AIRC-V08-260101	Revision	Updates to default heating and cooling efficiency assumptions based upon GDS Baseline Study data	Dependent on inputs

Volume	End Use	Measure Name	Measure Code	Change Type	Explanation	Impact on Savings
		4.4.34 Destratification Fan	CI-HVC-DSFN-V09-260101	Revision	Updates to default heating and cooling efficiency assumptions based upon GDS Baseline Study data	Dependent on inputs
		4.4.36 Multi-Family Space Heating Steam Boiler Averaging Controls	CI-HVC-SBAC-V04-260101	Revision	Added second equation option to estimate boiler load.	Dependent on inputs
		4.4.41 Advanced Rooftop Controls	CI-HVC-ARTC-V04-260101	Revision	Addition of multi-speed motor.	Dependent on inputs
		4.4.43 Packaged RTU Sealing	CI-HVC-PRTU-V03-260101	Revision	Updated measure costs.	N/A
		4.4.44 Commercial Ground Source and Ground Water Source Heat Pump	CI-HVC-GSHP-V10-260101	Revision	Addition of language on possible ENERGY STAR retirement. Updated measure costs for residential sized units and avoided replacement costs based on new inflation rate	N/A
		4.4.46 Server Room Temperature Set Back	CI-HVC-SRSB-V02-260101	Revision	Minor updates	N/A
		4.4.48 Small Commercial Thermostats	CI-HVC-THST-V08-260101	Revision	Updates to default HSPF2, SEER2, EER2 and AFUE assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.4.51 Advanced Rooftop Controls with High Rotor Pole Switch Reluctance Motors	CI-HVC-HSRM-V07-260101	Revision	Updates to default SEER2 and EER2 assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.4.55 Commercial Gas Heat Pump	CI-HVC-GFHP-V05-260101	Revision	Fuel switch example updated	N/A
		4.4.56 Commercial Duct Sealing	CI-HVC-DSEAL-V03-260101	Revision	Updates to default HSPF2, SEER2, EER2 and AFUE assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.4.57 Condensate Recovery System	CI-HVC-CNDR-V03-260101	Revision	Removed hot water as only steam systems produce condensate. Fixed example calculation. Update to default heating efficiencies.	N/A
		4.4.58 Steam Trap Monitoring System	CI-HVC-STMS-V2-250101	Errata	Correct deemed table results for process heating based on variable inputs provided.	Dependent on inputs
			CI-HVC-STMS-V3-260101	Revision	Clarifications to Sa calculation section headers to clarify that the space heating formula is for systems ≤ 5psig and the process heating formula is for all other systems > 5 psig. Addition of high pressure steam category. Adjustments to Heat of Vaporization table, average steam trap inlet pressure. Update to default heating efficiencies.	Dependent on inputs
		4.4.60 Variable Refrigerant Flow HVAC System	CI-HVC-VFFY-V4-250101	Errata	Energy saving algorithm for units >65 kBtu/hr should use IEER rather than EER.	Dependent on inputs
			CI-HVC-VFFY-V5-260101	Revision	Incorporated the new efficiency metrics for systems <65,000 Btu/h, SEER2/EER2/HSPF2	Increase

Volume	End Use	Measure Name	Measure Code	Change Type	Explanation	Impact on Savings
		4.4.63 Boiler Blowdown Heat Recovery	CI-HVC-BBHR-V02-260101	Revision	Update to default heating efficiencies	Dependent on inputs
		4.4.64 Steam Vent Condensers	CI-HVC-STVC-V02-260101	Revision	Update to default heating efficiencies	Dependent on inputs
		4.4.66 Steam Leak Repair	CI-HVC-SLKR-V02-260101	Revision	Update to default heating efficiencies	Dependent on inputs
		4.4.67 CRAC/CRAH Electronically Commutated Plug Fans	CI-HVC-CRPF-V01-260101	New	New measure	N/A
		4.4.68 Turbulators	CI-HVC-TRBLR-V01-260101	New	New measure	N/A
		4.4.69 Waterless HVAC Condensate Trap	CI-HVC-WCNDT-V01-260101	New	New measure	N/A
	Lighting	4.5 Lighting End Use	N/A	Revision	Added reference to new excel reference document that provides default wattages for baseline fixture types.	N/A
		4.5.2 Linear Delamping	CI-LTG-DLMP-V04-260101	Revision	Renamed measure. Removed restriction to only allow T12 and T8 fluorescent lamp delamping. Updated baseline mix based on GDS Nonresidential Baseline Study. Default T5 and LED wattages added.	Dependent on inputs
		4.5.3 High Performance and Reduced Wattage T8 Fixtures and Lamps	N/A	Retire	Measure retired	N/A
		4.5.4 LED Bulbs and Fixtures	CI-LTG-LEDB-V19-260101	Revision	Addition of language on possible ENERGY STAR retirement. Measure therefore is now written as DI only with 2 year measure life.	N/A
		4.5.6 LED Traffic and Pedestrian Signals	CI-LTG-LEDT-V05-260101	Revision	Addition of language on possible ENERGY STAR retirement.	N/A
		4.5.9 Multi-Level Lighting Switch	CI-LTG-MLLC-V07-260101	Revision	Updated measure cost. CF calculation updated to be consistent with Occupancy Controls.	Dependent on inputs
		4.5.11 Solar Light Tubes	CI-LTG-STUB-V04-260101	Revision	CF calculation updated to be consistent with Occupancy Controls.	Dependent on inputs
		4.5.12 T5 Fixtures and Lamps	N/A	Retire	Measure retired	N/A
		4.5.15 LED Open Sign	CI-LTG-OPEN-V03-260101	Revision	Removed 20% eligibility criteria. Updated measure savings.	Dependent on inputs
		4.5.18 Ultra-Efficient LED Lighting	CI-LTG-ULED-V02-260101	Revision	Update of measure to use baseline lu/watt assumptions to estimate baseline wattage. Addition of DI application with mid-life adjustment.	Dependent on inputs
	Refrigeration	4.6.2 Beverage and Snack Machine Controls	CI-RFG-BEVM-V05-260101	Revision	Addition of language on possible ENERGY STAR retirement.	N/A

Volume	End Use	Measure Name	Measure Code	Change Type	Explanation	Impact on Savings
		4.6.5 ENERGY STAR Refrigerated Beverage Vending Machine	CI-RFG-ESVE- V06-260101	Revision	Addition of language on possible ENERGY STAR retirement.	N/A
		4.6.13 Add Doors to Open Refrigerated Display Cases	CI-RFG-DOOR-V03-260101	Revision	Updates to default cooling and heating efficiency assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.6.14 Floating Head Pressure Control	CI-RFG-FHP-V02-260101	Revision	Measure cost updated.	N/A
	Compressed Air	4.7.13 Compressed Air Leak Repair	CI-CPA-CALR-V03-260101	Revision	Addition of methodology for estimating CFM leakage based on ultrasonic leak detection decibel readings.	Dependent on inputs
	Shell	4.8.1 Roof Insulation for C&I Facilities	CI-SHL-RINS-V10-260101	Revision	Updates to default cooling and heating efficiency assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.8.2 Spring-Loaded Garage Door Hinge	CI-SHL-SLDH-V02-260101	Revision	Added algorithm and resulting savings outputs for electric heating	Dependent on inputs
		4.8.4 C&I Air Sealing	CI-SHL-CAIR-V05-260101	Revision	Updates to default cooling and heating efficiency assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.8.5 High Speed Overhead Doors	CI-SHL-HSOD-V02-260101	Revision	Updates to default cooling and heating efficiency assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.8.6 Dock Door Seals and Shelter	CI-SHL-DDSS-V02-260101	Revision	Updates to default cooling and heating efficiency assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.8.7 Commercial Wall Insulation	CI-SHL-WINS-V05-260101	Revision	Updates to default cooling and heating efficiency assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.8.8 Commercial Secondary Windows	CI-SHL-CSW-V02-250101	Errata	Fixed Fossil Fuel algorithm to divide by heating system efficiency, not multiply.	Increase
			CI-SHL-CSW-V03-260101	Revision	Updates to default cooling and heating efficiency assumptions based upon GDS Baseline Study data.	Dependent on inputs
		4.8.9 Efficient Windows	CI-SHL-CEFW-V01-260101	New	New measure	N/A
	Miscellaneous	4.9.5 ENERGY STAR Computers	CI-MSC-COMP-V04-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to ENERGY STAR specification Version 9.0 and resultant default savings.	Dependent on inputs
		4.9.6 Advanced Power Strip – Tier 1 Commercial	CI-MSC-APSC-V06-260101	Revision	Added clarification that midstream should use same ISR as kit programs. Update to assumption of office open hours	Decrease
		4.9.7 High Efficiency Transformer	CI-MSC-TRNS-V04-260101	Revision	Updated load factor and source	Decrease
		4.9.15 ENERGY STAR Low Wattage Uninterruptible Power Supply	CI-MSC-UPSE-V05-260101	Revision	Addition of language on possible ENERGY STAR retirement.	N/A
		4.9.25 Virtual AMI Driven Commissioning (VCx)	CI-MSC-VCx-V01-260101	New	New measure	N/A

Volume	End Use	Measure Name	Measure Code	Change Type	Explanation	Impact on Savings
Volume 3: Residential Measures	Appliances	5.1.1 ENERGY STAR Air Purifier/Cleaner	RS-APL-ESAP-V08-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to ENERGY STAR Version 3.0, hours of use and measure cost. Default savings updated.	Dependent on inputs
		5.1.2 ENERGY STAR Clothes Washer	RS-APL-ESCL-V14-260101	Revision	Addition of language on possible ENERGY STAR retirement.Update to %Electric_Dryer, %Electric_DHW assumptions based on GDS Baseline Study and recalculation of all deemed savings.	Dependent on inputs
		5.1.3 ENERGY STAR Dehumidifier	RS-APL-ESDH-V12-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to ENERGY STAR specification v6.0 effective 10/01/2025, and resulting deemed savings results.	Dependent on inputs
		5.1.4 ENERGY STAR Dishwasher	RS-APL-ESDI-V12-260101	Revision	Addition of language on possible ENERGY STAR retirement.%Electric_DHW and %Fossil_DHW updated based on GDS baseline study. Recalculation of deemed savings.	Dependent on inputs
		5.1.5 ENERGY STAR Freezer	RS-APL-ESFR-V06-260101	Revision	Addition of language on possible ENERGY STAR retirement.	N/A
		5.1.6 ENERGY STAR, CEE Tier 2 or CEE Tier 3 Refrigerator	RS-APL-ESRE-V12-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to future avoided replacement costs based on 2026 inflation rate.	N/A
		5.1.7 ENERGY STAR and CEE Tier 2 Room Air Conditioner	RS-APL-ESRA-V12-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to future avoided replacement costs based on 2026 inflation rate. Update to CEERexist assumptions.	Decrease
		5.1.9 Room Air Conditioner Recycling	RS-APL-RARC-V05-260101	Revision	Addition of separate assumptions for IQ Room AC units recycled reflecting usage assumptions consistent with the Room AC measure. Update to CEERexist assumptions.	Increase for IQ
		5.1.10 ENERGY STAR Clothes Dryer	RS-APL-ESDR-V08-260101	Revision	Addition of language on possible ENERGY STAR retirement. Clarification to use Actual CEFeff if unknown.	N/A
		5.1.11 ENERGY STAR Water Coolers	RS-APL-WTCL-V03-260101	Revision	Addition of language on possible ENERGY STAR retirement.	N/A
		5.1.12 Ozone Laundry	RS-APL-OZNE-V08-260101	Revision	%Electric_DHW and %Fossil_DHW updated based on GDS baseline study.	Dependent on inputs
		5.1.14 Residential Induction Cooking Appliances	RS-MSC-INDC-V04-260101	Revision	Update to measure to apply prescriptive consumption values. Measure cost update. %cooling assumptions provided by market type based on GDS baseline study. %Electric_Heat and %Fossil_Heat provided by market and utility based on GDS baseline study.	Increase
		5.1.17 ENERGY STAR All-in-One Clothes Washer-Dryer	RS-APL-ACWD-V02-260101	Revision	Addition of language on possible ENERGY STAR retirement. Algorithms for fossil DHW added to both non-fuel switch and fuel switch sections. %Electric_DHW and %Fossil_DHW updated based on GDS baseline study.	Dependent on inputs

Volume	End Use	Measure Name	Measure Code	Change Type	Explanation	Impact on Savings
		5.1.18 Residential Refrigerator Seal Replacement	RS-APL-RRSR-V01-260101	New	New measure	N/A
	Consumer Electronics	5.2.3 ENERGY STAR Televisions	RS-CEL-TVS-V03-260101	Revision	Addition of language on possible ENERGY STAR retirement.	N/A
		5.2.4 Smart Sockets	RS-CEL-SSOC-V02-260101	Revision	Updated measure costs	N/A
	HVAC	5.3.1 Centrally Ducted Air Source Heat Pump (Central, Ductless and Portable)	RS-HVC-ASHP-V16-260101	Revision	Addition of Room AC being appropriate baseline for mobile homes when the existing condition. Addition of Electric Furnace Fan Savings calculation when appropriate. Updated measure costs. Update to Room AC existing efficiency assumptions.	Dependent on inputs
		5.3.3 Central Air Conditioning	RS-HVC-CAC1-V14-260101	Revision	Replacing efficient specifications from ENERGY STAR (which is being sunset in February 2026) with the Consortium for Energy Efficiency (CEE). Update to capacity assumptions now by market sector, based on GDS Baseline Study. Update to mobile home Room AC baseline efficiency assumptions. Updated measure costs.	Dependent on inputs
		5.3.4 Duct Insulation and Sealing	RS-HVC-DINS-V14-260101	Revision	Addition of savings for electric furnaces. %Electric v %Fossil Heat, unknown efficiency and %cooling assumptions provided by market type based on GDS baseline study. Adding distribution efficiency to cooling efficiency assumptions.	Dependent on inputs
		5.3.6 Gas High Efficiency Boiler	RS-HVC-GHEB-V13-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to measure cost.	N/A
		5.3.7 Gas High Efficiency Furnace	RS-HVC-GHEF-V15-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to measure cost. Update to deemed capacity based on GDS Baseline study.	Decrease
		5.3.8 Ground Source Heat Pump	RS-HVC-GSHP-V16-260101	Revision	Addition of language on possible ENERGY STAR retirement. Update to measure cost.	N/A

		5.7.5 Tree Planting	RS-MSC-TREE-V02-260101	Revision	Addition of savings for room AC cooled homes. %Electric_Heat and %Fossil_Heat, Unknown efficiency and %cooling assumptions provided by market type based on GDS baseline study. Update to DUA factor. Adding distribution efficiency to cooling efficiency assumptions.	Dependent on inputs
		5.7.6 Smart Irrigation Controls	RS-MSC-IRGN-V01-260101	New	New measure	Dependent on inputs

Table 1.4: Summary of Attachment A: IL-NTG Methods Revisions

IL-TRM Volume	Sectors	Protocol Name	Change Type	Explanation
Vol. 4	Commercial, Industrial, and Public Sector	N/A	Revision	Revision to Table 3-1 regarding timing horizon for Midstream programs and text preceding the table.
Vol. 4	Commercial, Industrial, and Public Sector	Core Non-Residential Protocol	Revision	Revision to Consistency Checks subsection
Vol. 4	Commercial, Industrial, and Public Sector	C&I New Construction Protocol	Revision	Formatting revision to cross-reference of Figure 3-2 in the text
Vol. 4	Residential and Low Income Sector Protocols	Residential New Construction Protocol	Revision	Formatting revision – removed extra space
Vol. 4	Cross-Sector Protocols	Midstream FR Protocol	Revision	Revision to the Midstream FR algorithm

1.3 Enabling ICC Policy

This Illinois Statewide Technical Reference Manual (TRM) was developed to comply with the Illinois Commerce Commission (ICC or Commission) Final Orders from the electric and gas Utilities' Energy Efficiency Plan dockets.[6] In the Final Orders, the ICC required the utilities to work with the Illinois Department of Commerce and Economic Opportunity (DCEO) and the Illinois Energy Efficiency Stakeholder Advisory Group (SAG) to develop a statewide TRM. See, e.g., ComEd's Final Order *(Docket No. 10-0570, Final Order[7] at 59-60, December 21, 2010);* Ameren's Final Order *(Docket No. 10-0568, Order on Rehearing[8] at 19, May 24, 2011);* Peoples Gas/North Shore Gas' Final Order *(Docket No. 10-0564, Final Order[9]at 76, May 24, 2011),* and Nicor's Final Order *(Docket No. 10-0562, Final Order[10] at 30, May 24, 2011).*

As directed in the Utilities' Efficiency Plan Orders, the SAG had the opportunity to, and also participated in, every aspect of the development of the TRM. Interested members of the SAG participated in weekly teleconferences to review, comment, and participate in the development of the TRM. The active participants in the TRM were designated as the "Technical Advisory Committee" (TAC). The TAC participants include representatives from the following organizations:

- the Utilities (ComEd, Ameren IL, Nicor Gas, Peoples Gas/North Shore Gas),
- Implementation contractors,
- Illinois Department of Commerce and Economic Opportunity (DCEO),
- the independent evaluators,
- ICC Staff,
- the Illinois Attorney General's Office (AG),
- Natural Resources Defense Council (NRDC),
- the Environmental Law and Policy Center (ELPC),
- the Citizen's Utility Board (CUB),
- The University of Illinois at Chicago,
- Future Energy Enterprises,
- Issue-specific invited participants, including; Geothermal Alliance of Illinois, the Geothermal Exchange Organization, Embertec, Trane, TrickleStar, Oracle, Google Nest, Ecobee, and US EPA ENERGY STAR.

1.4 Development Process

Each version of the IL-TRM is approved by the Commission in the ICC Dockets listed below, and can all be found on the ICC webpage; https://www.icc.illinois.gov/programs/illinois-statewide-technical-reference-manual-for-energy-efficiency. Errata to the IL-TRM versions may also be found on that ICC IL-TRM webpage.

TRM Version	ICC Docket Number
Version 1.0	12-0528
Version 2.0	13-0437
Version 3.0	14-0189

[6] The Illinois Utilities subject to this TRM include: Ameren Illinois Company d/b/a Ameren Illinois (Ameren), Commonwealth Edison Company (ComEd), The Peoples Gas Light and Coke Company and North Shore Gas Company, and Northern Illinois Gas Company d/b/a Nicor Gas.

TRM Version	ICC Docket Number
Version 4.0	15-0187
Version 5.0	16-0171
2018 Version 6.0	17-0106
2019 Version 7.0	18-1605
2020 Version 8.0	19-0954
2021 Version 9.0	20-0741
2022 Version 10.0	21-0751
2023 Version 11.0	22-0603
2024 Version 12.0	23-0709
2025 Version 13.0	

The policies surrounding the applicability and use of the IL-TRM in planning, implementation, and evaluation were originally established by the Commission in ICC Docket No. 13-0077,[11] and most recently in ICC Docket Nos. 17-0270[12] and 19-0983.[13]

This document represents the 14th version of the IL-TRM and applies to Section 8-103B and Section 8-104 energy efficiency programs. It contains a series of new measures, as well as a series of errata items[14] and updates to existing measures already present in the first 13 versions. Like the previous versions, it is a result of an ongoing review process involving the Illinois Commerce Commission (ICC) Staff (Staff or ICC Staff), the Utilities, the Evaluators, the SAG TAC, and the SAG. VEIC meets with the SAG and/or the TRM TAC at least once each month to create a high level of transparency and vetting in the development of this TRM.

Measure requests that are submitted by interested parties are ranked based on the following criteria to determine the approximate priority level for order of inclusion in the TRM:

1. High Priority
    a. For those existing measures that make up a significant portion of a utilities' portfolio and/or where the impact of the requested change is high
    b. For new measures where plans are in place to implement in the next program year
2. Medium Priority
    a. For existing measures that are a less significant percent of a utilities' portfolio and value change will not have a significant impact
    b. For new measures where a savings value is estimated but implementation plans not yet developed
3. Low Priority
    a. For existing measures that represent a very small percent of a utilities' portfolio
    b. For new measures that are just beginning to be explored and will not be implemented in the next program year

These rankings are used to align budget and schedule constraints with desired updates from the TRM.

As measure requests are finalized leading up to the next update of the TRM, weekly TAC meetings are often scheduled to maximize collaboration and visibility into the measure characterization process. Where consensus does

[14] Errata as well as links to the official IL-TRM documents, dockets, and policy documents are available on the following ICC webpage: http://www.icc.illinois.gov/Electricity/programs/TRM.aspx

not emerge on specific measures or issues, those items are identified in a memo. As a result, this TRM represents a broad consensus amongst the SAG and TAC participants. In keeping with the goal of transparency, all of the comments and their status to date are available through the TAC SharePoint web site, https://portal.veic.org.

For each measure characterization, this TRM includes engineering algorithm(s) and a value(s) for each parameter in the equation(s). These parameters have values that fall into one of three categories: a single deemed value, a lookup table of deemed values or an actual value such as the capacity of the equipment. The TRM makes extensive use of lookup tables because they allow for an appropriate level of measure streamlining and customization within the context of an otherwise prescriptive measure.

Accuracy is the overarching principle that governs what value to use for each parameter. When it is explicitly allowed within the text of the measure characterization, the preferred value is the actual or on-site value for the individual measure being implemented. The *deemed values*[15] in the lookup tables are the next most accurate choice, and in the absence of either an actual value or an appropriate value in a lookup table, the single, *deemed value* should be used. As a result, this single, *deemed value* can be thought of as a default value for that particular input to the algorithm.

A single *deemed savings estimate* is produced by any given combination of an algorithm and the allowable input values for each of its parameters. In cases where lookup tables are provided, there is a range of deemed savings estimates that are possible, depending on site-specific factors such as equipment capacity, location and building type.

Algorithms and their parameter values are included for calculating estimated:

- Gross annual electric energy savings (kWh)
- Gross annual natural gas energy savings (therms)
- Gross electric summer coincident peak demand savings (kW)

To support cost-effectiveness and cumulative persisting annual savings (CPAS) calculations, parameter values are also included for:

- Incremental costs ($)
- Measure life (years)
- Operation and maintenance costs ($)
- Water (gal) and other resource savings where appropriate.

1.4.1 Reliability Review

The process of incorporating new and better information into the TRM occurs annually as new measures and errors are identified, program designs change, old measures are dropped from programs, or other external events (such as code and standard changes or new evaluations and other data) warrant a review of assumptions. However, not all measures have updates triggered by such events, and some measures continue to appear in the TRM without ongoing review. Short of proactively identified issues that would trigger an update to a TRM characterization, a regular reliability review should be undertaken to assess that the information in older measures is still relevant and reliable. This review will include a general appraisal of reasonableness and continued program relevancy and an update of any assumptions to reflect new information.

To ensure that measures initially developed in the past and not recently revisited are updated and retired as needed, each measure is given a Review Deadline – a date that triggers a reliability review. This Review Deadline is established for each measure based on factors such as expected revisions to energy codes or federal standards; knowledge of upcoming evaluation or research efforts; knowledge of rapidly changing technology, cost, baselines, or other factors; or expected shifts in current customer practices. No Review Deadline is longer than six years from the date of the

[15] Emphasis has been added to denote the difference between a “deemed value” and a “deemed savings estimate”. A deemed value refers to a single input value to an algorithm, while a deemed savings estimate is the result of calculating the end result of all of the values in the savings algorithm.

initial characterization or last update of a measure. The TRM Administrator will propose Review Deadlines for each measure, and they are reviewed and approved by the TAC. The Review Deadline for each measure is indicated in the measure characterization within the TRM. For example, a Review Deadline specified as 1/1/2027 means that the measure will be reviewed no later than the annual IL-TRM update process that occurs in 2026, in advance of the 1/1/2027 Review Deadline. Following a review and/or update, a new Review Deadline will be assigned to that measure.

2 Organizational Structure

The organization of this document follows a three-level format. These levels are designed to define and clarify what the measure is and where it is applied.

1. **Market Sectors Volumes**[16]
    - This level of organization specifies the type of customer the measures apply to, either Commercial and Industrial (provided in Volume 2), Residential (provided in Volume 3), or cross-cutting measures, such as Behavior Persistence (provided in Volume 4, together with Attachments including the documentation of Illinois Statewide Net-to-Gross Methodologies, Guidelines for EULs for Custom Measures, and Framework for Counting Market Transformation Savings in Illinois).
    - Answers the question, "What category best describes the customer?"
2. **End-use Category**
    - This level of organization represents most of the major end-use categories for which an efficient alternative exists. The following table lists all of the end-use categories in this version of the TRM.
    - Answers the question, "To what end-use category does the measure apply?"

Table 2.1: End-Use Categories in the TRM[17]

Volume 2: Commercial and Industrial Market Sector	Volume 3: Residential Market Sector	Volume 4: Cross-Cutting Measures and Attachments
Agricultural Equipment	Appliances	Behavior
Food Service Equipment	Consumer Electronics	System Wide
Hot Water	Hot Water	
HVAC	HVAC	
Lighting	Lighting	
Refrigeration	Shell	
Compressed Air	Miscellaneous	
Shell		
Miscellaneous		

3. **Measure & Technology**
    - This level of organization represents individual efficient measures such as CFL lighting and LED lighting, both of which are individual technologies within the Lighting end-use category.
    - Answers the question, "What technology defines the measure?"

This organizational structure is silent on which fuel the measure is designed to save; electricity or fossil fuels. By organizing the TRM this way, measures that save on both fuels do not need to be repeated. As a result, the TRM will be easier to use and to maintain.

2.1 Measure Code Specification

In order to uniquely identify each measure in the TRM, abbreviations for the major organizational elements of the TRM have been established. When these abbreviations are combined and delimited by a dash ('-') a unique, 18-character alphanumeric code is formed that can be used for tracking the measures and their associated savings estimates. Measure codes appear at the end of each measure and are structured using five parts.

[16] Note that the Public sector buildings and low income measures are not listed as a separate Market Sector. The Public building type is one of a series of building types that are included in the appropriate measures in the Commercial and Industrial Sector.
[17] Please note that this is not an exhaustive list of end-uses and that others may be included in future versions of the TRM.

Code Structure = Market + End-use Category + Measure + Measure Version # + Effective Date

For example, the commercial boiler measure is coded: "CI-HVC-BLR_-V01-120601"

Table 2.2: Measure Code Specification Key

Market (@@)	End-use (@@@)	Measure (@@@@)	Version (V##)	Effective Date
CI (C&I)	AGE (Agricultural)	BLR_	V01	YYMMDD
RS (Residential)	APL (Appliances)	T5FX	V02	YYMMDD
CC (Cross-Cutting)	BEH (Behavior)	T8FX	V03	YYMMDD
	CEL (Consumer Electronics)	…	…	…
	CPA (Compressed Air)			
	FSE (Food Service)			
	HVC (HVAC)			
	HWE (Hot Water)			
	LTG (Lighting)			
	MSC (Miscellaneous)			
	RFG (Refrigeration)			
	SHL (Shell)			
	SYS (System-wide)			

2.2 Components of TRM Measure Characterizations

Each measure characterization uses a standardized format that includes at least the following components. Measures with a higher level of complexity may have additional components, but also follow the same format, flow and function.

DESCRIPTION

Brief description of measure stating how it saves energy, the markets it serves and any limitations to its applicability.

DEFINITION OF EFFICIENT EQUIPMENT

Clear definition of the criteria for the efficient equipment used to determine delta savings. Including any standards or ratings if appropriate.

DEFINITION OF BASELINE EQUIPMENT

Clear definition of the efficiency level of the baseline equipment used to determine delta savings including any standards or ratings if appropriate. If a Time of Sale measure the baseline will be new base level equipment (to replace existing equipment at the end of its useful life or for a new building). For Early Replacement or Early Retirement measures the baseline is the existing working piece of equipment that is being removed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected duration in years (or hours) that the measure is expected to provide savings. Please see "Measure Life" in Section 3.5 Glossary. This is often based on the rated technical life of the equipment but may also be adjusted in consideration of the potential for users to remove or remodel and to allow for breakages or imperfect operation. If the savings of a population is expected to *decline* due to outcomes such as the overriding of settings or poorly maintaining equipment, a midlife adjustment should be used to reduce the lifetime savings [18]; however, the measure lifetime should still reflect the technical lifetime (i.e. total years any savings are expected to occur).

[18] In rare cases, for example residential Home Energy Report (HER) type programs, in may be appropriate to have savings decay each year throughout the measure life rather than in a midlife adjustment.

If an early replacement measure, the assumed Remaining Useful Life (RUL) of the existing unit is also provided.

DEEMED MEASURE COST

For time of sale measures, incremental cost from baseline to efficient is provided. Installation costs should only be included if there is a difference between each efficiency level. For Early Replacement the full equipment and install cost of the efficient installation is provided in addition to the full deferred hypothetical baseline replacement cost. See '3.9 Measure Incremental Cost Definition' for more detailed information concerning incremental cost calculations.

LOADSHAPE

The appropriate loadshape to apply to electric savings is provided.

COINCIDENCE FACTOR

The summer coincidence factor is provided to estimate the impact of the measure on the utility's system peak – defined as 1PM to hour ending 5PM on non-holiday weekdays, June through August.

Algorithm

CALCULATION OF ENERGY SAVINGS

Algorithms are provided followed by list of assumptions with their definition.

If there are no Input Variables, there will be a finite number of Output values. These will be identified and listed in a table. Where there are custom inputs, an example calculation is often provided to illustrate the algorithm and provide context.

ELECTRIC ENERGY SAVINGS

SUMMER COINCIDENT PEAK DEMAND SAVINGS

FOSSIL FUEL SAVINGS

WATER IMPACT DESCRIPTIONS AND CALCULATION

DEEMED O&M COST ADJUSTMENT CALCULATION

Only required if the operation and maintenance cost for the efficient case is different to the baseline. See '3.9 Measure Incremental Cost Definition' for information on the appropriate treatment of O&M costs.

MEASURE CODE

REVIEW DEADLINE

If not otherwise updated as part of an identified new TRM issue request before this Review Deadline, the measure will undergo a reliability review for reasonableness, continued program relevancy, and update of material assumptions during the update cycle prior to this deadline.

2.3 Variable Input Tables

Many of the measures in this TRM require the user to select the appropriate input value from a list of inputs for a given parameter in the savings algorithm. Where the TRM asks the user to select the input, look-up tables of allowable values are provided. For example, a set of input parameters may depend on building type; while a range of values may be given for each parameter, only one value is appropriate for any specific building type. If no table of alternative inputs is provided for a particular parameter, then the single deemed value will be used, unless the

measure has a custom allowable input.

2.3.1 C&I Custom Value Use in Measure Implementation

This section defines the requirements for capturing Custom variables that can be used in place of defaults for select assumptions within the prescriptive measures defined in this statewide TRM. This approach is to be used when a variable in a measure formula can be replaced by a verifiable and documented value that is not presented in the TRM. This approach assumes that the algorithms presented in the measure are used as stated and only allows changes to certain variable values and is not a replacement algorithm for the measure. A custom variable is when customer input is provided to define the number, or the value is measured at the site. Custom values can also be supplied from product data of the measure installed. In certain cases, the custom data can be provided from a documented study or report that is applicable to the measure. Custom variables and potential sources are clearly defined in the specific measures where "Actual", or "Custom" is noted.

In exceptional cases where the participant, program administrator, and independent evaluator all agree that the TRM algorithm for a particular energy efficiency measure does not accurately characterize the energy efficiency measure within a project due to the complexity in the design and configuration of the particular energy efficiency project, a more comprehensive custom engineering and financial analysis may be used that more accurately incorporates the attributes of the measure in the complex energy efficiency project. In such cases and consistent with Commission policy adopted in ICC Docket No. 17-0270, Program Administrators are subject to retrospective evaluation risk (retroactive adjustments to savings based on ex post evaluation findings) for such projects using customized savings calculations.

2.4 Program Delivery & Baseline Definitions

The measure characterizations in this TRM are not grouped by program delivery type. As a result, the measure characterizations provided include information and assumptions to support savings calculations for the range of program delivery options commonly used for the measure. The organizational significance of this approach is that multiple baselines, incremental costs, O&M costs, measure lives and in-service rates are included in the measure characterization(s) that are delivered under two or more different program designs. Values appropriate for each given program delivery type are clearly specified in the algorithms or in look-up tables within the characterization.

Care has been taken to clearly define in the measure's description the types of program delivery that the measure characterization is designed to support. However, there are no universally accepted definitions for a particular program type, and the description of the program type(s) may differ by measure. Nevertheless, program delivery types can be generally defined according to the following baseline definitions. These are the definitions used in the measure descriptions, and, when necessary, individual measure descriptions may further refine and clarify these definitions of program delivery type.

Baseline Definitions

The energy savings for an efficiency measure is derived, in significant part, by estimating the difference between baseline efficiency and the efficiency of the measure in question. Baselines are the standard practices regarding investment in efficiency (whether measures or operations) that efficiency programs are designed to change. They address the first (gross savings) component of the question "what would have occurred absent the efficiency program?" The answer to that question is completed when making net-to-gross adjustments.

Specific measure baselines are to be covered in the TRM; however, general descriptions and guidance regarding baselines are included here.

Baselines for calculating gross savings can differ depending on the type of efficiency initiative:[19]

- **Time of Sale (TOS)**

[19] Note that best efforts should be made to ensure that net-to-gross adjustments shall be estimated relative to the specific gross savings baselines for a given product or program.

This type of initiative is designed to influence the decision of a customer who is going to purchase a new product independent of an efficiency program, with the program only influencing the *efficiency level* of the product purchased (not whether a product would be purchased). In most cases, the baseline for time of sale initiatives is the least efficient product the customer is permitted to purchase by law (i.e. complies with state and federal product efficiency standards). However, when there is no equipment available at those legal minimums the baseline shall be adjusted to the TAC agreed efficiency that represents the least efficient products that would be commonly purchased in the Illinois market absent efficiency programs. For products for which there are no legal minimum efficiency requirements, the baseline should be the TAC agreed efficiency that represents the least efficient products that would be commonly purchased in the Illinois market absent efficiency programs.

- **New Construction (NC)**

  This type of initiative is designed to influence the design and construction of new buildings and major renovations to existing buildings, including decisions regarding which products will be installed in such buildings. Note that it only covers cases in which the independent evaluator concludes that the customer was planning the new construction or major renovation project independent of an efficiency program; cases in which an efficiency program was what triggered a customer to renovate an existing building are treated under the Retrofit or Early Replacement program discussions below. The default baseline for new construction initiatives shall be the applicable efficiency codes (including state or local building codes) and/or product efficiency standards in effect at the time a permit was issued. However, if and when the TAC accepts an assessment of baseline construction practices documenting typical construction practice different than code, whether lower or higher, the results of such study will become the baseline for estimating new construction project savings.[20] A baseline that is lower than code can be estimated and used only when the TAC accepts study results demonstrating that the typical industry practice in some geographic regions or market segments is for construction or renovation at a level of efficiency below code.[21]

- **Early Replacement (EREP)**

  This type of initiative is designed to convince customers to replace functional equipment earlier than they otherwise would. In such cases there shall be a dual baseline, with the existing equipment efficiency (i.e., the efficiency of the equipment being replaced) being the baseline for the remaining useful life of the equipment and a potentially different (typically higher) efficiency for standard *new* products (consistent with the time of sale baselines, as adjusted for any known changes to future codes or standards) being used as baseline for the remaining life of the efficiency measure. Note that for a measure to be treated as "early replacement", the existing equipment being replaced early must be in good functioning condition or require minimal repair (i.e., it is reasonable to conclude that it could have continued to function in the absence of the program).

  Additional requirements may be developed by the TAC and applied to certain measures to ensure appropriate use of early replacement assumptions, such as a maximum existing unit age, and/or to help ensure a positive cost-effectiveness result is achieved, such as requiring maximum existing unit efficiency eligible for early replacement.

[20] Baseline efficiency levels set above (i.e., more efficient) than a code/standard baseline are only possible for measures or measure bundles with efficiency alternatives that fall between the relevant code/standard and the efficiency requirement of the program (i.e., an "intermediate efficiency" level), and are only possible in cases where the independent evaluator determines that NTG is not capturing the impact of these intermediate efficiency levels.

[21] This would include cases in which utility programs endeavor to improve code compliance and can measure such improvement. It would also include situations in which a compelling case could be made that a utility initiative was necessary to enable a more efficient state or local code to be adopted (at least sooner than it otherwise would have been).

Note that in addition to the above criterion, the independent evaluator must conclude that the program caused the customer to replace their existing equipment before the end of its useful life to award the additional net savings from the early replacement. Any adjustment related to this concept is handled in the net-to-gross ratio and is not addressed in gross savings.

- **Early Retirement (ERET)**

  This type of initiative is designed to convince customers to remove (and not replace) equipment that would otherwise continue to remain functional (and consume energy). In such cases, the baseline is the existing efficiency of the equipment being removed. Note that for a measure to be treated as "early retirement", the existing equipment being removed must be in good functioning condition.

- **Retrofit (RF)**

  This type of initiative is designed to convince customers to add efficiency features and/or practices to energy consuming products, systems, or buildings. For such measures, the baseline is the existing level of efficiency of the products, systems or buildings to which efficiency features are being added. This is the case even if the act of adding efficiency features and/or practices triggers application of a state or local code because such a trigger would not have occurred absent the efficiency program.

Other Program Delivery Types

Additional program delivery types may have their own distinct assumptions (e.g., In Service Rates) provided within a measure characterization, for example:

- **Direct Install (DI)** - A program where measures are installed by a program representative during a site visit.
- **Efficiency Kits (KITS)** - A program where measures are provided to customers and in an Efficiency Kit and may be distributed through a number of channels (e.g. online ordering, schools, community events, trade shows, etc.).

2.4.1 Default Measure Type for Program Delivery Methods

The decision as to whether a measure is a Time of Sale or Early Replacement measure is critical to ensure the appropriate baseline is used to calculate the measure savings and the appropriate costs are applied. This decision could include consideration of:

- The functionality of or required repair cost of the existing equipment
- The age of the existing equipment and it's estimated remaining useful life
- The role of the Program Administrator or a representative / contractor (referred herein as PA) in the decision to replace the equipment
- The importance of the incentive and/or contact with the PA in the decision to replace the equipment
- The timing of replacement in relation to regular maintenance or recapitalization upgrade schedules

The default position for measures in some common program designs are provided below, however diverging from this default is possible.

Program Type	Default Measure Type
Direct Install	Early Replacement
Audits	Early Replacement if results in replacing functioning equipment
Standard Rx Lighting Program (one-to-one fixture replacement)	Time of Sale
Standard Rx Lighting Program (lighting system redesign or delamping)	Early Replacement or Early Retirement

Program Type	Default Measure Type
Other Standard Rx Programs	Time of Sale or Retrofit
Downstream	Time of Sale
Midstream	Time of Sale
Upstream	Time of Sale

Diverging from the default could be based upon either:

- A unit by unit site specific basis as governed by guidance established by the TAC and clearly documented in the TRM, for example Residential HVAC early replacement measures require verifying the unit is functional or that required repairs cost less than 20% of the cost of a new baseline unit.
- A TAC agreed divergence could be established on a program/measure level supported by an independent evaluation to demonstrate that the presence of the incentive and/or contact with the Program (for example via targeted marketing material), was significant enough to result in the participants replacing functioning equipment that they would not otherwise have done.

It may be appropriate to apply a deemed percent split of Time of Sale and Early Replacement assumptions based on these evaluation results, noting that it may be observed that different markets or participant groups have very different deemed percentages of early replacements (e.g., low income populations are less likely to replace functioning units early without program involvement).

It is also possible that a project within a property may include both Early Replacement *and* Time of Sale measures. Classification of part of a project as Early Replacement, as defined above, does not preclude classification of another portion of the project as Time of Sale and vice versa.

3 Assumptions

The information contained in this TRM contains VEIC's recommendations for the content of the Illinois TRM. Sources that are cited within the TRM have been chosen based on two priorities, geography and age. Whenever possible and appropriate, VEIC has incorporated Illinois-specific information into each measure characterization. The Business TRM documents from Ameren and ComEd were reviewed, as well as program and measure specific data from evaluations, efficiency plans, and working documents.

The assumptions for these characterizations rest on our understanding of the information available. In each case, the available Illinois and Midwest-specific information was reviewed, including evaluations and support material provided by the Illinois Utilities.

When Illinois or region-specific evaluations or data were not available, best practice research and data from other jurisdictions were used, often from west- and east-coast states that have allocated large amounts of funding to evaluation work and to refining their measure characterization parameters. As a result, much of the most-defensible information originates from these regions. In every case, VEIC used the most-recent, well-designed, and best-supported studies and only if it was appropriate to generalize their conclusions to the Illinois programs.

3.1 Footnotes & Documentation of Sources

Each new and updated measure characterization is supported by a work paper, which is posted to the SharePoint web site (https://portal.veic.org).[22] Both the work paper and the measure characterizations themselves use footnotes to document the references that have been used to characterize the technology. The reference documents are too numerous to include in an Appendix and have instead been posted to the TRM's SharePoint website. These files can be found in the 'Sources and Reference Documents' folder in the main directory, and are also posted to the SAG's public web site (http://www.ilsag.info/technical-reference-manual.html).

3.2 General Savings Assumptions

The TRM savings estimates are expected to serve as average, representative values, or ways to calculate savings based on program-specific information. All information is presented on a per-measure basis. In using the measure-specific information in the TRM, it is helpful to keep the following notes in mind.

- All estimates of energy (kWh or therms) and peak (kW) savings are for first-year savings, not lifetime savings. Note all fossil fuel savings are presented in therms, but may be converted to other fuels using the conversion factors provided in section 3.12.1.
- Unless otherwise noted, measure life is defined by the detailed definition provided in 3.5 Glossary.
- Where deemed values for savings are provided, they represent the average energy (kWh or therms) or peak (kW) savings that could be expected from the average of all measures that might be installed in Illinois in the program year.
- In general, the baselines included in the TRM are intended to represent average conditions in Illinois. Some are based on data from the state, such as household consumption characteristics provided by the Energy Information Administration. Some are extrapolated from other areas, when Illinois data are not available.

3.3 Shifting Baseline Assumptions

The TRM anticipates the effects of changes in efficiency codes and standards on affected measures. When these changes take effect, a shift in the baseline is usually required. This complicates the measure savings estimation somewhat and will be handled in future versions of the TRM by describing the choice of and reasoning behind a shifting baseline assumption. In this version of the TRM, this applies to CFLs and T5/T8 Linear Fluorescents, Furnaces and Early Replacement Measures.

[22] To gain access to the SharePoint web site, please contact the TRM Administrator at iltrmadministrator@veic.org.

3.3.1 Linear Fixture Baseline Assumptions

Linear LED Fixtures

In July 14, 2012, Federal Standards were enacted that were expected to eliminate T-12s as an option for linear fluorescent fixtures. Through v3.0 of the TRM, it was assumed that the T-12 would no longer be baseline for retrofits from 1/1/2016. However, due to significant loopholes in the legislation, T-12 compliant product is still freely available, and in Illinois T-12s continue to hold a significant share of the existing market. Therefore, measures allow T12 as an existing fixture for early replacements, with a midlife adjustment to an assumed new baseline fixture after the assumed burn out of the existing fixture.

3.3.2 Early Replacement Baseline Assumptions

A series of measures have an option to choose an Early Replacement Baseline if the following conditions are met:

- The existing unit is operational when replaced, or
- The existing unit requires minor repairs[23]
- All other conditions will be considered Time of Sale.

Maximum efficiencies for measures to be considered early replacement should be determined by the program to ensure cost-effectiveness.

3.3.3 Furnace Baseline

The prior national standard for residential oil and gas furnaces was 78% AFUE. DOE raised the standard in 2007 to 80% AFUE, effective 2015. However, virtually all furnaces on the market have an AFUE of 80% or better, which prompted states and environmental and consumer groups to sue DOE over its 2007 decision. In April 2009, DOE accepted a "voluntary remand" in that litigation. In October 2009, manufacturers and efficiency advocates negotiated an agreement that, for the first time, included different standard levels in three climate regions: the North, South, and Southwest. DOE issued a direct final rule (DFR) in June 2011 reflecting the standard levels in the consensus agreement. The DFR became effective on October 25, 2011 establishing new standards: In the North, most furnaces will be required to have an AFUE of 90%. The 80% AFUE standard for the South and Southwest will remain unchanged at 80%. Oil furnaces will be required to have an AFUE of 83% in all three regions. The amended standards will become effective in May 2013 for non-weatherized furnaces and in January 2015 for weatherized furnaces. DOE estimates that the standards will save about 3.3 quads (quadrillion Btu) of energy over 30 years and yield a net present value of about $14 billion at a 3 percent discount rate.

Update*:* On January 14th, 2013, the U.S. Department of Energy (DOE) proposed to settle a lawsuit brought by the American Public Gas Association (APGA) that seeks to roll back gas furnace efficiency standards. As a result, the new standards, completed in 2011 and slated to take effect in May 2013, would be eliminated in favor of yet another round of DOE hearings and studies.

A 2021 Final Interpretive Rule ("2021-01-15 Energy Conservation Program for Appliance Standards: Energy Conservation Standards for Residential Furnaces and Commercial Water Heaters; Notification of final interpretive rule") provides the following language:

> *"..in the context of residential furnaces, commercial water heaters, and similarly-situated products / equipment, use of non-condensing technology (and associated venting) constitute a performance-related "feature" under the Energy Policy and Conservation Act (EPCA) that cannot be eliminated through adoption of an energy conservation standard."*

Since setting a standard of 90% would require a condensing furnace and this language indicates that non-condensing units cannot be eliminated through a standard – it is assumed that a future 90% AFUE standard is unlikely. Therefore in v10, a prior assumption that the 90% standard would be in place following the remaining useful life of an existing

[23] The Technical Advisory Committee agreed that if the cost of repair is less than 20% of the new baseline replacement cost it can be considered early replacement.

furnace has been removed.

3.4 Carryover Savings / Deferred Installs

Carryover savings, or savings from deferred installs, are defined as savings counted in the current year from measures bought or distributed in previous years. Please see the measure specific sections of the TRM to determine if the relevant lighting measure and program delivery calls for deferred installations (year 2 and year 3 installations).

Deferred installations from lighting measures are characterized in relevant sections of the TRM (currently only applicable to TLEDs in '4.5.4 LED Bulbs and Fixtures'). Broadly, the characterization is as follows:

The characterization assumes that a percentage of bulbs purchased are not installed until Year 2 and Year 3 (see ISR assumption). The Illinois Technical Advisory Committee has determined the following methodology for calculating the savings of these future installs.

> ***Year 1 (Purchase Year) installs:*** *Characterized using assumptions active in the year current program year (assumptions from the year of purchase/current TRM).*
>
> ***Year 2 and 3 installs:*** *Characterized using delta watts assumption, hours of use and interactive effects from the Install Year i.e. the actual deemed (or evaluated if available) assumptions active in Year 2 and 3 should be applied.*
>
> *The NTG factor from the Purchase Year should be applied.*

Carryover savings for the current program year are derived from second year installations of program measures sold or distributed in the prior program year and third year program measure installations from two years prior to the current program year. For example, CY 2022 carryover savings result from second year installation of CY2021 lighting measures and 3rd year installations of CY2020 lighting measures.

Parameters estimates used to determine the share of carryover lamps installed in the current program year should be taken from the TRM version relevant to the actual purchase year of the carryover lamp. These parameters include in-service rate, leakage, and res/non res splits. All other gross savings parameter estimates should be taken from version of the TRM for year which the program measure was installed. (For claimed carryover in the current program year, this is the current version of the TRM).

3.5 Provisional Measures Savings Assumptions

As defined in the Glossary below, the term Provisional Measures refers to energy-efficient technologies, measures, projects, programs, and/or services that are generally nascent in Illinois or nationally, for which energy savings have not been validated through robust evaluation, measurement and verification (EM&V) efforts, and/or for which there is substantial uncertainty about their cost-effectiveness, performance, and/or customer acceptance. Because, by definition, information on savings for such measures or services is lacking, is based on limited information, or is currently subject to uncertainties, the development of robust assumptions for the TRM challenging. In order to provide calculations for use as the final applicability of these measures is being determined, the TRM can include such measures on a provisional basis, with savings estimates based on the best currently available data or approach, as determined by the IL-TRM Administrator in consultation with the TAC. In such a case, the identifying tag "Provisional Measure" will be added to the TRM measure name. Provisional Measures will be given a one-year Review Deadline, meaning that the measure will undergo a review for reasonableness, continued program relevancy, and update of material assumptions during the following TRM update cycle. The tagging of a measure in the TRM as "Provisional Measure" will ultimately be a TAC decision, and any TRM measure which the TAC determines falls into this category may be assigned.

Expectations are that the Program Administrator will work with evaluators and the TRM Administrator to design and undertake pilot studies, evaluations, or other relevant activities on an appropriate number of installations of the Provisional Measure within that year, with the goal of informing the development of more-robust and Illinois-specific savings assumptions. Including savings estimates in the TRM for such Provisional Measures provides a benchmark to assess effectiveness and allows for tracking and reporting on their value to the programs and customers, even as they are being studied. Savings from any Provisional Measure will be verified by the evaluators as per the characterization included in the TRM for up to 1% of a Program Administrator's portfolio of savings. If savings for any single Provisional Measure rises above 1% of portfolio savings, the additional savings above 1% would be subject to retroactive evaluation risk.

3.6 Glossary

Baseline Efficiency: The assumed standard efficiency of equipment, absent an efficiency program.

Building Types:[24]

Note where a measure installation is within a building or application that does not fit with any of the defined building types below, the user should apply custom assumptions where it is reasonable to estimate them, else the building of best fit should be used.

Building Type	Definition
Assisted Living Multifamily	Applies to residential buildings of three of more units with staff to assist the occupants. Gross Floor Area should include all fully-enclosed space within the exterior walls of the building(s) including individual rooms or units, wellness centers, exam rooms, community rooms, small shops or service areas for residents and visitors (e.g. hair salons, convenience stores), staff offices, lobbies, atriums, cafeterias, kitchens, storage areas, hallways, basements, stairways, corridors between buildings, and elevator shafts.
Auditorium/Assembly	Applies to any performance space such as a theater, arena, or hall. Gross Floor Area should include all space within the building(s), including seating, stage and backstage areas, food service areas, retail areas, rehearsal studios, administrative/office space, mechanical rooms, storage areas, elevator shafts, and stairwells.
Auto Dealership	Applies to facility space used for the retail sale of new or used cars or other vehicles. The total gross floor area should include all supporting functions such as kitchens and break rooms used by staff, storage areas (refrigerated and non-refrigerated), and administrative areas.
Childcare/Pre-school	Applies to any building providing childcare to pre-kindergarten age children.
College/University	Applies to facility space used for higher education. Relevant buildings include administrative headquarters, residence halls, athletic and recreation facilities, laboratories, etc. The total gross floor area should include all supporting functions such as kitchens used by staff, lobbies, atria, conference rooms and auditoria, fitness areas for staff, storage areas, stairways, elevator shafts, etc.
Convenience Store	Applies to facility space used for the retail sale of a limited selection of food and beverage products. The total gross floor area should include all supporting functions such as kitchens and break rooms used by staff, storage areas (refrigerated and non-refrigerated), and administrative areas.
Drug Store	Applies to facility space used for the retail sale of a pharmaceutical products, toiletries, and a limited selection of food and beverage products. The total gross floor area should include all supporting functions such as kitchens and break rooms used by staff, storage areas (refrigerated and non-refrigerated), and administrative areas.
Elementary School	Applies to a school serving children in any grades from Kindergarten through sixth grade.

[24] Source: US EPA, www.energystar.gov, Space Type Definitions, or definitions as developed through the Technical Advisory Committee.

Building Type	Definition
	The total gross floor area should include all supporting functions such as administrative space, conference rooms, kitchens used by staff, lobbies, cafeterias, gymnasiums, auditoria, laboratory classrooms, portable classrooms, greenhouses, stairways, atria, elevator shafts, small landscaping sheds, storage areas, etc.
Emergency Services	Applies to a building representing office, administrative, and functional space for Police/Fire/EMT style buildings. The building borrows many elements from the Low Rise Office definitions for size, envelope, occupant density, etc., but includes expanded occupancy schedules and increased equipment loads.
Exterior	Applies to unconditioned spaces that are outside of the building envelope.
Garage	Applies to unconditioned spaces either attached or detached from the primary building envelope that are not used for living space.
Grocery	Applies to facility space used for the retail sale of food and beverage products. It should not be used by restaurants. The total gross floor area should include all supporting functions such as kitchens and break rooms used by staff, storage areas (refrigerated and non-refrigerated), administrative areas, stairwells, atria, lobbies, etc.
Healthcare Clinic	Applies to a facility space used to provide diagnosis and treatment for medical, dental, or psychiatric outpatient care. Gross Floor Area should include all space within the building(s) including offices, exam rooms, laboratories, lobbies, atriums, conference rooms and auditoriums, employee break rooms and kitchens, rest rooms, elevator shafts, stairways, mechanical rooms, and storage areas.
High School/Middle School	Applies to facility space used as a school building for 7th through 12th grade students. This does not include college or university classroom facilities and laboratories, vocational, technical, or trade schools. The total gross floor area should include all supporting functions such as administrative space, conference rooms, kitchens used by staff, lobbies, cafeterias, gymnasiums, auditoria, laboratory classrooms, portable classrooms, greenhouses, stairways, atria, elevator shafts, small landscaping sheds, storage areas, etc.
Hospital	Applies to a general medical and surgical hospital (including critical access hospitals and children's hospitals) that is either a stand-alone building or a campus of buildings. Spaces more accurately characterized as a Healthcare Clinic should use that definition. The definition of Hospital accounts for all space types that are located within the Hospital building/campus, such as medical offices, administrative offices, and skilled nursing. The total floor area should include the aggregate floor area of all buildings on the campus as well as all supporting functions such as: stairways, connecting corridors between buildings, medical offices, exam rooms, laboratories, lobbies, atria, cafeterias, storage areas, elevator shafts, and any space affiliated with emergency medical care, or diagnostic care.
Hotel/Motel Combined (All Spaces)	Applies to buildings that rent overnight accommodations on a room/suite basis, typically including a bath/shower and other facilities in guest rooms. The total gross floor area should include all interior space, including guestrooms, halls, lobbies, atria, food preparation and restaurant space, conference and banquet space, health clubs/spas, indoor pool areas, and laundry facilities, as well as all space used for supporting functions such as elevator shafts, stairways, mechanical rooms, storage areas, employee break rooms, back-of-house offices, etc. Hotel does not apply to fractional ownership properties such as condominiums or vacation timeshares. Hotel properties should be owned by a single entity and have rooms available on a nightly basis. Where distinction between Hotel and Motel is necessary: Hotel: Room entrances and Corridors are located in the *interior* of the building. Corridors are conditioned spaces. Building can be significantly larger in size/height. Motel: Room entrances and Corridors are located on the *exterior* of the building.

Building Type	Definition
	Corridors are not conditioned spaces. Buildings tend to be two to three stories in height.
Hotel/Motel Common Areas	All the common areas open to guests of the hotel such as the lobby, corridors and stairways, and other spaces that may have continuous or large lighting and HVAC hours.
Hotel/Motel Guest Room	Applies to the guest rooms of the hotel or motel. These spaces are occupied intermittently.
Low-use Small Business	Any business type with low (<3000) operating hours (provided as option in lighting measures).
Manufacturing	Applies to buildings that are dedicated to manufacturing activities. Includes light industry buildings characterized by consumer product and component manufacturing and heavy industry buildings typically characterized by a plant that includes a main production area that has high-ceilings and contains heavy equipment used for assembly line production. These building types may be distinguished by categorizing NAICS (SIC) codes according to the needs of the Program Administrator.
Miscellaneous	Applies to spaces that do not fit clearly within any available categories should be designated as “miscellaneous”.
Mobile Home	A mobile home is a prefabricated structure, built in a factory on a permanently attached chassis before being transported to site. Use single family assumptions throughout the TRM unless otherwise specified.
Movie Theater	Applies to buildings used for public or private film screenings. Gross Floor Area should include all space within the building(s), including seating areas, lobbies, concession stands, bathrooms, administrative/office space, mechanical rooms, storage areas, elevator shafts, and stairwells.
Multifamily-Mid Rise	Applies to residential buildings with up to four floors, including all public and multiuse spaces within the building envelope. Small Multifamily buildings best described as a house should use the residential measure characterizations.
Multifamily-High Rise Combined (All Spaces)	Applies to residential buildings with five or more floors, including all public and multiuse spaces within the building envelope. Gross Floor Area should include all fully-enclosed space within the exterior walls of the building(s) including living space in each unit (including occupied and unoccupied units), interior common areas (e.g. lobbies, offices, community rooms, common kitchens, fitness rooms, indoor pools), hallways, stairwells, elevator shafts, connecting corridors between buildings, storage areas, and mechanical space such as a boiler room. Open air stairwells, breezeways, and other similar areas that are not fully-enclosed should not be included in the Gross Floor Area.
Multifamily-High Rise Common Areas	All the common areas open to occupants of the building such as the lobby, corridors and stairways, and other spaces that may have continuous or high lighting and HVAC hours.
Multifamily-High Rise Residential Units	Applies to the residential units in the building only.
Office-Low Rise	Applies to facility spaces in buildings with four floors or fewer used for general office, professional, and administrative purposes. The total gross floor area should include all supporting functions such as kitchens used by staff, lobbies, atria, conference rooms and auditoria, fitness areas for staff, storage areas, stairways, elevator shafts, etc.
Office-Mid Rise	Applies to facility spaces in buildings with five to nine floors used for general office, professional, and administrative purposes. The total gross floor area should include all supporting functions such as kitchens used by staff, lobbies, atria, conference rooms and auditoria, fitness areas for staff, storage areas, stairways, elevator shafts, etc.
Office-High Rise	Applies to facility spaces in buildings with ten floors or more used for general office, professional, and administrative purposes. The total gross floor area should include all supporting functions such as kitchens used by staff, lobbies, atria, conference rooms and auditoria, fitness areas for staff, storage areas, stairways, elevator shafts, etc.
Religious	Applies to buildings that are used as places of worship. This includes churches, temples,

Building Type	Definition
Worship/Church	mosques, synagogues, meetinghouses, or any other buildings that primarily function as a place of religious worship. Gross Floor Area should include all areas inside the building that includes the primary worship area, including food preparation, community rooms, classrooms, and supporting areas such as restrooms, storage areas, hallways, and elevator shafts.
Restaurant	Applies to a subcategory of Retail/Service space that is used to provide commercial food services to individual customers, and includes kitchen, dining, and common areas.
Retail/Service-Department store	Applies to facility space used to conduct the retail sale of consumer product goods. Stores must be at least 30,000 square feet and have an exterior entrance to the public. The total gross floor area should include all supporting functions such as kitchens and break rooms used by staff, storage areas, administrative areas, elevators, stairwells, etc. Retail segments typically included under this definition are: Department Stores, Discount Stores, Supercenters, Warehouse Clubs, Dollar Stores, Home Center/Hardware Stores, and Apparel/Hard Line Specialty Stores (e.g., books, clothing, office products, toys, home goods, electronics). Retail segments excluded under this definition are: Grocery, Drug Stores, Convenience Stores, Automobile Dealerships, and Restaurants.
Retail/Service- Strip Mall	Applies to facility space used to conduct the retail sale of consumer product goods. Stores must less than 30,000 square feet and have an exterior entrance to the public. The total gross floor area should include all supporting functions such as kitchens and break rooms used by staff, storage areas, administrative areas, elevators, stairwells, etc. Retail segments excluded under this definition are: Grocery, Drug Stores, Convenience Stores, Automobile Dealerships, and Restaurants.
Warehouse	Applies to unrefrigerated or refrigerated buildings that are used to store goods, manufactured products, merchandise or raw materials. The total gross floor area of Refrigerated Warehouses should include all temperature-controlled area designed to store perishable goods or merchandise under refrigeration at temperatures below 50 degrees Fahrenheit. The total gross floor area of Unrefrigerated Warehouses should include space designed to store non-perishable goods and merchandise. Unrefrigerated warehouses also include distribution centers. The total gross floor area of refrigerated and unrefrigerated warehouses should include all supporting functions such as offices, lobbies, stairways, rest rooms, equipment storage areas, elevator shafts, etc. Existing atriums or areas with high ceilings should only include the base floor area that they occupy. The total gross floor area of refrigerated or unrefrigerated warehouse should not include outside loading bays or docks. Self-storage facilities, or facilities that rent individual storage units, are not eligible for a rating using the warehouse model.

Coincidence Factor (CF): Coincidence factors represent the fraction of connected load expected to be coincident with a particular system peak period, on a diversified basis. Coincidence factors are provided for summer peak periods.

Commercial & Industrial: The market sector that includes measures that apply to any of the building types defined in this TRM, which includes multifamily common areas and public housing.[25]

Connected Load: The maximum wattage of the equipment, under normal operating conditions.

Deemed Value: A value that has been assumed to be representative of the average condition of an input parameter.

Default Value: When a measure indicates that an input to a prescriptive saving algorithm may take on a range of values, an average value is also provided in many cases. This value is considered the default input to the algorithm

[25] Measures that apply to the multifamily and public housing building types describe how to handle tenant versus master metered buildings.

and should be used when the other alternatives listed in the measure are not applicable.

End-use Category: A general term used to describe the categories of equipment that provide a service to an individual or building. See Table 2.1 for a list of the end-use categories that are incorporated in this TRM.

Energy Efficiency: "Energy efficiency" means measures that reduce the amount of electricity or natural gas consumed in order to achieve a given end use. "Energy efficiency" includes voltage optimization measures that optimize the voltage at points on the electric distribution voltage system and thereby reduce electricity consumption by electric customers' end use devices. "Energy efficiency" also includes measures that reduce the total Btus of electricity, natural gas and other fuels needed to meet the end use or uses (20 ILCS 3855/1-10). For purposes of this Section, "energy efficiency" means measures that reduce the amount of energy required to achieve a given end use. "Energy efficiency" also includes measures that reduce the total Btus of electricity and natural gas needed to meet the end use or uses (220 ILCS 5/8-104(b)).

Equivalent Full Load Hours (EFLH): The equivalent hours that equipment would need to operate at its peak capacity in order to consume its estimated annual kWh consumption (annual kWh/connected kW) or therms.

High Efficiency: General term for technologies and processes that require less energy, water, or other inputs to operate.

Lifetime: Two important distinctions fall under this definition:

> **Technical Lifetime:** The number of years (or hours) that the new high efficiency equipment is expected to function.
>
> **Measure Lifetime**: The number of years (or hours) that the new high efficiency equipment is expected to provide the savings characterized in the measure. This is the value provided in the "Deemed Lifetime of Efficient Equipment" section of each characterization. The measure lifetime is generally based on the technical lifetime but should represent an estimate of the median number of years that the measures installed under a program are still in place and operable. This may include consideration of the potential for users to remove or remodel and to allow for breakages or imperfect operation, resulting in a shorter measure life. If the savings of a population is expected to *decline* due to issues such as the overriding of settings or poorly maintaining equipment, a midlife adjustment should be used to reduce the lifetime savings;[26] however, the measure lifetime should still reflect the technical lifetime (i.e., the total years any savings are expected to occur). The Measure Lifetime should be used in lifetime savings and cost benefit calculations as well as in Weighted Average Measure Life (WAML) calculations.
>
> Two additional terms used when describing a Measure Lifetime are:
>
> > **Effective Useful Life (EUL)** – EUL is consistent with the Measure Lifetime described above.
> >
> > **Remaining Useful Life (RUL)** – Applies to retrofit or replacement measures. For example, if an existing working refrigerator is replaced with a high efficiency unit, the RUL is an assumption of how many more years the existing unit would have lasted. As a general rule, the RUL is usually assumed to be 1/3 of the EUL.

Load Factor (LF): The fraction of full load (wattage) for which the equipment is typically run.

Measure Cost: The incremental (for time of sale measures) or full cost (both capital and labor for retrofit measures) of implementing the High Efficiency equipment. See Section 3.8 Measure Incremental Cost Definition for full definition.

Measure Description: A detailed description of the technology and the criteria it must meet to be eligible as an energy efficient measure.

Measure: An efficient technology or procedure that results in energy savings as compared to the baseline efficiency.

[26] In rare cases, for example residential Home Energy Report (HER) type programs, in may be appropriate to have savings decay each year throughout the measure life rather than in a midlife adjustment.

Residential: The market sector that includes measures that apply only to detached, residential buildings or duplexes.

Operation and Maintenance (O&M) Cost Adjustments: The dollar impact resulting from differences between baseline and efficient case Operation and Maintenance costs.

Operating Hours (HOURS): The annual hours that equipment is expected to operate.

Provisional Measures: Energy-efficient technologies, measures, projects, programs, and/or services that are generally nascent in Illinois or nationally, for which energy savings have not been validated through robust evaluation, measurement, and verification (EM&V) efforts, and/or for which there is substantial uncertainty about their cost-effectiveness, performance, and/or customer acceptance.

Program: The mode of delivering a particular measure or set of measures to customers. See Section 2.4 for a list of program descriptions that are presently operating in Illinois.

Rating Period Factor (RPF): Percentages for defined times of the year that describe when energy savings will be realized for a specific measure.

Stakeholder Advisory Group (SAG): The Illinois Energy Efficiency Stakeholder Advisory Group (SAG) was first defined in the electric utilities' first energy efficiency Plan Orders to include "… the Utility, DCEO, Staff, the Attorney General, BOMA and CUB and representation from a variety of interests, including residential consumers, business consumers, environmental and energy advocacy organizations, trades and local government... [and] a representative from the ARES (alternative retail electric supplier) community should be included."[27] A group of stakeholders who have an interest in Illinois' energy efficiency programs and who meet regularly to share information and work toward consensus on various energy efficiency issues. The Utilities in Illinois have been directed by the ICC to work with the SAG on the development of a statewide TRM.

3.7 Electrical Loadshapes (kWh)

Loadshapes are an integral part of the measure characterization and are used to divide energy savings into appropriate periods using Rating Period Factors (RPFs) such that each have variable avoided cost values allocated to them for the purpose of estimating cost effectiveness.

For the purposes of assigning energy savings (kWh) periods, the TRM TAC has agreed to use the industry standards for wholesale power market transactions as shown in the following table.

Table 3.2: On- and Off-Peak Energy Definitions

Period Category	Period Definition (Central Prevailing Time)
Winter On-Peak Energy	8AM - 11PM, weekdays, Oct – Apr, No NERC holidays
Winter Off-Peak Energy	All other hours
Summer On-Peak Energy	8AM - 11PM, weekdays, May – Sept, No NERC holidays
Summer Off-Peak Energy	All other hours

Loadshapes have been developed for each end-use by assigning Rating Period Factor percentages to each of the four periods above. Three methodologies were used:

1. Itron eShapes data for Missouri, provided by Ameren and reconciled to Illinois loads, were used to calculate the percentage of load into the four categories above.
2. Where the Itron eShapes data did not provide a particular end-use or specific measure load profile, loadshapes that have been developed over many years by Efficiency Vermont and that have been reviewed by the Vermont Department of Public Service were adjusted to match Illinois period definitions. Note – no weather sensitive loadshapes were based on this method. Any of these load profiles that relate to High Impact Measures should be an area of future evaluation.

[27] ICC Docket No. 07-0540, Final Order at 32-33, February 6, 2008.
http://www.icc.illinois.gov/downloads/public/edocket/215193.pdf

3. Loadshapes have also been developed from primary research studies conducted in Illinois or other jurisdictions if robust datasets were available to support hourly analysis of end use consumption.

The following pages provide the loadshape values for most measures provided in the TRM.[28] The source of the loadshape is also provided.

[28] All loadshape information has been posted to the VEIC SharePoint site and is publicly accessible through the Stakeholder Advisory Group's web site. http://www.ilsag.info/technical-reference-manual.html

3.8 Summer Peak Period Definition (kW)

To estimate the impact that an efficiency measure has on a utility's system peak, the peak itself needs to be defined. Because Illinois currently is a summer peaking state, only the summer peak period is defined for the purpose of this TRM.

Note that Illinois spans two different electrical control areas, the Pennsylvania – Jersey – Maryland (PJM) Interconnection (which includes ComEd), and the Midcontinent Independent System Operator (MISO) (which includes Ameren). As a result, there is some disparity in the actual system peak across the state. However, only PJM has a forward capacity market where an efficiency program can potentially participate. Because ComEd is part of the PJM control area, their definition of the summer peak period is typically used in this TRM to support accurate quantification of demand savings for PJM Forward Capacity Market purposes.

That coincident summer peak period is defined as 1:00-5:00 PM Central Prevailing Time on non-holiday weekdays, June through August.

Summer peak coincidence factors can be found within each measure characterization. The source is provided and is based upon evaluation results, analysis of load shape data, or through a calculation using stated assumptions.

For measures that are not weather-sensitive, the summer peak coincidence factor is estimated whenever possible as the average of savings within the peak period defined above. For weather sensitive measures such as cooling, the summer peak coincidence factor is provided in two different ways. The first method is to estimate demand savings during the utility's peak hour (defined as 3-4pm on June 20th, as provided by Ameren). This is likely to be the most indicative of actual peak benefits. The second way represents the average savings over the summer peak period, consistent with the non-weather sensitive end uses, and is presented so that savings can be bid into PJM's Forward Capacity Market.

3.9 Heating and Cooling Degree-Day Data

Many measures are weather sensitive. Because there is a range of climactic conditions across the state, VEIC engaged the Utilities to provide their preferences for what airports and cities are the best proxies for the weather in their service territories. The result of this engagement is in the table below. All of the data represents 15-year normals from the NCEI National Climactic Data Center (NCDC).[34] Note that the base temperature for the calculation of heating degree-days in this document does not follow the historical 65F degree base temperature convention. Instead VEIC used several different temperatures in this TRM to more accurately reflect the outdoor temperature when a heating or cooling system turns on.

Residential heating is based on 60F, in accordance with regression analysis of heating fuel use and weather by state by the Pacific Northwest National Laboratory.[35] Residential cooling is based on 65F in agreement with a field study in Wisconsin.[36] These are lower than typical thermostat set points because internal gains, such as appliances, lighting, and people, provide some heating. In C&I settings, internal gains are often much higher; the base temperatures for both heating and cooling is 55F.[37] Custom degree-days with building-specific base temperatures are recommended for large C&I projects.

[34] 15-year normals have been used instead of Typical Meteorological Year (TMY) data due to the fact that few of the measures in the TRM are significantly affected by solar insolation, which is one of the primary benefits of using the TMY approach.
[35] Belzer and Cort, Pacific Northwest National Laboratory in "Statistical Analysis of Historical State-Level Residential Energy Consumption Trends," 2004.
[36] Energy Center of Wisconsin, May 2008 metering study; "Central Air Conditioning in Wisconsin, A Compilation of Recent Field Research", p. 32 (amended in 2010).
[37] This value is based upon experience, and it is preferable to use building-specific base temperatures when available.

Table 3.5: Degree-Day Zones and Values by Market Sector

	Residential		C&I			
Zone	HDD	CDD	HDD	CDD	Weather Station / City	Station ID
1	5,230	877	4,171	2,284	Rockford AP / Rockford	USW00094822
2	4,798	1,047	3,760	2,494	Chicago O'Hare AP / Chicago	USW00094846
3	4,266	1,183	3,296	2,761	Springfield #2 / Springfield	USC00118186
4	3,188	1,641	2,351	3,480	Belleville SIU RSCH / Belleville	USW00013802
5	3,390	1,450	2,499	3,186	Carbondale Southern IL AP / Marion	USW00093810
Average	4,631	1,098	3,619	2,596	Weighted by occupied housing units	
Base	60F	65F	55F	55F	15 year climate normals, 2006-2020	

The above assumptions based on 15-year climate normals are appropriate for use where annual consumption values are being estimated. For any peak load calculations, consideration of climate extremes or where hourly climate variations are modeled, the TAC agreed to utilize TMYx data (2007-2021) to develop variable assumptions. The specific TMYx files that are utilized is provided below:

Zone 1: USA_IL_Rockford-Chicago.Rockford.Intl.AP.725430_TMYx.2007-2021
Zone 2: USA_IL_Chicago.OHare.Intl.AP.725300_TMYx.2007-2021
Zone 3: USA_IL_Springfield-Lincoln.Capital.AP.724390_TMYx.2007-2021
Zone 4: USA_IL_Belleville.AP.724338_TMYx.2007-2021
Zone 5: USA_IL_Marion-Williamson.County.Rgnl.AP.724339_TMYx.2007-2021

This table assigns each of the proxy cities to one of five climate zones. The following graphics from the Illinois State Water Survey show isobars (lines of equal degree-days), and we have color-coded the counties in each of these graphics using those isobars as a dividing line. Using this approach, the state divides into five cooling degree-day zones and five heating degree-day zones. Note that although the heating and cooling degree-day maps are similar, they are not the same, and the result is that there is a total of 10 climate zones in the state. The counties are listed in the tables following the figures for ease of reference. In addition, an Excel file containing all Illinois Zip Codes with the corresponding Heating and Cooling Degree-day zones is provided on the SharePoint site within the 'TRM Reference Documents' section.

3.10 Measure Incremental Cost Definition

Operations and Maintenance (O&M) and/or Deferred Baseline Replacement Cost Changes: Any avoided costs are treated as benefits, and any increased costs are treated as Incremental Costs. In cases where the efficient Measure has a significantly shorter or longer life than the relevant baseline measure (e.g., LEDs versus halogens), the avoided baseline replacement measure costs should be accounted for as a benefit in the TRC test analysis.

Incremental Costs means the difference between the cost of the efficient Measure and the cost of the most relevant baseline measure that would have been installed (if any) in the absence of the efficiency program. Installation costs (material and labor) shall be included if there is a difference between the efficient Measure and the baseline measure. The Customer's value of service lost, the Customer's value of their lost amenity, and the Customer's transaction costs shall be included in the TRC test analysis where a reasonable estimate or proxy of such costs can be easily obtained (e.g., Program Administrator payment to a Customer to reduce load during a demand response event, Program Administrator payment to a Customer as an inducement to give up functioning equipment). This Incremental Cost input in the TRC analysis is not reduced by the amount of any Incentives (any Financial Incentives Paid to Customers or Incentives Paid to Third Parties by a Program Administrator that is intended to reduce the price of the efficient Measure to the Customer). Incremental Cost calculations will vary depending on the type of efficient Measure being implemented, as outlined in the examples provided below and as set forth in the IL-TRM. Note that the TRM includes at least one deemed incremental cost(s) as a default value(s) for most measures. However, consistent with the TRM Policy Document policy, in instances where Program Administrators have better information on the true incremental cost of the measures (e.g., direct install programs), the Program Administrator-specific incremental cost value should be used for the purposes of cost-effectiveness analysis.

Examples of Incremental Cost calculations include:

a. The Incremental Cost for an efficient Measure that is installed in new construction or is being purchased at the time of natural installation, investment, or replacement is the additional cost incurred to purchase an efficient Measure over and above the cost of the baseline/standard (i.e., less efficient) measure (including any incremental installation, replacement, or O&M costs if those differ between the efficient Measure and baseline measure).

b. For a retrofit Measure where the efficiency Program caused the Customer to update their existing equipment, facility, or processes (e.g., air sealing, insulation, tank wrap, controls), where the Customer would not have otherwise made a purchase, the appropriate baseline is zero expenditure, and the Incremental Cost is the full cost of the new retrofit Measure (including installation costs).

c. For the early replacement of functioning equipment with a new efficient Measure, where the Customer would not have otherwise made a purchase for a number of years, the appropriate baseline is a dual baseline that begins as the existing equipment and shifts to the new standard equipment after the expected remaining useful life of the existing equipment ends. Thus, the Incremental Cost is the full cost of the new

efficient Measure (including installation costs) being purchased to replace a still-functioning equipment less the present value of the assumed deferred replacement cost (including installation costs) of replacing the existing equipment with a new baseline measure at the end of the existing equipment's life. This deferred credit may not be necessary when the lifetime of the measure is short, the costs are very low, the measure is highly cost-effective even without the deferred credit, or for other reasons (e.g., certain Direct Install Measures, Measures provided in Kits to Customers).[38]

d. For study-based services (e.g., facility energy audits, energy surveys, energy assessments, retro-commissioning, new construction design services), the Incremental Cost is the full cost of the study-based service. Even if the study-based service is performed entirely by a Program Administrator's program implementation contractor, the full cost of the study-based service charged by the program implementation contractor is the Incremental Cost, because this is assumed to be the cost of the study-based service that would have been incurred by the Customer if the Customer were to have the study-based service performed in the absence of the efficiency Program. If the Customer implements efficient Measures as a result of the study-based service provided by the efficiency Program, the Incremental Cost for those efficient Measures should also be classified as Incremental Costs in the TRC analysis. Note that the Incremental Costs associated with study-based services should be included in Cost-Effectiveness calculations "only at the level at which they become variable."[39] In some cases, this will be at the Measure level; in others, it will be at the Program level. Such costs should be included in Measure-level Cost-Effectiveness calculations only when they are inseparable from the efficiency improvements – i.e., when the provision of the study-based service is what produces energy savings (e.g., retro-commissioning). Conversely, when study-based service costs are separable from the costs of the efficient Measures themselves and Customer, Program Administrator and/or other parties have discretion over which of the identified efficient Measures to subsequently install (e.g., for facility energy audits, surveys or assessments that are used to identify potential efficient Measures for installation), the Incremental Cost associated with such study-based services should be included only in Program-level Cost-Effectiveness analyses (rather than allocated to individual efficient Measures).

e. For the early retirement of functioning equipment before its expected life is over (e.g., appliance recycling Programs), the Incremental Costs are composed of the Customer's value placed on their lost amenity, any Customer transaction costs, and the pickup and recycling cost. The Incremental Costs include the actual cost of the pickup and recycling of the equipment (often paid for by a Program Administrator to a program implementation contractor) because this is assumed to be the cost of recycling the equipment that would have been incurred by the Customer if the Customer were to recycle the equipment on their own in the absence of the efficiency Program. The payment a Program Administrator makes to the Customer serves as a proxy for the value the Customer places on their lost amenity and any Customer transaction costs.

3.11 Discount Rates, Inflation Rates, and O&M Costs

The Illinois Utilities use screening tools that apply an appropriate discount rate to any future costs or benefits. From 2026 to 2029, the societal discount rate, required for use by all electric utilities, is defined as a nominal discount rate of 4.33%, or a real (inflation-adjusted) discount rate of 2.0%.[40]

Where a future cost is provided within the TRM (e.g., in early replacement measures where a deferred baseline replacement cost is provided) and the future cost has been adjusted using an inflation rate of 2.28% (based on USEIA/AEO Inflation Forecast), the nominal discount rate should be used to discount to the present value. Where future costs have not been adjusted for inflation, the real discount rate should be used to discount to present value.

[38] In such instances, the Incremental Cost is the full cost of direct installation Measures (materials and labor) and the full cost of Measures provided in Kits to Customers.

[39] See The National Efficiency Screening Project, National Standard Practice Manual for Assessing Cost-Effectiveness of Energy Efficiency Resources, Edition 1, Spring 2017. Retrieved from https://nationalefficiencyscreening.org/national-standard-practice-manual/.

[40] Real discount rate is based on EPA's Social Cost of Carbon Report and Inflation Rate on USEIA/AEO Inflation Forecast. Nominal discount rate is calculated as ((1+Inflation) * (1+RDR) – 1).

The following table provides the historical discount rate that have been applied:

Program Year Applied To (TRM Based Upon)	Nominal Discount Rate	Real Discount Rate	Inflation Rate
2026 – 2029 (v14.0 – v17.0)	4.33%	2.0%[41] (EPA's Social Cost of Carbon Report)	2.28% (USEIA/AEO Inflation Forecast)
2022 – 2025 (v10.0 – v13.0)[42]	2.40%	0.42% (10yr Treasury bond rates)	1.98%
2018 – 2021 (v6.0 – v9.0)[43]	2.38%	0.46% (10yr Treasury bond rates)	1.91%
EPY9 and GPY6 (v5.0)	Not specified	5.34% (WACC)	1.91%
EPY5-8 and GPY1-5 (v1.0 - v4.0)	Not specified	5.23% (WACC)	Not specified

As per 'Section 8.5 Discount Rates' of the Illinois Energy Efficiency Policy Manual, new discount and inflation rates for subsequent Plan cycles will be added to the IL-TRM as soon as available, and no later than October 1 of the year prior to the Plan filing.

Some measures specify an operations and maintenance (O&M) parameter that describes the incremental O&M cost savings that can be expected over the measure's lifetime. For most measures the TRM does not specify the NPV of the O&M costs. Instead, the necessary information required to calculate the NPV is included. An example is provided below:

Baseline Case:	O&M costs equal $150 every two years.
Efficient Case:	O&M costs equal $50 every five years.

Given this information, the incremental O&M costs can be determined by discounting the cash flows in the Baseline Case and the Efficient Case separately using the real discount rate.

For a select few measures that include baseline shifts that result in multiple component costs and lifetimes over the lifetime of the measure, this standard method cannot be used. In only these cases, the O&M costs are presented both as Annual Levelized equivalent cost (i.e., the annual payment that results in an equivalent NPV to the actual stream of O&M costs) and as NPVs using a real societal discount rate of 2.0%.

When discounting nominal data that was adjusted to nominal from original real data using an inflation rate that is different than the IL-TRM inflation rate value, the analyst should first adjust for inflation using the original (non-IL-TRM) value to convert the data back to the appropriate year's real dollars and then use the real discount rate as specified in the IL-TRM.

[41] All parties agree that reasonable arguments can be made to support use of either a 1.5% or 2.0% real discount rate. All parties agree to use 2.0% as a compromise value in order to avoid litigation on this issue in the EEP proceedings. All parties reserve the right to advocate for different discount rates in other analyses or proceedings before the Commerce Commission, including in future efficiency planning or reconciliation cases. No party shall use the fact that a party has agreed to this compromise position as evidence in a future proceeding concerning discount rate assumptions.

[42] Consistent with the IL EE Policy Manual Version 2.0, the societal discount rate used for analyses pertaining to the 2022-2025 Plan cycle will be this discount rate first presented in the 2021 IL-TRMv9.0. "The societal discount rate will be fixed for the entirety of each Plan period, and used for all analyses pertaining to that Plan period. That is, the real and/or nominal societal discount rates used in the development of the Program Administrators' multi-year Plans shall also be used for retrospective Cost-Effectiveness analyses of the evaluated results of each of the years in those Plans as well as in the IL-TRM applicable to the years in those Plans."

[43] Consistent with the IL EE Policy Manual Version 2.0, "The societal discount rate used for analyses pertaining to the 2018-2021 Plan cycle will be the discount rate in the 2019 IL-TRM."

3.12 Interactive Effects

The TRM presents engineering equations for most measures. This approach is desirable because it conveys information clearly and transparently and is widely accepted in the industry. Unlike simulation model results, engineering equations also provide flexibility and the opportunity for users to substitute local, specific information for specific input values. Furthermore, the parameters can be changed in TRM updates to be applied in future years as better information becomes available.

One limitation is that some interactive effects between measures are not automatically captured. Because we cannot know what measures will be implemented at the same time with the same customer, we cannot always capture the interactions between multiple measures within individual measure characterizations. However, interactive effects with different end-uses are included in individual measure characterizations whenever possible. For instance, waste heat factors are included in the lighting characterizations to capture the interaction between more-efficient lighting measures and the amount of heating and/or cooling that is subsequently needed in the building. By contrast, no effort is made to account for interactive effects between an efficient air conditioning measure and an efficient lighting measure, because it is impossible to know the specifics of the other measure in advance of its installation.

For custom measures and projects where a bundle of measures is being implemented at the same time, these kinds of interactive effects should be estimated. Interactive effects between measures should be captured sequentially in accordance with best practice with respect to building science. For example: when building HVAC and envelope improvements are made at the same time, envelope improvement savings should be calculated first using the existing HVAC in the calculation, and the HVAC improvement savings should be calculated second assuming that the envelope improvements have already been made and the new installed HVAC capacity reflects the lower heating and cooling loads.

3.13 Electrification and Fossil Fuel Baselines (Public Act 102-0662)

On September 15, 2021, the Climate and Equitable Jobs Act (CEJA) was signed into law, effective immediately. Section 220 ILCS 5/8-103B(b-27) of CEJA states that beginning in 2022 an electric utility may:

> *"...offer and promote measures that electrify space heating, water heating, cooling, drying, cooking, industrial processes, and other building and industrial end uses that would otherwise be served by combustion of fossil fuel at the premises, provided that the electrification measures reduce total energy consumption at the premises. The electric utility may count the reduction in energy consumption at the premises toward achievement of its annual savings goals. The reduction in energy consumption at the premises shall be calculated as the difference between: (A) the reduction in Btu consumption of fossil fuels as a result of electrification, converted to kilowatt-hour equivalents by dividing by 3,412 Btu's per kilowatt hour; and (B) the increase in kilowatt hours of electricity consumption resulting from the displacement of fossil fuel consumption as a result of electrification measures under this subsection".*

3.13.1 Fossil Fuel Baseline Efficiencies for Electric Efficiency Measures

The energy savings for an electric efficiency measure with a fossil fuel baseline is the difference in energy consumption between the fossil fuel baseline and the efficient electric measure.

Use the following approach to define the baseline for efficient electric measures that would otherwise be served by combustion of fossil fuel at the premise:

1. If available, apply the baseline efficiency assumptions included in the TRM.

2. If not available, apply the following assumptions:

a. For Time of Sale and New Construction applications, apply the minimum efficiency available in Illinois on the new equipment market for the fossil fuel.
b. For Early Replacement:
    i. If the existing system is known:
        1. For the remaining life of the existing equipment, use the rated efficiency of the existing system.
        2. For the remaining measure life after the existing equipment would have been replaced, use the minimum efficiency available in Illinois on the new equipment market for the fossil fuel.
    ii. If the existing system is unknown:
        1. Use the best available information for existing equipment efficiency. If no information is available, use the minimum efficiency available in Illinois on the new equipment market for the fossil fuel.

Where a measure includes both fuel switch savings and non-fuel switch savings, the characterization will clearly separate the two types to allow appropriate tracking. In addition, a separate section entitled 'Cost Effectiveness Screening' is provided in all fuel switch measures to outline the actual meter level impacts of a fuel switch measure for use in cost effectiveness screening calculations. An example fuel switch calculation is provided below (from 5.1.10 ENERGY STAR Clothes Dryer):

An ENERGYSTAR Most Efficient Heat Pump clothes dryer with $CEFeff_{Elec}$ of 5.7 purchased in place of a baseline gas dryer:

SiteEnergySavings (MMBTUs) = [FuelSwitchSavings] + [NonFuelSwitchSavings]

FuelSwitchSavings = $[(Load/CEFbase_{Gas} * Ncycles * MMBtu_convert * \%Gas_{Gas}] - [Load/CEFeff_{Elec} * Ncycles * \%Gas_{Gas} * 3412/1{,}000{,}000]$

= (8.45/2.84 * 283 * 0.003412 * 0.84) - (8.45/5.7 * 283 * 0.84 * 3412/1000000)

= 1.21 MMBtu

NonFuelSwitchSavings = $[(Load/CEFbase_{Gas} * Ncycles * MMBtu_convert * \%Electric_{Gas}] - [Load/CEFeff_{Elec} * Ncycles * \%Electric_{Gas} * 3412/1{,}000{,}000]$

= (8.45/2.84 * 283 * 0.003412 * 0.16) - (8.45/5.7 * 283 * 0.16 * 3412/1000000)

= 0.23 MMBtu

SiteEnergySavings (MMBTUs) = 1.21 + 0.23

= 1.44 MMbtu

If supported by an electric utility: ΔkWh = ΔSiteEnergySavings * 1,000,000 / 3,412

= 1.44 * 1,000,000/3412

= 422.5 kWh

Actual meter impacts are as follows (calculation methodology is provided in the Cost Effectiveness Screening section at the end of each measure with fuel switching scenarios):

ΔTherms = [Gas Dryer Consumption Replaced]

= $[(Load/CEFbase_{Gas} * Ncycles * Therm_convert * \%Gas_{Gas}]$

= [8.45/2.84 * 283 * 0.03412 * 0.84]

= 24.1 therms

ΔkWh = [Gas Dryer Electric Consumption Replaced] - [Electric Dryer Consumption Added]

= $[Load/CEFeff_{Gas} * Ncycles * \%Electric_{Gas}] – [Load/CEFeff_{Elec} * Ncycles * \%Electric_{Electric}]$

= [8.45/2.84 * 283 * 0.16] – [8.45/5.7 * 283 * 1]

= - 284.8 kWh

3.13.2 Fuel Units and Conversion Factors

Savings presented in the "Fossil Fuel Savings" section of the TRM will always be provided in Therms. Conversion to other fuel units should be based on site energy use, utilizing the conversion factors displayed below:

Fuel	Energy Units	BTUs per Energy Unit	Conversion Multiplier from Therms to Energy Unit
Natural Gas	Therms	100,000	1.0

Fuel	Energy Units	BTUs per Energy Unit	Conversion Multiplier from Therms to Energy Unit
Propane Gas	Gallons	91,333	1.095
Fuel Oil	Gallons	138,500	0.722
Diesel	Gallons	138,500	0.722
Electric	kWh	3,412	29.3

3.14 Secondary kWh Savings from Fossil Fuel Saving Measures

Up until v10, only natural gas savings were detailed within the measure characterizations. A number of measures provide secondary electric savings due to the reduction in heating consumption (for example furnace fan savings resulting from shell improvements in a fossil fuel heated home, typically labelled as kWh_heating Gas). These secondary savings can be claimed regardless of the fossil fuel in question (e.g. shell improvements to a home with oil heat) even if natural gas is specifically mentioned within the characterization.

2026 Illinois Statewide Technical Reference Manual for Energy Efficiency

Version 14.0

Volume 2: Commercial and Industrial Measures

FINAL

September 19, 2025

Volume 3: Residential Measures

Volume 4: Cross Cutting Measures and Attachments

4 Volume 2: Commercial and Industrial Measures

4.1. Agricultural End Use

4.1.1 Engine Block Timer for Agricultural Equipment

DESCRIPTION

The measure is a plug-in timer that is activated below a specific outdoor temperature to control an engine block heater in agricultural equipment. Engine block heaters are typically used during cold weather to pre-warm an engine prior to start, for convenience, heaters are typically plugged in considerably longer than necessary to improve startup performance. A timer allows a user to preset the heater to come on for only the amount of time necessary to pre-warm the engine block, reducing unnecessary run time even if the baseline equipment has an engine block temperature sensor.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient measure is an engine block heater operated by an outdoor plug-in timer (15 amp or greater) that turns on the heater only when the outdoor temperature is below 25 °F.

DEFINITION OF BASELINE EQUIPMENT

The baseline scenario is an engine block heater that is manually plugged in by the farmer to facilitate equipment startup at a later time.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life if assumed to be 3 years.[1]

DEEMED MEASURE COST

The incremental cost per installed plug-in timer is $150[2] plus $50 in labor for direct install of wall – and engine-mounted devices, if applicable. No labor cost should be added for the installation of Power Badger (extension cord) devices.[3]

COINCIDENCE FACTOR

Engine block timers only operate in the winter, so the summer peak demand savings is zero.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = ISR * Use\ Season * \%_{Days} * HrSave/Day * kW_{heater} - ParaLd$$

Where:

ISR = In Service Rate

[1] Equipment life is expected to be longer, but measure life is more conservative to account for possible attrition in use over time.

[2] Estimate based on current market research completed by ICF. Rocky Mountain Power implementers indicated that direct installs are primarily Power Badger (extension cord) installs, which range from $150 to $155.

[3] Based on current market research completed by ICF

= 78.39%[4]

Use Season = The number of days in the use season in which the temperature drops below 25°F in the state of Illinois[5]

Climate Zone (City based upon)	Use Season
1 (Rockford)	79
2 (Chicago)	68
3 (Springfield)	53
4 (Belleville)	45
5 (Marion/Murphysboro)	27
State-Wide Average	**54**

%Days = Proportion of days timer is used with the Use Season

= 84.23%[6]

HrSave/Day = Hours of savings per day when timer is used

= 7.765 hours per day[7]

kW_{heater} = Connected load of the engine block heater

= 1.5 kW[8]

ParaLd = Parasitic load

= 5.46 kWh[9]

For example, using the default assumptions on the installation of a timer on an engine block with a 1.5 kW heater:

ΔkWh = 78.39% * 54 days * 84.23% * 7.765 Hr/Day * 1.5 kW - 5.46 kWh

= 409.8 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

MEASURE CODE: CI-AGE-EBLT-V04-260101

REVIEW DEADLINE: 1/1/2029

4.1.2 High Volume Low Speed Fans

DESCRIPTION

The measure applies to horizontally mounted ceiling high volume low speed (HVLS) fans that are replacing multiple non HVLS fans that have reached the end of useful life in agricultural applications.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment must be a fan with a diameter above 16 feet that meets program minimum efficiency requirements.

DEFINITION OF BASELINE EQUIPMENT

As a retrofit measure, the actual existing conditions are taken as baseline. The number and wattage of the existing fans shall be used to define baseline energy consumption. As a time of sale measure, baseline is taken as the total operating wattage of conventional fans required to match the flow rate (CFM) rating of the efficient equipment.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[10]

DEEMED MEASURE COST

As a retrofit measure, the actual installation cost should be used for screening and reporting purposes.

For a time of sale measure, actual full installed costs may be used along with the following baseline cost assumptions:[11]

Diameter of Fan (feet)	Baseline Cost
16-17.9	$1210
18-19.9	$1460
20-23.9	$1840
24 +	$2090

If actual costs are unavailable for time of sale, the incremental measure costs are as follows:[12]

Diameter of Fan (feet)	Incremental Cost
16-17.9	$4100
18-19.9	$4130
20-23.9	$4190
24 +	$4230

LOADSHAPE

Loadshape C34 - Industrial Motor

[10] Average motor life is calculated by dividing the estimated motor life (35,000 hours) divided by the annual run hours, taken to be the unknown/other farm commodity type of 3,259 hours (see description of default run hours on following page); and rounded down to nearest whole year. Motor life source, U.S. Department of Energy Advanced Manufacturing Office, Motor Systems Tip Sheet #3.

[11] Baseline full installed costs linearly extrapolated using cost data from the Illinois ActOnEnergy TRM No. 2010-4. Midpoints were used to establish a single cost for each fan diameter category. Costs rounded up to the nearest $10.

[12] Incremental costs linearly extrapolated using cost data from the Illinois ActOnEnergy TRM No. 2010-4. Midpoints were used to establish a single cost for each fan diameter category. Costs rounded up to the nearest $10.

COINCIDENCE FACTOR

The measure has deemed kW savings therefore, a coincidence factor is not applied.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{\sum(N_{base} * Watts_{base}) - \sum(N_{ee} * Watts_{ee})}{1000} * Hours$$

Where:

N_{base} = Number of baseline (conventional) fans being replaced (of equivalent wattage)

= Actual (for Retrofit projects). For time of sale projects, the number of baseline fans should be set equivalent to the number of HVLS fans being installed.

$Watts_{base}$ = Operating demand (W) of baseline fan

=Actual (Retrofit). For time of sale projects refer to the time of sale HVLS connected load savings table below.

N_{ee} = Number of efficient fans installed (of equivalent wattage)

= Actual

$Watts_{ee}$ = Operating demand (W) of efficient fan

= Actual (Retrofit). For time of sale projects refer to the Time of Sale HVLS connected load savings table below.

Time of Sale HVLS Connected Load Savings[13]

Diameter of Fan (feet)	Watts_base	Watts_ee
16-17.9	4497	761
18-19.9	5026	850
20-23.9	5555	940
24 +	6613	1119

Hours = Actual hours of operation. If unknown use the assumptions from the table below[14]

Facility Type	Annual Hours of Operation
Hog	3,458
Poultry	2,790
Dairy	2,455
Unknown/Other	3,133

[13] KEMA 2009 Evaluation of IPL Energy Efficiency Programs, Appendix F, Group 1 Programs, Volume 2 (Table 17). Typically, the number of baseline conventional circulation fans the HVLS fan is off-setting is not a one for one replacement scenario. Due to their more efficient design, a single HVLS fan can move and displace as much air as multiple conventional circulation fans. The baseline wattage represents the equivalent quantity of baseline fans and their wattages to match that of a single HVLS fan.

[14] Based on NCEI/NCDC US Hourly Climate Normals data for Weather Stations in each Climate Zone, and weighted by 2010 US Census Data. The unknown/other commodity type is a weighted average of hog, poultry, and dairy facilities based on farm count as sourced from the U.S. 2017 Agriculture Census for Iowa. Dairy Farm Energy Management Guide, Southern California Edison February, 2004. The guide recommends controlling fans in order to provide maximum ventilation as necessary at 72°F and above due to heat stress concerns on cows at and above that temperature. The 67°F balance point was developed assuming a 5°F temperature band, assuming the interior temperature of the barn will be greater than that outside due to internal heat gains.

Based on default assumptions above, deemed savings for replacing one fan would be:

Facility Type	Diameter of Fan (feet)	ΔkWh
Hog	16-17.9	12,919.1
	18-19.9	14,440.6
	20-23.9	15,958.7
	24 +	18,998.3
Poultry	16-17.9	10,423.4
	18-19.9	11,651.0
	20-23.9	12,875.9
	24 +	15,328.3
Dairy	16-17.9	9,171.9
	18-19.9	10,252.1
	20-23.9	11,329.8
	24 +	13,487.8
Unknown/Other	16-17.9	11,704.9
	18-19.9	13,083.4
	20-23.9	14,458.8
	24 +	17,212.7

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\sum(\text{-}N_{base} * Watts_{base}) - \sum(N_{ee} * Watts_{ee})}{1000} * CF$$

Where:

CF = Summer Peak Coincidence Factor

= 100%[15]

Based on default assumptions above, deemed savings would be:

Facility Type	Diameter of Fan (feet)	ΔkW
Hog	16-17.9	3.74
	18-19.9	4.18
	20-23.9	4.62
	24 +	5.49
Poultry	16-17.9	3.74
	18-19.9	4.18
	20-23.9	4.62
	24 +	5.49
Dairy	16-17.9	3.74
	18-19.9	4.18
	20-23.9	4.62
	24 +	5.49
Unknown/Other	16-17.9	3.74
	18-19.9	4.18

[15] Industrial Ventilation CF from eQuest.

Facility Type	Diameter of Fan (feet)	ΔkW
	20-23.9	4.62
	24 +	5.49

REVIEW DEADLINE: 1/1/2028

4.1.3 High Speed Fans

DESCRIPTION

The measure applies to high speed exhaust, ventilation and circulation fans that are replacing an existing unit that reached the end of its useful life in agricultural applications.

Agricultural circulation fans are fans located in barns to provide air movement that helps to keep animals cool. Circulation fan efficiency is expressed as CFM[16]/watt and is derived from the thrust efficiency ratio (TER) in pounds force per watt (lbf/W).

Agricultural ventilation fans provide ventilation air to keep animals cool. Fan efficiency is expressed as CFM/watt and is derived from the thrust efficiency ratio (TER) in pounds force per watt (lbf/kW).

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment must be certified by BESS Labs[17] with fan diameters above 12 inches that meet program minimum efficiency requirements.

Diameter of Fan (inches)	Circulation Fans IPL Minimum Efficiency (CFM/Watt)	Ventilation Fans IPL Minimum Efficiency (CFM/Watt) at (0.05 SP[18])
12-23	10.7	10.1
24-35	11.5	13.5
36-47	19.0	17.4
48+	21.5	20.3

Efficient fans are assumed to be governed by thermostatic on/off controls.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline condition is assumed to be an existing fan that reached the end of its useful life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years for Circulation Fans[19] and 7 years for Ventilation Fans[20] .

DEEMED MEASURE COST

Actual full installed costs may be used along with the following baseline cost assumptions:[21]

[16] Cubic Feet per Minute
[17] University of Illinois, Department of Agricultural and Biological Engineering. http://bess.illinois.edu/
[18] Static Pressure in units of inches of water
[19] Average motor life is calculated by dividing the estimated motor life (35,000 hours) divided by the annual run hours, taken to be the unknown/other farm commodity type of 3,259 hours (see description of default run hours on following page); and rounded down to nearest whole year. Motor life source, U.S. Department of Energy Advanced Manufacturing Office, Motor Systems Tip Sheet #3.
[20] Average motor life is calculated by dividing the estimated motor life (35,000 hours) divided by the annual run hours, taken to be the unknown/other farm commodity type of 4,800 hours (see description of default run hours on following page); and rounded down to nearest whole year. Motor life source, U.S. Department of Energy Advanced Manufacturing Office, Motor Systems Tip Sheet #3.
[21] Baseline full installed costs from Act on Energy Commercial Technical Reference Manual No. 2010-4. Cost for 12-23" diameter fans determined through extrapolation of costs for other fan sizes.

Diameter of Fan (inches)	Baseline Cost
12-23	$375
24-35	$450
36-47	$525
48+	$600

If actual cost not available, assume an incremental total installed cost of $150.[22]

LOADSHAPE

4.1.4 Livestock Waterer

DESCRIPTION

This measure applies to the replacement of electric open waterers with sinking or floating water heaters with equivalent herd size watering capacity of the old unit. Livestock waterers utilize electric heating elements and are used in cold climate locations in order to prevent water from freezing. Energy efficient livestock waterers, also called no or low energy livestock waterers, are closed and insulated watering containers that use lower wattage heating elements, thermostatically controlled, and water agitation (either in the form of air bubbles or floating balls), to prevent water from freezing, using less energy.

This measure was developed to be applicable to the following program types: RF, TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to an electrically heated thermally insulated waterer with minimum 2 inches of insulation. A thermostat is required on unit with heating element greater than or equal to 250 watts.[27]

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline equipment is assumed to be an electric open waterer with sinking or floating water heaters that have reached the end of useful life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[28]

DEEMED MEASURE COST

For time of sale, the incremental cost is $575[29]. For retrofit, use actual costs.

LOADSHAPE

Loadshape C04 - Non-Residential Electric Heating

COINCIDENCE FACTOR

Heated livestock waterers only operate in the winter in order to keep water from freezing so the summer peak coincident demand savings is zero.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{(WattsBASE - WattsEE)}{1{,}000} * Hours$$

Where:

WattsBASE = Power consumption of baseline equipment. Actual, if known

= If unknown, use 1,100 for RF, 500 for TOS[30]

[27] Act on Energy Commercial Technical Reference Manual No. 2010-4

[28] PA Consulting Group Inc. "State of Wisconsin Public Service Commission of Wisconsin Focus on Energy Evaluation Business Programs: Measure Life Study Final Report." August 25, 2009

[29] Internet research of leading distributers

[30] EnSave, Energy Efficient Stock Waterers

WattsEE = Power consumption of efficient equipment. Actual, if known

= If unknown, use 250 for energy-efficient, 0 for energy free

1,000 = Kilowatt conversion factor

Hours = Average annual run hours of heater. Actual if known.

= If unknown, use the table below[31]

Climate Zone (City based upon)	Hours
1 (Rockford)	2,321
2 (Chicago)	2,103
3 (Springfield)	1,731
4 (Belleville)	1,362
5 (Marion/Murphysboro)	1,016
State-Wide Average	**1,707**

Based on default assumptions above, deemed savings would be:

Measure Type	Efficient Option	ΔkWh
Retrofit	Energy Efficient	1,451.0
	Energy Free	1,877.7
Time of Sale	Energy Efficient	426.8
	Energy Free	853.5

[31] The number of days in the use season in which the temperature drops below 35°F in the state of Illinois. The data is sourced as an average from TMYx weather data for five different weather zones within the state, see 'Ag Op Hours_2023 – IL- Final.xlsx

4.1.5 Fan Thermostat Controller

DESCRIPTION

Incorporating a ventilation fan thermostat controller can reduce energy consumed where livestock is housed. Livestock ventilation fans reduce heat stress during the warmer months of the year.

For the purposes of this measure characterization, the installed ventilation fan thermostat controllers are temperature based on/off controls. While the complexity and intelligence of available controls can vary widely, where integrated controls can automate multiple modes and stages of ventilation, this measure assumes the control functionality is turning off the fan once the temperature falls to a certain point. It is recommended that other intelligent control technologies and strategies be handled through a custom approach, as these control installations require commissioning to optimize the functionality based on unique site and design considerations.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure applies to the incorporation of thermostatic controller for ventilation fans used in the livestock industry. To qualify, the ventilation fan must be used to modulate the temperature to reduce heat stress in a livestock facility.

DEFINITION OF BASELINE EQUIPMENT

The baseline for this measure is a non-thermostatically controlled livestock ventilation fan that operates constantly in their maximum capacity.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life expectancy of this measure is 15 years.[32]

DEEMED MEASURE COST

The incremental cost is estimated at $50 per fan.[33]

LOADSHAPE

Loadshape C34 – Industrial Motor

COINCIDENCE FACTOR

The savings come from a reduction in nighttime operation, so a coincidence factor is not applicable for this measure.

Algorithm

CALCULATION OF ENERGY SAVINGS

The annual energy savings are generated by the fan being disabled at temperatures below 70°F. Typically the evening hours are cooler, and the ventilation fans are not required at these lower temperatures. It is assumed, prior to retrofit, that baseline ventilation fans are operating continuously from May 1st through October 31st, encapsulating the entire portion of the year in which hot temperatures exist and the need for livestock housing ventilation is prevalent. The efficient fan operation is derived from regional TMYx data for the state of Illinois and represent, over the same timeline that was used for the baseline, the number of hours in which the temperature is above 70°F. Electric Energy Savings

[32] Focus on Energy Evaluation Business Programs Measure Life Study: Final Report August 25, 2009, Public Service Commission of Wisconsin.

[33] The measure incremental cost is sourced from the 2023 Michigan Energy Measures Database (MEMD).

$$\Delta kWh = HP_{Fan} \times LF \times C_{ME} \times \Delta Hours \div Eff_{motor}$$

Where:

HP_{Fan} = Motor horsepower of the controlled fan

= Actual; if unknown, default to 1 horsepower[34]

LF = Fan load factor

= 0.75

CME = 0.746 kW to HP conversion factor

ΔHours = Reduction in fan run hours as a result of the thermostat controller, dependent on location[35]

Zone	$Hours_{Base}$	$Hours_{Eff}$	ΔHours
Hog	6,307	4,773	1,534
Poultry	5,670	5,298	372
Dairy	4,829	4,033	795
Unknown/Other	5,937	4,854	1,083

Eff_{motor} = 82.5%[36], motor efficiency

For example, using the default assumptions on a 1 horsepower fan thermostat controller for a single fan on a poultry farm:

$$\Delta\text{kWh} = 1\text{ HP} \times 0.75 \times 0.746 \times 372\text{ hours} / 82.5\%\text{ efficency}$$

= 252.3 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A – Assume fans will be in operation at maximum capacity during the coincident peak demand periods, resulting in zero potential demand savings during the hottest periods of the summer.

4.1.6 Low Pressure Sprinkler Nozzles

DESCRIPTION

Incorporating low pressure sprinkler nozzles can decrease the energy and water consumed by reducing required water supply pressure to irrigate crop fields. Low pressure sprinkler nozzles can provide uniform water application by using various orifice applications and configurations while operating at a lower pressure compared to standard, impact driven sprinkler heads. Energy savings are achieved by the irrigation system operating at a lower water pressure while maintaining the same water distribution.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Low Pressure Irrigation Nozzles operate at 35 psi or lower at rated/required flow. Annual Electric Savings obtained will be based on the number of nozzles replaced. To qualify the nozzles must operate for more than 500 hours per year and provide the equivalent flow at the reduced pressure. The maximum pump pressure must also be reduced accordingly.

DEFINITION OF BASELINE EQUIPMENT

This measure applies to the replacement of high pressure irrigation nozzles that operate at 50 psi or greater at rated/required flow.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life expectancy of this measure is 5 years.[37]

DEEMED MEASURE COST

The incremental cost, including labor, is $1.74 per nozzle.[38]

LOADSHAPE

Loadshape C59 – Agriculture and Well Pumping

COINCIDENCE FACTOR

Coincidence Factor = 0.793[39]

4.1.7 Milk Pre-Cooler

DESCRIPTION

There is energy savings for adding a plate heat exchanger (pre-cooler) ahead of the milk storage tank. This addresses the electrical energy savings associated with the decreased milk cooling load. Installing a pre-cooler reduces milk temperature from 100°F to 55-70°F before it enters the bulk tank.

It is important to determine if the site has an adequate supply of water, as milk plate coolers require 1 to 2 times the amount of water as compared to processed milk, to be effective. However, sites leveraging plate coolers will repurpose the warm, discharged water, either for watering cows, wash-down, or other purposes on the farm. As there are indirect benefits associated with the warmer water,[41] and because it is typically repurposed, it is assumed that there are no negative water impacts for this measure. There are also no interactive domestic hot water savings attributable to the installation of a pre-cooler as the discharged water is typically not re-directed to the existing hot water heater.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The installation of the heat exchanger to decrease the cooling requirement of the primary milk bulk tank refrigeration system. The heat exchanger fluid medium used for heat rejection is well or ground water as this produces the largest temperature differential for energy savings. For water requirements, the water supply system must have capacity to keep up with the existing farm water demands and additional demands of the pre-cooler. To minimize the volume of water used for pre-cooling, a solenoid valve should be installed on the water supply line to the pre-cooler and be actuated only when the milk pump is in operation. A bypass line around the solenoid valve or a time delay relay can also be used to provide additional cooling of the residual milk in the pre-cooler between pumping cycles. A storage tank will be necessary for used cooling water storage until it is re-used for watering cows, cleanup or another purpose on the farm.

DEFINITION OF BASELINE EQUIPMENT

The baseline conditions assume that no previous pre-cooler heat exchanger was installed and the entire milk cooling load is on the milk bulk tank.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life expectancy of this measure is 15 years.[42]

DEEMED MEASURE COST

The average equipment cost of a plate cooler is $2,950 with an installation cost of $494, for a total incremental measure of $3,444.[43]

LOADSHAPE

Loadshape C58 – Farm Plate Cooler / Heat Recovery Unit

[41] It is less stressful (metabolically) for cows to drink warmed water, and research has shown that cows will drink more water if it is warmer, leading to increased milk production. 4.1.8 VSD Milk Pump with Plate Cooler Heat Exchanger

DESCRIPTION

This technology incorporates adding a variable speed drive to a milk transfer pump. The VSD drive reduces the heat transferred to milk during pumping operation as well increases the amount of time the milk is in the free cooling heat exchanger. The VFD regulates the milk pump in order to increase the efficacy of the plate cooler heat exchanger by slowing the flow of milk. This results in a maximum heat transfer between the warm milk and the cold water used in the plate cooler.

Energy savings are realized by the reduced load on the primary milk cooling system. A milk transfer pump VSD is only effective if paired with a plate cooler.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Installation of a new variable speed drive (VSD) on a new or existing milk transfer process pump.

DEFINITION OF BASELINE EQUIPMENT

Must have a constant speed milk transfer process pump with no existing VSD controls. A plate cooling heat exchanger can already be a part of the system, or one installed in concert with the VSD.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life expectancy of this measure is 15 years.[51]

DEEMED MEASURE COST

The average equipment cost of a milk vacuum pump variable speed drive is $3,871 with an installation cost of $1,177, for a total incremental measure of $5,048.[52]

LOADSHAPE

Loadshape C57 – Milk Pump

COINCIDENCE FACTOR

There are no summer coincident peak savings for VFD dairy milk pumps. Through research of refrigeration compressor power demands, no substantial evidence has arisen that any notable kW demand reduction is possible in relation to using a VFD with a milk pre-cooler to pre-cool milk that would otherwise need to be chilled through mechanical refrigeration means.

Algorithm

[51] Focus on Energy Evaluation Business Programs Measure Life Study: Final Report August 25, 2009, Public Service Commission of Wisconsin.

[52] The equipment and labor costs are sourced from the PG&E Workpaper – Milk Vacuum Pump VSD, Dairy Farm Equipment (PGE3PAGR116), February 2013.

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{1}{EER} \times C_{p,m} \times \Delta T \times Lbs\ of\ Milk \times Cows \times Days\ /\ 1{,}000$$

Where:

EER	= Efficiency of the existing compressor
	= 8.0 Btu/watt[53]
$C_{p,m}$	= Specific heat of milk
	= 0.93 Btu/lb ˚F[54]
ΔT	= Change in milk temperature as a result of the milk transfer pump VSD. This value is the additional benefits of a VSD on the milk pump over a standard plate cooler
	= 11.7 ˚F[55]
Lbs of Milk	= The pounds of milk produced per day that needs to be cooled
	= 68 lbs of milk per cow[56]
Cows	= Number of milking cows per farm
	= Actual, if unknown use 101[57]
Days	= 365.25 days of milking per year
1,000	= Watts to kW conversion factor

For example, using the default assumptions, the average kWh savings resulting from the installation of a milk transfer pump VSD is:

$$\Delta kWh = \frac{1}{8.0\ Btu/Watt} \times 0.93 \times 11.7°F \times 68\frac{lbs}{milk/cow} \times 101\ cows \times 365\frac{days}{yr} / 1{,}000$$
$$= 3{,}410\ kWh$$

4.1.9 Scroll Compressor for Dairy Refrigeration

DESCRIPTION

Incorporating a more efficient compressor for process milk refrigeration can decrease the energy consumed at dairy farms. This measure is for the installation of a scroll compressor to replace an existing reciprocating compressor on a milk refrigeration bulk tank. The milk refrigeration system is used to cool milk for preservation and packaging. Milk is extracted from the cow at 98°F and cooled to 38°F, resulting in a substantial load on the milk cooling equipment, which is typically the largest energy use on a dairy farm. Scroll compressors can provide increased refrigeration efficiencies with improved EERs over baseline reciprocating compressors.

The energy savings for this measure is dependent on if the site is utilizing pre-cooling equipment such as a milk plate cooler. Plate coolers can reduce the incoming temperature of the milk into the refrigeration bulk tank, reducing the overall load on the compressor and the potential savings benefits.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

For an efficient scroll compressor with or without a plate cooler heat exchanger, the proposed compressor must be rated at 10.6 EER or greater on a process milk refrigeration system. The calculation assumes the cooling capacity of the compressor remains the same.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is assumed to be a reciprocating compressor.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected life of this measure is 15 years.[58]

DEEMED MEASURE COST

The incremental cost is $400 per compressor.[59]

LOADSHAPE

Loadshape C56 – Dairy Farm Combined End Use

COINCIDENCE FACTOR

Coincidence factor of 0.34[60]

Algorithm

[58] Focus on Energy Evaluation Business Programs Measure Life Study: Final Report August 25, 2009, Public Service Comission of Wisconsin.

[59] The incremental cost is sourced from Sanford, Scott (University of Wisconsin-Madison). "Energy Efficiency for Dairy Enterprises." Presentation to Agricultural and Life Sciences Program Staff. December 2014.

[60] Efficiency Vermont (EVT) Technical Reference Manual (TRM), Measure Savings Algorithms and Cost Assumptions, March 16, 2015

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{\left(\frac{1}{EER_{base}} - \frac{1}{EER_{eff}}\right) \times Process\ Load}{1{,}000}$$

Where:

EER_{base} = Efficiency of the existing compressor

= 8.4 Btu/watt[61]

EER_{eff} = Efficiency of the installed, scroll compressor

= 10.6 Btu/watt[62]

Process Load = $C_{P,Milk} \times \Delta T \times Lbs\ of\ Milk \times Cows \times Days$

Where:

$C_{P,Milk}$ = Specific heat of milk

= 0.93 Btu/lb ˚F[63]

ΔT = Change in milk temperature as result of the primary cooling system

= 60˚F without a milk plate cooler[64]

= 30˚F with a milk plate cooler[65]

Lbs of Milk = The pounds of milk produced per day that needs to be cooled

= 68 lbs of milk per cow[66]

Cows = Number of milking cows per farm

= Actual; if unknown use 101[67]

Days = 365 days per year

[61] Average efficiency of a reciprocating compressor, as sourced from Wisconsin Focus on Energy TRM – Plate Heat Exchanger and Well Water Pre-Cooler, 2017

[62] Average efficiency of a scroll compressor, as sourced from Massachusetts Farm Energy: Best Management Practices for Dairy Farms, USDA NRCS, 2012 (page 33)

[63] Specific heat of whole milk, Table 3: Unfrozen Composition Data, Initial Freezing Point, and Specific Heat of Foods, 2014 ASHRAE Handbook - Refrigeration. Page 19.5.

[64] Safe Handling of Milk & Dairy Products. March 8th, 2017 and Sanford, Scott (University of Wisconsin–Madison). "Well Water Precoolers." Publication A37843. October 2003. The temperature of the milk exiting the cow is considered to be 98°F and the final, cooled temperature of the milk is assumed to be 38°F.

[65] The efficacy of a milk plate cooler is sourced from Sanford, Scott (University of Wisconsin–Madison). "Energy Efficiency for Dairy Enterprises." Presentation to Agricultural and Life Sciences Program staff. December 2014. It was assumed that there is a 25°F of milk temperature difference for a single pass plate cooler and a 35°F of temperature difference for a double/multi-pass plate cooler. For the purposes of this measure, a straight average of 30°F between the two types was used. A plate cooler reduces the overall load on the refrigeration compressors and the revised ΔT when accounting for a milk pre-cooler is 30°F less.

[66] "Ag Heat Recovery Tank Supplemental Data." WI Dairy Statistics tab shows USDA reported annual data from: U.S. Department of Agriculture. "Milk Production per Cow, Wisconsin."

[67] The default value for the average number of milking cows per farm is sourced from the 2017 U.S. Census of Agriculture, Illinois State Summary Highlights, Full Report, Volume 1, Chapter 2, U.S. State Level. Average number of cows per farm = 93,341 cows / 924 farms.

1,000 = 1,000 watts to kW conversion factor

For example, using the default assumptions, average kWh savings of an installed scroll compressor on the milk refrigeration bulk tank with a dairy using an existing plate cooler is:

$$\Delta kWh = \frac{\left(\frac{1}{8.4\ EER} - \frac{1}{10.6\ EER}\right) \times \frac{0.93\ Btu}{lb\ of\ Milk} \times (98°\text{F} - 30°\text{F} - 38°\text{F}) \times 68 \frac{lbs\ milk}{cow} \times 101\ cows \times 365\ Days}{1{,}000\ Watts/kW}$$

$$\Delta kWh = 1{,}728\ kWh$$

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh}{Hours} \times CF$$

Where:

Hours = 2,920 hours[68]

CF = 0.34

For example, using the default assumptions, average coincident peak demand savings of an installed scroll compressor on the milk refrigeration bulk tank with a dairy using an existing plate cooler is:

$$\Delta kW = \frac{1{,}728\ kWh}{2{,}920\ Hours} \times 0.34$$

$$\Delta kW = 0.201\ kW$$

MEASURE CODE: CI-AGE-SCRC-V02-240101

REVIEW DEADLINE: 1/1/2029

[68] Raw milk for pasturing must be cooled with 4 hours. Assuming 2 milking per day. Dairy Farm Energy Management Guide: California, Ludington, Johnson, Kowalski, & Mage, Southern California Edison, 2004.

4.1.10 Dairy Refrigeration Heat Recovery

DESCRIPTION

A refrigeration heat recovery (RHR) unit captures waste heat from the refrigeration system and uses a heat exchange to transfer some of that heat into incoming well water. That captured waste heat is used to pre-heat ground water before it enters the primary water heater and brought to the desired final temperature needed for cleaning farm equipment. The hot compressed refrigerant is diverted and flows through the heat exchanger, attached to a secondary water tank, on its way to the condenser unit. The heat from the refrigerant is transferred through the tank into the water. Thermal buoyancy causes the warmest water to rise to the top of the tank. When hot water is used, water flows from the RHR tank into the water heater, and well water flows into the heat recovery tank. These units can assist in reducing water heating energy use by approximately 50%.[69]

It is important to note that if a dairy farm installs an RHR unit and a milk plate cooler, (with or without the use of milk pump VFD control), the plate cooler will impact the savings potential of the RHR unit. The use of a plate cooler will reduce the total milk mechanical refrigeration load. Due to this refrigeration load reduction, the amount of heat rejection possible to the RHR system is diminished.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is farm refrigeration equipment where an RHR tank is installed and captures waste refrigerant heat from the refrigeration system compressor and transfers that waste into an RHR tank, supplied with cool ground water, through a heat exchanger before continuing through the refrigeration system condensing unit. The newly preheated water in the RHR tank is supplied into the farm's main water heater unit, which will have a smaller temperature differential to overcome, compared to a direct ground water heater feed.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is an existing dairy farm with refrigeration equipment and a water heater unit without the use of an RHR unit to feed preheated water to the water heater. Water heater is fed directly with ground water.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected useful life is 15 years.[70]

DEEMED MEASURE COST

The incremental cost is $4,353.[71]

LOADSHAPE

Loadshape C58 – Farm Plate Cooler / Heat Recovery Unit

COINCIDENCE FACTOR

There are no summer coincident peak savings for RHR units. It is assumed that electric water heaters have a single element and will still be used to heat water up to full temperature, and that the kW rating is unchanged when an RHR unit is added in the water heating loop (resulting in no demand reduction).

Algorithm

[71] The incremental cost is sourced from Efficiency Vermont custom project data based on actual equipment installs between 2010 and 2017.

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = Btu_{Recovered} * Days * \left(\frac{1}{EF_{elec}}\right) / 3{,}412$$

Where:

$$Btu_{Recovered} = Btu_{Milk\ Potential}\ or\ Btu_{RHR\ Storage}\ (lesser\ of\ the\ two)$$

Where:

$$Btu_{Milk\ Potential} = Lbs\ of\ Milk * Cows * C_{P,Milk} * \Delta T_{Milk} * SF$$

and

$$Btu_{Storage} = Hot\ Water * C_{P,Water} * P_{Water} * \Delta T_{Water}$$

Days = Number of milking days per year

= 365.25 days[72]

3,412 = Btu to kWh electric conversion factor

EF_{elec} = Energy factor for a standard electric water heater

= 90%[73]

Lbs of Milk = The pounds of milk produced per day per cow that needs to be cooled

=68 lbs of milk per cow[74]

Cows = Number of milking cows per farm

= Actual, if unknown use 101[75]

$C_{P,Milk}$ = Specific heat of milk

= 0.93 Btu/(lb-˚F) [76]

ΔT_{Milk} = Change in milk temperature

= $^{\circ}F_{IN}$ - $^{\circ}F_{FINAL}$

$^{\circ}F_{IN}$ = Temperature of milk being supplied that needs to be cooled

[72] Wisconsin Milk Marketing Board. "Did You Know? Website: Milking Every Day." Accessed December 21, 2015

[73] Talbot, Jacob (American Council for an Energy-Efficient Economy). ACEEE Report A121: Market Transformation Efforts for Water Heating Efficiency. January 2012.

[74] "Ag Heat Recovery Tank Supplemental Data." WI Dairy Statistics tab shows USDA reported annual data from: U.S. Department of Agriculture. "Milk Production per Cow, Wisconsin."

[75] The default value for the average number of milking cows per farm is sourced from the 2017 U.S. Census of Agriculture, Illinois State Summary Highlights, Full Report, Volume 1, Chapter 2, U.S. State Level. Average number of cows per farm = 93,341 cows / 924 farms.

[76] Specific heat of whole milk, Table 3: Unfrozen Composition Data, Initial Freezing Point, and Specific Heat of Foods, 2014 ASHRAE Handbook - Refrigeration. Page 19.5.

= 98˚F if no pre-cooler is used in operation; 68˚F if a milk pre-cooler is used;[77] 56.3˚F if a milk pre-cooler and VFD milk transfer pump are used.[78]

$^{\circ}F_{FINAL}$ = Final stored temperature of cooled milk

= 38˚F

SF = Savings factor for the percentage of energy able to be captured from the milk cooling process

= 55%[79]

Hot Water = Amount of hot water per day in gallons that the site uses for washing and cleaning purposes

= 131.7 gallons[80]

$C_{P,Water}$ = Specific heat of water

= 1 Btu/lb-˚F

P_{Water} = Density of water

= 8.34 lbs/gallon

ΔT_{Water} = Temperature difference = $Temp_{warm\ water} - Temp_{cold\ water}$

$Temp_{warm\ water}$ = 120˚F, expected temperature a refrigeration heat recovery unit can pre-heat well water up to.

$Temp_{cold\ water}$ = 52.3˚F, average well water temperature

SUMMER COINCIDENT PEAK DEMAND SAVINGS

None

FOSSIL FUEL SAVINGS

$$\Delta Therms = Btu_{Recovered} * Days * \left(\frac{1}{EF_{gas}}\right) / 100{,}000$$

Where:

100,000 =Btu to therms natural gas conversion factor

[77] The efficacy of a milk plate cooler is sourced from Sanford, Scott (University of Wisconsin–Madison). “Energy Efficiency for Dairy Enterprises.” Presentation to Agricultural and Life Sciences Program staff. December 2014. It was assumed that there is a 25°F of milk temperature difference for a single pass plate cooler and a 35°F of temperature difference for a double/multi-pass plate cooler. For the purposes of this measure, a straight average of 30°F between the two types was used. A plate cooler reduces the overall load on the refrigeration compressors and the revised ΔT when accounting for a milk pre-cooler is 30°F less.

[78] Sanford, Scott (University of Wisconsin–Madison). “Well Water Precoolers.” Publication A37843. October 2003

[79] DeLaval. “Dairy Farm Energy Efficiency.” April 20, 2011. DeLaval estimates the heat recovery potential to be between 20 and 60%. Based on engineering judgement and further corroboration from the Wisconsin Focus on Energy TRM, opted to default to a 55% savings factor.

[80] The hot water use per day is based on the average hot water requirements per wash cycle multiplied by the number of wash cycles per day. The average amount of hot water used per wash cycle, 47.9 gallons, is sourced from the National Resource Conservation Service for Wash Water Requirements for Milking Systems, a calculator developed by University of Wisconsin, August 2005, Milking Center Waste Volume, v12,05, The number of wash cycles per day account for the hot water rinse cycles that are used to flush and clean the milk lines before and after milking. As sourced from the Regional Technical Forum (RTF) as part of the Northwest Power & Conservation Council, Deemed Measures List; Agricultural: Variable Frequency Drives-Dairy, FY2012, v1.2. Pre- and post-power meter data for five sites were used to establish RTF energy savings and the raw data used to generate load profiles showed, on average, two milkings per day. As there will be one more wash cycle than milking, the default average wash cycles per day is three.

EF_{gas} = Energy factor for a standard natural gas water heater

= 59%

Other variables remain consistent with 'Electric Energy Savings' calculation method.

REVIEW DEADLINE: 1/1/2029

4.1.11 Commercial LED Grow Lights

DESCRIPTION

LED lamp technology offers reduced energy and maintenance costs when compared with conventional light sources. LED technology has a significantly longer useful life lasting 50,000 hours or more and significantly reduces maintenance costs. The savings and costs for this measure are evaluated with the replacement of HID and/or linear fluorescent grow lights with LED fixtures. LED lamps offer a more robust lighting source, longer lifetime, and greater electrical efficiency than conventional supplemental grow lights.

This measure is designed for other interior horticultural applications that use artificial light stimulation in an indoor conditioned space.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

LED fixtures must have a reduced wattage, be listed on the Design Lights Consortium (DLC) qualified products list,[81] be UL Listed, have a power factor (PF) ≥0.90, a photosynthetic photon efficacy (PPE) of no less than 2.5 micromoles per joule, a minimum rated lifetime of 50,000 hours, and a minimum warranty of 5 years for the fixture. If DLC PPE requirements for LED grow lighting exceeds the current requirements, the new PPE will become the efficient equipment standard.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is the industry established grow light based on the horticultural application, as detailed in the table below. HID fixtures are assumed for flowering and vegetative crops. T5 high-output fixtures are assumed for seedling and leafy greens crops.

[81] Design Light Consortium – Horticultural Lighting, Testing and Reporting Requirements for LED-Based Horticultural Lighting, version 4.0, effective April 18, 2025. To date, all horticultural lamps certified by the DLC specification are LEDs.

Crop Type/Growth Stage	Baseline Technology Type	Baseline PPE (µmol/J)[82]	Baseline Fixture Wattage[83]
Flowering and Vine Crops (e.g. Tomatoes, Cucumbers, and Peppers and excludes floriculture applications)	High Pressure Sodium	1.7	1,100 W
Vegetative Growth	Metal Halide	1.25[84]	640 W
Leafy Greens (e.g. Microgreens, Lettuce, and Spinach)[85]	T5 HO Fixture	1.0[86]	358 W
Propagation[87]	T5 HO Fixture	1.0[88]	234 W
Medical Cannabis – Flowering Stage	High Pressure Sodium	1.7	1,100 W
Medical Cannabis – Vegetative Stage	Metal Halide	1.25[89]	640 W
Medical Cannabis – Cloning, Seedling, and Propagation	T5 HO Fixture	1.0[90]	234W
Recreational Cannabis – Flowering Stage	LED	2.2[91]	850 W[92]
Recreational Cannabis – Vegetative Stage	LED	2.2	640 W
Recreational Cannabis – Cloning, Seedling, and Propagation	LED	2.2	234 W

Recreational cannabis cultivation facilities have a separate equipment definition due to Illinois legislation.[93] See cannabis cultivation code from "Cannabis Regulation and Tax Act," Illinois HB 1438:

"The Lighting Power Densities (LPD) for cultivation space commits to not exceed an average of 36 watts per gross square foot of active and growing space canopy, or all installed lighting technology shall meet a photosynthetic photon efficacy (PPE) of no less than 2.2 micromoles per joule fixture and shall be featured on the Design Lights Consortium (DLC) Horticultural Specification Qualified Products List (QPL)."

For new construction applications, for non-recreational cannabis facilities, baseline reverts to IECC 2021 which stipulates the following for lighting for plant growth and maintenance:

[82] Jacob A. Nelson, Bruce Bugbee, "Economic Analysis of Greenhouse Lighting: Light Emitting Diodes vs. High Intensity Discharge Fixtures." Utah State University. Accessed 5/6/2020.
[83] Jacob A. Nelson, Bruce Bugbee, "Economic Analysis of Greenhouse Lighting: Light Emitting Diodes vs. High Intensity Discharge Fixtures." Utah State University. Accessed 5/6/2020.
[84] Jacob A. Nelson, Bruce Bugbee, "Economic Analysis of Greenhouse Lighting: Light Emitting Diodes vs. High Intensity Discharge Fixtures." Utah State University. Accessed 5/6/2020.
[85] Microgreens T5 fixture is based on a 6-lamp high output fixture, based on program experience.
[86] D.S. de Villiers, L.D. Albright, and R. Tuck, "Next Generation, Energy Efficient, Uniform Supplemental Lighting for Closed-System Plant Production." International Society for Horticultural Science. Accessed 4/8/2022.
[87] Propagation T5 fixture is based on a 4-lamp high output fixture, based on program experience.
[88] D.S. de Villiers, L.D. Albright, and R. Tuck, "Next Generation, Energy Efficient, Uniform Supplemental Lighting for Closed-System Plant Production." International Society for Horticultural Science. Accessed 4/8/2022.
[89] Jacob A. Nelson, Bruce Bugbee, "Economic Analysis of Greenhouse Lighting: Light Emitting Diodes vs. High Intensity Discharge Fixtures." Utah State University. Accessed 5/6/2020.
[90] D.S. de Villiers, L.D. Albright, and R. Tuck, "Next Generation, Energy Efficient, Uniform Supplemental Lighting for Closed-System Plant Production." International Society for Horticultural Science. Accessed 4/8/2022.
[91] Recreational cannabis baseline PPE requirement is either 36 W/sqft or 2.2 µmol/J and DLC listed. Per HB 1438.
[92] Recreational cannabis baseline wattage was back calculated using the medical cannabis – flowering stage wattage of 1,100 W and adjusted by the IL HB 1438 minimum fixture efficiency of 2.2 µm/J compared to the typical baseline of 1.7 µm/J.
[93] Illinois legislation Public Act 101-0027 the Cannabis Regulation and Tax Act, Article 20: Adult Use Cultivation Centers, (Section 20-15 (a) (23) a commitment to a technology standard for resource efficiency of the cultivation center facility (B) Lighting)

"Not less than 95 percent of the permanently installed luminaires used for plant growth and maintenance shall have a photon efficiency of not less than 1.6 µmol/J as defined in accordance with ANSI/ASABE S640."

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 9.5 years (average rated life of 50,000 hours).[94]

DEEMED MEASURE COST

The estimated incremental measure cost, excluding recreational cannabis facilities, is assumed to be $501.[95]

For recreational cannabis facilities, incremental costs are estimated to be $80[96], as the baseline for these facilities is assumed to be LED fixtures given the Illinois PPE legislative requirements.

LOADSHAPE

Loadshape C65 – Non-Residential Indoor Agriculture Vegetative Room

Loadshape C66 – Non-Residential Indoor Agriculture Flowering Room

COINCIDENCE FACTOR

Summer coincidence factor for vegetative and flowering rooms = 0.95

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

PPF Equivalence Method:

$$\Delta kWh = \left[\left(\frac{PPF_{Total,i}}{PPE_{BL,i} \times 1000}\right) - kW_{ee,i}\right] \times Hours \times WHF_e$$

$$PPF_{Total,i} = PPF_{Fixture,i} \times Qty_i$$

Where:

$PPF_{Total,i}$ = Total Photosynthetically-active Photon Flux output of the installed efficient fixtures for a specific growth phase, i in units of µmol/s. Equal to the number of fixtures installed multiplied by the PPF output per fixture.

$PPE_{BL,i}$ = Photosynthetically-active Photon Flux Efficiency of the assumed baseline fixture for a specific growth phase, i in units of µmol/J. Can be found in the table above.

[94] Based on 50,000 hours lifetime and 5,250 hours per year of use (average hours of use per year using flowering and vegetative rooms).

[95] Incremental costs are sourced from the Wisconsin Focus on Energy 2025 Technical Reference Manual, January 29, 2025 – Grow Light System, Agriculture, and include an estimated blend of baseline HID fixtures that fit the measure replacement scenario.

[96] LED fixture costs are based on a 2023 review of online retailers, conducted for the California eTRM, LED Indoor Horticulture, published April 18, 2025.

$PPF_{Fixture,i}$ = The Photosynthetically-active Photon Flux output of an individual fixture installed for a specific growth phase, i in units of µmol/s.[97]

Qty_i = The installed quantity of efficient fixtures.

i = An indicator used to separate growth phases of products or different plants. "i" can be used to separate "Flowering" and "Vegetative", or different crop types, such as "Flowering Crops (tomatoes and peppers)" and "Microgreens".

1000 = Watts to kilowatts conversion factor

$kW_{ee,i}$ = Total power of the installed fixtures for a specific growth phase, i.

Hours = Annual operating hours. See table below for typical hours of operation breakdown by crop type.

Crop Type/Growth Stage	Hours of Operation per Day[98]	Annual Hours of Operation[99]
Flowering and Vine Crops (e.g. Tomatoes, Cucumbers, and Peppers and excludes floriculture applications)	12	4,200
Vegetative/Propagation Growth Stage	18	6,300
Leafy Greens (e.g. Microgreens, Lettuce, and Spinach)	18	6,300
Medical Cannabis – Flowering Stage	12	4,200
Recreational Cannabis – Flowering Stage	12	4,200
Greenhouse[100]	N/A	2,120

WHFe = 1.21[101] if cooling or unknown or 1.00 if none; waste heat factor for energy to account for cooling savings from efficient lighting in cooled buildings.

For example, a recreational cannabis growth facility is installing 100 efficient LED fixtures in their flowering spaces. Using the manufacturer and model number, the DLC Qualified Products List for horticulture lighting lists these fixtures as consuming 529W and having a Photosynthetic Photon Efficiency (PPE) of 3.3 µmol/J and producing 1,722 µmol/s. One hundred (100) fixtures at 529W each is a total lighting power of 52.9 kW. The baseline PPE is 2.2 µmol/J, as dictated by IL HB 1438. The total flux output and annual energy savings calculations are shown below.

$$PPF_{Total,i} = (1{,}722\ \mu mol/s) \times 100\ fixtures = 172{,}200\ \mu mol/s$$

[97] Individual fixture PPF can be sourced directly from the DLC horticulture qualified products list, Design Light Consortium – Horticultural Lighting, Testing and Reporting Requirements for LED-Based Horticultural Lighting, version 4.0, effective April 18, 2025.

[98] Sole-Source Lighting of Plants. Technically Speaking by Erik Runkle. Michigan State University Extension. September 2017. Accessed: 7/29/2019.

[99] Annual hours of operation were found by multiplying hours per day by 350 operating days per year. Assuming 5 crop cycles with 3 days of downtime between each cycle

[100] Supplemental lighting for greenhouses varies monthly and fluctuates depending on the available daylight hours. As a result, only annual hours of operation for greenhouses is available and sourced from, Energy Savings Potential of SSL in Horticultural Applications, U.S. DOE, December 2017

[101] Waste heat factor for cooling savings calculation can be found in the Indoor Agriculture Loadshapes excel file.

$$\Delta kWh = \left[\left(\frac{172{,}200\ \frac{\mu mol}{s}}{2.2\ \frac{\mu mol}{J} \times 1000}\right) - (52.9\ kW)\right] \times 4{,}200\ hours \times 1.21$$

= 128,944 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \left[\left(\frac{PPF_{Total,i}}{PPE_{BL,i} \times 1000}\right) - kW_{ee,i}\right] \times CF \times WHF_d$$

Where:

WHF_d = 1.22 if cooling or 1.00 if none; waste heat factor for demand to account for cooling savings from efficient lighting in cooled buildings.

CF = 0.95 for vegetative crops and flowering crops

For example, a recreational cannabis growth facility is installing 100 efficient LED fixtures in their flowering spaces. Using the manufacturer and model number, the DLC Qualified Products List for horticulture lighting lists these fixtures as consuming 529W and having a Photosynthetic Photon Efficiency (PPE) of 3.3 µmol/J and producing 1,722 µmol/s. One hundred (100) fixtures at 529W each is a total lighting power of 52.9 kW. The baseline PPE is 2.2 µmol/J, as dictated by IL HB 1438. The total flux output and peak demand savings calculations are shown below.

$$PPF_{Total,i} = (1{,}722\ \mu mol/s) \times 100\ fixtures$$ = 172,200 µmol/s

$$\Delta kWh = \left[\left(\frac{172{,}200\ \frac{\mu mol}{s}}{2.2\ \frac{\mu mol}{J} \times 1000}\right) - (52.9\ kW)\right] \times 0.95 \times 1.22$$

= 29.41 kW

MEASURE CODE: CI-AGE-GROW-V08-260101

REVIEW DEADLINE: 1/1/2028

4.1.12 Swine Heat Pads

DESCRIPTION

This measure applies to the large Commercial and Industrial sector, specifically for the agriculture industry. Swine farmers will typically keep their newborn piglets alongside their mothers (sows) for up to three to four weeks until they gain sufficient weight and can be moved to a nursery barn. During this farrowing stage, the piglets must be kept at temperatures ranging from 32 to 35°C (90 to 95°F). A sow and her piglets are kept in private farrowing crates, where the sow is kept in a separate and railed cage. This allows the piglets to still suckle from their mother and keeps the sow from crushing her piglets. These farrowing crates can be arranged in single or double systems. Typically, farmers will utilize a heat lamp as the primary heating source for these piglets, which can range from 125 W to 250 W and have an average measure life of 5,000 hours. More energy efficient technology has emerged in the form of heated mats. These mats require significantly less energy than a traditional heat lamp and have no known negative impacts on piglet health. Heating mats come in two options, single (typically rated at ≤100W) or double (typically rated at ≤200W) mats. Single mats serve one litter, and double mats serve two litters.

DEFINITION OF EFFICIENT EQUIPMENT

The use of heat mats in swine farrowing will result in electrical savings for the customer. Research has also shown that newborn piglets do not prefer mat heating over lamp heating, but as they grow, they tend to prefer mat heating. Applied research in large industrial settings found no significant differences between lamp and mat heating on the behavior and well-being of piglets. Therefore, the only difference to note between the two methods is the energy saved in using heating mats.

DEFINITION OF BASELINE EQUIPMENT

The baseline measure for swine farrowing heating is heat lamps, typically ranging from 125 to 250 Watts. Most studies conducted on swine farrowing heat lamps have used 125 watt or 175 watt lamps per litter.[102,103]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life of a farrowing heat mat is 5 years.[104]

DEEMED MEASURE COST

Heat mat prices will vary somewhat with size but a typical single mat costs $155 and double mat costs $280.[105] Additional costs can be incurred if a thermostat controller is included, these start at $240 but vary widely depending on controller complexity.

LOADSHAPE

[105] Hog Slat. (2023). Heat Pad. Online pricing catalogue for agriculture and livestock equipment.

[106] Coincidence factor is taken from the IL TRM loadshape C04 – Non-residential Electric Loadshape.

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$kWh_{saved} = kWh_{base} - kWh_{EE} - kWh_{controller}$$

$$kWh_{base} = \frac{Crates_{total} \times Hours \times Fixture_{crate} \times Lamp_{fixture} \times Wattage_{lamp}}{1000 \frac{Watts}{kW}}$$

$$kWh_{EE} = \frac{Hours \times \left(Mats_{single} \times Wattage_{single} + Mats_{double} \times Wattage_{double}\right)}{1000 \frac{Watts}{kW}}$$

$$kWh_{controller} = \frac{Hours \times Rooms \times \left(MSU_{room} \times MSU_{wattage}\right)}{1000 \frac{Watts}{kW}}$$

Where:

$$Crates_{total} = \left(Crates_{single-row} + Crates_{double-row}\right) \times Rows \times Rooms$$

$$Mats_{Single} = Crates_{single-row} \times Rows \times Rooms$$

$$Mats_{Double} = Crates_{double-row} \times Rows \times Rooms$$

$Crates_{total}$ = Number of Farrowing Crates

$Crates_{single\text{-}row}$ = Number of single crates in a row

$Crates_{double\text{-}row}$ = Number of double crates in a row

Rows = Number of rows in a room

Rooms = Number of rooms in a farrowing barn

$Mats_{single}$ = Number of single mats

$Mats_{double}$ = Number of double mats

$Wattage_{single}$ = Default 90W with no MSU, 61W with MSU*; Wattage of a single heat mat

$Wattage_{double}$ = Default 180Wwith no MSU, 122W with MSU*; Wattage of a double heat mat

Hours = Default 5,105 hours;[107] Annual hours of operation

$Fixture_{crate}$ = Number of heat lamp fixtures per farrowing crate

$Lamp_{fixture}$ = Number of heat lamps per fixture

$Wattage_{lamp}$ = Default 125W or 175W; Heat lamp wattage

MSU_{room} = Default 1; Number of master sensor units (MSU) per room

$MSU_{wattage}$ = Default 75W; Wattage of master sensor unit

[107] While heat mat hours do vary from heat lamps slightly, the savings assumptions match heat lamp hours for consistency. Calculation method from Iowa State University farm manager (Ben Drescher): "At minimum I'd say they are on 24-7 from Oct-March and March-May, and 12 hours a day June-September 8 hours a day. You'd also take off for power washing etc. so if you had a 24 day turn in a farrowing room you'd run them for 21 days and turn the room subtract 3 days from x 15 turns a year - resulting in 5120 hours." Cadmus did not round data and estimated 5,105 hours. Email sent 10/23/15. "FW: Heat lamp bulbs". Itron benchmarked the HOU with their own analysis which resulted in 5,109 hours: 30.42 days/month; 3 months (summer) run 33% of time; 6 months run 50% of time; 3 months (winter) run full time.

DEFAULT SAVINGS FOR SINGLE UNIT REPLACEMENT

Replacement Type	Baseline Heat Lamp	Annual kWh Savings
Single Mat replacing one Heat Lamp w/o MSU	125W	178.7
Single Mat replacing one Heat Lamp w/ MSU		326.7
Double Mat replacing two Heat Lamps w/o MSU		357.4
Double Mat replacing two Heat Lamps w/ MSU		653.4
Single Mat replacing one Heat Lamp w/o MSU	175W	433.9
Single Mat replacing one Heat Lamp w/ MSU		582.0
Double Mat replacing two Heat Lamps w/o MSU		867.9
Double Mat replacing two Heat Lamps w/ MSU		1163.9

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$kW_{Saved} = (kWh_{Saved}/Hours) \times CF$$

Where:

kWh_{Saved} = kWh savings, see above equation and table.

Hours = Operating hours, 5,105.

CF = Coincidence Factor, 0.018.[108]

DEFAULT SAVINGS FOR SINGLE UNIT REPLACEMENT

Replacement Type	Baseline Heat Lamp	Peak kW Savings
Single Mat replacing one Heat Lamp w/o MSU	125W	0.0006
Single Mat replacing one Heat Lamp w/ MSU		0.0012
Double Mat replacing two Heat Lamps w/o MSU		0.0013
Double Mat replacing two Heat Lamps w/ MSU		0.0023
Single Mat replacing one Heat Lamp w/o MSU	175W	0.0015
Single Mat replacing one Heat Lamp w/ MSU		0.0021
Double Mat replacing two Heat Lamps w/o MSU		0.0027

[108] Coincidence factor is taken from the IL TRM loadshape C04 – Non-residential Electric Loadshape.

Replacement Type	Baseline Heat Lamp	Peak kW Savings
Double Mat replacing two Heat Lamps w/ MSU		0.0041

DEEMED O&M COST ADJUSTMENT CALCULATION

Approximately 1% of mats are likely to be damaged by swine each year and require full replacement.

Additionally, depending on the flooring, some mats may become loose on steel slated floors. This can be prevented by buying mats that have a channel or groove where it sits in the partition. Another option is to buy tie down clips that cost approximately $24 per double mat.[109]

The NPV for replacement heat lamps and annual levelized replacement costs using the societal real discount rate of 0.42% are presented below. The O&M cost adjustments are based on a 1-year measure life for heat lamps and a 5-year analysis period for heat pads. The measure life assumptions indicate an annual lamp replacement cost for the baseline equipment. The heat lamp replacement cost is assumed to be $5.50.[110]

Replacement Type	NPV of Replacement Costs for Period	Levelized Annual Replacement Cost Savings
Single Mat replacing one Heat Lamp	$20.58	$4.94
Double Mat replacing two Heat Lamps	$41.16	$8.98

MEASURE CODE: CI-AGE-HPAD-V02-240101

REVIEW DEADLINE: 1/1/2029

[109] Franklin Energy field experience

[110] The cost of a replacement heat lamp bulb is sourced from an average of available products via online pricing for agriculture equipment and heat lamps. For more information on the cost of a heat lamp and the derivation of O&M cost savings, please see: "Swine Heat Pads_OM.xlsx".

4.1.13 Irrigation Pump VFD

DESCRIPTION

This measure applies to variable speed drives (VSD) installed on irrigation pump motors for the agriculture industry. This characterization does not apply to positive displacement pumps. The VFD will modulate the speed of the motor when it does not need to run at full load. Since the power of the motor is proportional to the cube of the speed for these types of applications, significant energy savings will result.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The VFD is applied to a motor that does not yet have one. The irrigation system must have a variable load, and installation is to include the necessary controls as determined by a qualified engineer. Savings are based on application of VFDs to a range of baseline load conditions.

DEFINITION OF BASELINE EQUIPMENT

The time of sale baseline is a new motor installed without a VFD or other methods of control. The retrofit baseline is an existing motor operating as is. Retrofit baselines may or may not include guide vanes, throttling valves, or other methods of control. This information shall be collected from the customer.

Installations of new equipment with VFDs that are required by IECC 2018 as adopted by the State of Illinois are not eligible to claim savings[111].

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 15 years.[112]

DEEMED MEASURE COST

Customer provided costs will be used when available. Default measure costs[113] are noted below for up to 75 hp motors. Custom costs must be gathered from the customer for motor sizes not listed below.

HP	Cost
1-9 HP	$1,874
10-19 HP	$2,967
20-29 HP	$4,060
30-39 HP	$5,154
40-49 HP	$6,247
50-59 HP	$7,340
60-69 HP	$8,433
70-75 HP	$9,526

LOADSHAPE

Loadshape C59 – Agriculture and Water Pumping

COINCIDENCE FACTOR

The installation of a VFD on an irrigation pump should not cause any energy reduction during peak runtimes.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = \text{kWh}_{\text{Base}} - \text{kWh}_{\text{VFD}}$$

$$kWh_{Base} = \sum_{1}^{\eta} HP_{\eta} * 0.746 \frac{kW}{HP} * Hours_{year} * \%Hours_{\eta}$$

$$kWh_{VFD} = \sum_{1}^{\eta} HP_{VFD,\eta} * 0.746 \frac{kW}{HP} * Hours_{year} * \%Hours_{\eta}$$

$$HP_{\eta} = \frac{Flow_{\eta} * Head_{\eta}}{3960 \times (Eff_{pump} * Eff_{motor})}$$

$$HP_{VFD,\eta} = \frac{Flow_{\eta} \times Head_{VFD,\eta}}{3960 \times (Eff_{pump} * Eff_{VFD} * Eff_{motor})}$$

$$Hours_{year} = \frac{Acres \times Irrigation}{12 \frac{in}{ft} * 60 \frac{min}{hr} * GPM_{System} \Big/ \left(7.481 \frac{gal}{ft^3} * 43{,}560 \frac{ft^2}{acre}\right)}$$

Where:

kWh_{Base}	= Annual energy required for the baseline pump condition
kWh_{VFD}	= Annual energy required with a VFD pump installed
HP_{η}	= Baseline horsepower required for a given flow rate
$\text{HP}_{\text{VFD},\eta}$	= Horsepower required for a given flow rate with the VFD installed
$\text{Hours}_{\text{year}}$	= Annual Hours of irrigation
$\%\text{Hours}_{\eta}$	= Percent of time irrigation pump will be operating at a given flow rate
η	= Number of data points needed or collected
Flow_{η}	= Flow rate at a given data point in gallons per minute, use actual values
Head_{η}	= Pressure head at a given data point in feet, use actual values
$\text{Head}_{\text{VFD},\eta}$	= Pressure head at a given data point in feet with a VFD
Eff_{pump}	= Percent efficiency of the pump, taken from manufacturers pump curve
$\text{Eff}_{\text{motor}}$	= Percent efficiency of the pump motor

4.1.14 High Efficiency Grain Dryer

DESCRIPTION

This measure characterizes the energy savings from the replacement of an existing inefficient grain dryer with a new efficient grain dryer (Early Replacement incentive program). Alternatively, this measure is for the purchase of a new high efficiency grain dryer instead of a new standard efficiency grain dryer for an existing facility (Time of Sale program) or a new facility (New Construction incentive program). Energy savings are achieved by drying grain more efficiently through: improved dryer air flow design, improved dryer controls, warm air heat recovery, and burner efficiency improvements. Efficient dryers also have the benefits of increased throughput capacity and reduced annual hours of operation.

This measure was developed to be applicable to the following program types: TOS, EREP, and NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is assumed to be a new, high efficiency grain dryer. Bushels per hour must be provided by the manufacturer, as rated at 5% moisture removal rate per bushel processed.

DEFINITION OF BASELINE EQUIPMENT

The baseline for this measure is a standard efficiency grain dryer currently on the market. Bushels per hour must be provided by the manufacturer, as rated at 5% moisture removal rate per bushel processed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for the energy-efficient grain dryer is deemed to be 20 years[116].

DEEMED MEASURE COST

If known, the actual material and labor cost of installation should be used. If unknown, the cost of the measure is assumed to be the values summarized in the table below:

Tier (bushels per hour)	Tier (annual bushels)	High-Efficiency Dryer Total Installation Cost (for Early Replacement only)	Average Incremental Cost of of High-Efficiency Dryer vs Standard Dryer	Average Incremental Cost of Variable Speed Drive added to Cost of High-Efficiency Dryer
<500	< 170,000	$83,000 (Based on baseline price of $50,000 + ($50/Bu/hr * 250 Rated Bu/hr) + Incremental Cost of High Efficiency)	$20,000	$4,000 (Based on baseline price of $2,500 + 0.046kW/Bu/hr * 250 Rated Bu/hr) *$100/kW)
≥ 500 and < 1,000	≥ 170,000 and < 330,000	$118,000 (Based on 750 Rated Bu/hr)	$30,000	$6,000 (Based on 750 Rated Bu/hr)
≥ 1,000 and < 2,000	≥ 330,000 and < 670,000	$165,000 (Based on 1,500 Rated Bu/hr)	$40,000	$9,000 (Based on 1,500 Rated Bu/hr)

[116] Iowa State University Ag Extension, "Computing a Grain Storage Rental Rate", October 2013. The useful life of grain storage bins was estimated to be between 15 and 25 years and the drying equipment useful life was estimated to be between 10 and 12 years. Combined with engineering judgement, the estimated measure life for a high efficiency grain dryer is estimated to be 20 years, which is corroborated by the Wisconsin Focus on Energy 2021 Technical Reference Manual, Cadmus, Publich Service Commission of Wisconsin – Energy Efficient Grain Dryer.

Tier (bushels per hour)	Tier (annual bushels)	High-Efficiency Dryer Total Installation Cost (for Early Replacement only)	Average Incremental Cost of of High-Efficiency Dryer vs Standard Dryer	Average Incremental Cost of Variable Speed Drive added to Cost of High-Efficiency Dryer
≥ 2,000 and < 3,500	≥ 670,000 and < 1,200,000	$258,000 (Based on 2,750 Rated Bu/hr)	$70,000	$15,000 (Based on 2,750 Rated Bu/hr)
≥ 3,500 and ≤ 5,000	≥ 1,200,000 and ≤ 1,700,000	$363,000 (Based on 4,250 Rated Bu/hr)	$100,000	$22,000 (Based on 4,250 Rated Bu/hr)
> 5,000	> 1,700,000	$488,000 (Based on 6,250 Rated Bu/hr)	$125,000	$31,000 (Based on 6,250 Rated Bu/hr)

Early Replacement: The full installation cost is provided in the table above. The assumed deferred cost (after 6.5 years [one third of useful life]) of replacing existing equipment with a new baseline unit is assumed to be the installation cost discounted to present value using the nominal discount rate.

LOADSHAPE

Loadshape NRE11 – Non-Residential Agriculture

COINCIDENCE FACTOR

There are no summer peak savings associated with this measure as it is assumed grain dryers do no operate during peak summer months.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

If grain dryer is heated exclusively with electricity:

$$\Delta kWh = Bushels/Hr_{Capacity} * Annual_Hr_Use_{@Rated_Capacity} * (Moisture_\%_{In} - Moisture_\%_{Out}) * Grain_Lb_Moisture_/_Bushel * Btu/Lb_{Evap} * (1 / Dryer_Effcy_{Std} - 1/ Dryer_Effcy_{Eff}) / 3{,}412 + (Dryer_Fan_Power_{Standard} - Dryer_Fan_Power_{Efficient}) * Bushels/Hr_{Capacity} * Annual_Hr_Use_{@Rated_Capacity}$$

Where:

$Bushels/Hr_{Capacity}$ = Capacity of Grain Dryer in Bushels/Hr when reducing grain moisture content by 5%

$Annual_Hr_Use_{@Rated_Capacity}$ = Average annual hours of use of typical grain dryer

= Deemed value of 336.3 hr/year[117]

[117] Alliant Energy Custom Rebate project data from 2012-2014; original Alliant table was modified, adding a new column of hours per year use and renaming labels. Annual tier production quantities (bushels/yr) were divided by the maximum nominal tier capacities (bushels/hr @ rated capacity) to obtain Hours per Year @ Rated Capacity. Arithmetic average hours of use was 336.3 per year.

Annual hours of use were calculated based on following table. Deemed value is arithmetic average of Average Use per Year

Savings Tier (Bushels/hr) from Manufacturer	Savings Tier (Bushels/yr)	Average Hours/yr @ Rated Capacity
>= 0 Bu/Hr	170,000	340
>= 500 Bu/Hr	330,000	330
>= 1,000 Bu/Hr	670,000	335
>= 2,000 Bu/Hr	1,200,000	343
>= 3,500 Bu/Hr	1,700,000	340
>= 5,000 Bu/Hr	2,475,000	330

Moisture_$\%_{In}$ = 23%[118], a deemed value representing average % moisture in grain arriving at grain dryer facility[119]

Moisture_$\%_{Out}$ = 15%[120], a deemed value representing average % moisture in grain after being dried at grain dryer facility

Grain_Lb_Moisture_/_Bushel = Lookup value from following table, Lb Moisture per Bushel per 1% of moisture content reduction. [121]

[118] Wisconsin Focus on Energy project data; 13 recent grain dryer projects in Wisconsin were used as the source of average pre- and post- moisture content (23% and 15%, respectively) and baseline and proposed dryer efficiency.

[119] The National Corn Handbook. "Energy Conservation and Alternative Sources for Corn Drying." NCH-14, page 3, Table 4. http://corn.agronomy.wisc.edu/Management/NCH.aspx

[120] Wisconsin Focus on Energy project data; 13 recent grain dryer projects in Wisconsin were used as the source of average pre- and post- moisture content (23% and 15%, respectively) and baseline and proposed dryer efficiency.

[121] "Tables for Weights and Measurement: Crops". Murhpy, William J. Table shown was modified from the original by eliminating some redundant rows for similar crops, and by adding a new column that calculates pounds of moisture evaporated per Standard Bushel per 1% moisture reduction by the dryer.

Grain Type	Weight of "Standard Bushel"	Lb Moisture/Bu/1% Evap
Alfalfa	60.0 Lb/Std Bu	0.60 Lb Evap/Std Bu/Delta%
Barley	48.0 Lb/Std Bu	0.48 Lb Evap/Std Bu/Delta%

Efficient Electric Bin Grain Dryer w/ Damper Fan Operation	88%	1,120	0.035
Efficient Electric Bin Grain Dryer w/ Fan VFD	88%	1,120	0.002

$Dryer_Effcy_{Eff}$ = Actual or a deemed value based upon above table. If unknown assume 88%[123]. See prior footnote for derivation of this value.

3,412 = Conversion factor of kWh to Btu; engineering constant.

$Dryer_Fan_Power_{Standard}$ = 0.044 kW/Bu[124], from above table, a deemed value, based on the following average standard bin dryer operational parameters, and the engineering equation:

kW/Bu_{Std} = CFM/Bu_{Std} * $in._wc_{Std}$ / 6,354 / $Fan_Effieciency_{Std}$ * 0.746 / $Motor_Effcy_{Std}$.

In the above equation, the following deemed constants are typical for standard-efficiency Grain Dryers:

Where:

CFM/Bu_{Std} = 61 CFM/Bu

$in._wc_{Std}$ = 3.0" wc

6,354 =Units conversion from cfm * in. wc. / Fan_Efficiency to BHP

$Fan_Effieciency_{Std}$ = 60%

0.746 = Units conversion from BHP to kW

$Motor_Effcy_{Std}$ = 80%.

kW/Bu = 61 * 3.0 / 6,354 / 60% * 0.746 / 80%
= 0.044 kW/Bu

[123] Alliant Energy Custom Rebate project data from 2012-2014; same comments apply as in prior footnote.
[124] The Standard Dryer Fan Power using the fan brakehorsepower equation.

Dryer_Fan_Power$_{Efficient}$ = 0.035 kW/Bu[125], if fan volume is controlled using outlet damper, or

= 0.002 kW/Bu, if fan volume is controlled using VFD.

Above values are deemed constants, based on the following average high-efficiency bin dryer operational parameters, and the engineering equation:

kW/Bu$_{Eff}$ = CFM/Bu$_{Eff}$ * in._wc$_{Eff}$ / 6,354 / Fan_Effieciency$_{Eff}$ * 0.746 / Motor_Effcy$_{Eff}$ / Drive_Effcy$_{Eff}$

In the above equation, the following deemed constants are assumed to apply to high-efficiency Grain Dryers:

Where:

CFM/Bu$_{Eff}$	= 22
in._wc$_{Eff}$	= 4.4” if Outlet Damper control; 0.4” if VFD control
6,354	=Units conversion from cfm * in. wc. / Fan_Efficiency to BHP
Fan_Effieciency$_{Eff}$	= 60%
0.746	= Units conversion from BHP to kW
Motor_Effcy$_{Eff}$	= 80%
Drive_Effcy$_{Eff}$	= 100% if Outlet Damper control; 95% if VFD control.

For high-efficiency dryer with VFD control:

kW/Bu = 22 * 0.4 / 6,354 / 60% * 0.746 / 80% / 95%
= 0.002 kW/Bu

For example, using the default assumptions on the installation of a 3,000 bushels/hr electric grain dryer with Outlet Damper used for Alfalfa:

$$\Delta kWh = (3{,}000 * 336.3 * (0.23 - 0.15) * 0.60 * 990 * (1/0.71 - 1/0.88)/3{,}412) + ((0.044 - 0.035) * 3{,}000 * 336.3)$$

= 12,903 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

If grain dryer is heated exclusively with natural gas:

$$\Delta Therms = Bushels/Hr_{Capacity} * Annual_Hr_Use_{@Rated_Capacity} * (Moisture_\%_{In} - Moisture_\%_{Out}) * Grain_Lb_Moisture_/_Bushel * Btu/Lb_{Evap} * (1 / Dryer_Effcy_{Std} - 1/ Dryer_Effcy_{Eff}) / 100{,}000$$

Where:

100,000	= Conversion factor of Therms to Btu; engineering constant.

[125] The same Dryer Fan Power formula as in the above footnote.

All variables are as defined and derived in the preceding electric savings calculations, but using values in the dryer efficiency table above for Baseline or Efficient "Gas or Propane Grain Dryer".

Note: When a variable frequency drive (VFD) is incorporated on the drying fan, electrical savings may be claimed by the fan power derivation in the electric savings algorithm for additive electrical savings for a gas heated grain dryer.

For example, using the default assumptions on the installation of a 3,000 bushels/hr gas grain dryer with Outlet Damper used for Alfalfa:

ΔTherms = 3,000 * 336.3 * (0.23 - 0.15) * 0.60 * 990 * (1/0.44 - 1/0.61)/100,000

= 303.7 Therms

4.1.15 Grain Dryer Tune-Up

DESCRIPTION

This measure is for commercial grain dryers for agricultural operations. Tune-ups improve grain drying efficiency by maintaining dryer components that have become clogged, dirty, or uncalibrated. This measure involves cleaning and/or inspecting burners, fans, and screens and cleaning and recalibrating all temperature and moisture sensors, if applicable.

Crops such as grain, soybeans, and corn need to be dried after harvest to prevent rot, mold, and animals from destroying the crop. After harvest, these wet crops are loaded into a grain dryer where they are dried. Grain drying processes vary but consist of warm (or high temperature) air forced through the crop. The air may be heated electrically or by fossil fuels. Once the grain is dried, it is stored in grain bins or silos until transport. At the time of harvest, moisture content inside grain varies between 17% and 40%. After drying, moisture levels are kept between 13% and 14% to improve shelf life. Maintaining peak efficiency of grain dryers through tune-ups is important for equipment efficiency and grain drying performance. Tune-ups save energy by removing impediments to airflow and calibrating sensors so that equipment capacity is maximized and drying time is minimized.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the facility must, as applicable, complete the tune-up requirements by an approved technician as specified below:

- Inspect and clean screens
- Inspect and clean fans
- Clean and calibrate all temperature sensors
- Clean and calibrate all moisture sensors*
- Inspect and adjust grain dryer controls including temperature setpoint, as needed
- Lubricate bearings

Task marks with an asterisk (*) are only required if the existing grain dryer contains this equipment.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition of this measure is a commercial-grade grain dryer that has not been tuned-up within the past 12 months.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life of this measure is 1 year.[126]

DEEMED MEASURE COST

The cost of this measure is $500.00, which includes service and labor.[127]

LOADSHAPE

COINCIDENCE FACTOR

N/A

[126] University of Wisconsin-Madison Extension. “Low Cost Energy Conservation: Grain Drying (A3784-10).” Tune-Ups are recommended annually because of the dusty environment components are subject to during the grain drying process. Although farms often defer grain dryer maintenance, the energy savings will not persist over multiple seasons.
[127] From Wisconsin Focus on Energy 2020 Technical Reference Manual, Grain Dryer Tune-Up (pg. 44). Incremental costs are based on trade ally survey.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = Bushels_{ANNUAL} * kWh\ Saved\ per\ Bushel$$

Where:

$Bushels_{ANNUAL}$ = Number of bushels of grain to be dried per year (bushels/yr)

= Custom

Where:

$$kWh\ Saved\ per\ Bushel = \left(GD_{EFF} * Lbs_{H2O\ REMOVED} * \frac{kWh\%}{3{,}412}\right) * SF$$

Where:

$kWh\ Saved\ per\ Bushel$ = Amount of energy saved per bushel of grain dried. Use actual if known. If unknown, default to calculated values in table below based on grain dryer type and efficiency.

GD_{EFF} = Existing grain dryer efficiency (Btu/Lbs_H20)

= Custom, or default value in table below based on type of grain dryer

Grain Dryer Type	GD_EFF (Btu/Lbs_H2O)[128]	kWh%[129]	kWh Saved per Bushel	Therm Saved per Bushel
Low Temperature Bin Dryer	1,600	100%	0.11723	0
Continuous Mixed Flow Bin Dryer	2,000	2%	0.00293	0.00490
Mixed Flow Dryer	2,000	2%	0.00293	0.00490
High Temperature Batch Bin Dryer	2,400	2%	0.00352	0.00588
Continuous Cross-Flow (Tower) Dryer	2,400	2%	0.00352	0.00588
Cross-Flow Batch Dryer	2,500	2%	0.00366	000613

$$Lbs_{H2O\ REMOVED} = Grain_{LBS\ MOISTURE} * (\%\ Moisture_{IN} - \%\ Moisture_{OUT})$$

Where:

$Lbs_{H2O\ REMOVED}$ = Pounds of water removed per bushel

= Default value in table or Custom calculation as detailed below

4.1.16 Greenhouse Boiler Tune-Up

DESCRIPTION

This measure is for a non-residential greenhouse boiler. For space heating other than greenhouses, see measure 4.4.2 Space Heating Boiler Tune-Up. For process heating other than greenhouses, see measure 4.4.3 Process Boiler Tune-Up. The tune-up will improve boiler efficiency by cleaning and/or inspecting burners, combustion chamber, and burner nozzles. Adjust air flow and reduce excessive stack temperatures, adjust burner and gas input. Check venting, safety controls, and adequacy of combustion air intake. Combustion efficiency should be measured before and after tune-up using an electronic flue gas analyzer.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the facility must, as applicable, complete the tune-up requirements by approved technician[135] as specified below:

- Measure combustion efficiency using an electronic flue gas analyzer
- Adjust airflow and reduce excessive stack temperatures
- Adjust burner and gas input, manual or motorized draft control
- Check for proper venting
- Complete visual inspection of system piping and insulation
- Check safety controls
- Check adequacy of combustion air intake
- Clean fireside surfaces
- Inspect all refractory. Patch and wash coat as required.*
- Inspect gaskets on front and rear doors and replace as necessary.*
- Seal and close front and rear doors properly.*
- Clean low and auxiliary low water cut-off controls, then re-install using new gaskets.*
- Clean plugs in control piping.*
- Remove all hand hole and man hole plates. Flush boiler with water to remove loose scale and sediment.*
- Replace all hand hole and man hole plates with new gaskets.*
- Open feedwater tank manway, inspect and clean as required. Replace manway plate with new gasket.*
- Clean burner and burner pilot.
- Check pilot electrode and adjust or replace.
- Clean air damper and blower assembly.
- Clean motor starter contacts and check operation.*
- Make necessary adjustments to burner for proper combustion.
- Perform all flame safeguard and safety trip checks.
- Check all hand hole plates and man hole plates for leaks at normal operating temperatures and pressures.
- Troubleshoot any boiler system problems as requested by on-site personnel

Note: Tune-up activities marked with an asterisk (*) are eligible to be performed by internal maintenance staff at periods of boiler shutdown.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition of this measure is a boiler that has not had a tune-up within the past 36 months.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life of this measure is 3 years.[136]

4.1.17 Greenhouse Thermal Curtains

DESCRIPTION

Existing greenhouse construction with polyethlene (PE) roofs allows for significant heat loss overnight. The existing PE roofs cause radiant heat to enter the space during daytime, but also lead to heat loss to outside the structure during the night. This can be addressed using thermal curtains which decrease conduction, convection, and radiation heat losses in greenhouses. Thermal curtains are installed inside the greenhouse and are designed to be placed horizontally above the growing zone within a greenhouse. In addition to retaining heat, thermal curtains are commonly used for shading. Thermal insulating curtains are sheets of fabric that extend above the plant growing zone and span the length of the greenhouse. These curtain barriers can reduce nighttime heat loss by more than 20%.[142] Operation of thermal curtains can be manual or motorized, but must be installed to ensure a tight seal at all connection points.

This measure case is defined as the installation of a single-layer heat curtain with infrared film in a greenhouse area in which a heat curtain was not present. It is assumed that the thermal curtains are deployed during nighttime hours, and open during daytime hours. This measure was developed to be applicable to the following program types: NC, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure case is defined as the installation of a single-layer heat curtain with infrared film in a greenhouse area in which a heat curtain was not present. It is assumed that the thermal curtains are deployed during nighttime hours, and open during daytime hours. They can either be manual or motorized thermal curtains installed in greenhouse constructed of PE glazing.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a greenhouse constructed of PE glazing and no thermal curtain.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure lifetime for greenhouse thermal curtains is 5 years.[143]

DEEMED MEASURE COST

Measure cost for greenhouse thermal curtains is $0.76 per square foot.[144]

Algorithm

CALCULATION OF ENERGY SAVINGS

Energy savings are estimated using EnergyPlus version 9.4 whole-building energy simulation. The greenhouse geometry used in the EnergyPlus model consists of 4 connected bays, each bay with a gable type roof construction, measuring 36 feet wide by 100 feet long. The total conditioned floor area of the modeled greenhouse is 14,210 square feet, and savings are normalized per square foot floor area. The greenhouse is conditioned by gas-fired unit heaters and no cooling system. Greenhouse thermal curtain U values vary depending on the material type like

[142] Sanford, Scott, College of Agricultural and Life Science, University of Wisconsin Cooperative Extension. *Using Greenhouse Curtains to Reduce Greenhouse Heating and Cooling Costs.*
[143] DEER 2014, https://cedars.sound-data.com/deer-resources/
[144] Itron, Inc. 2014. *2010-2012 WO017 Ex Ante Measure Cost Study Final Report*. Prepared for the California Public Utilities Commission.

spunbonded polyester, double-knit cloth, aluminized vinyl, aluminum strips, etc. They can have U values as low as 0.26 up to as high as 0.77. However, an average case of 0.483 U value has been simulated here which is assumed to represent a majority of thermal curtains.[145] The area of the thermal curtain equals the conditioned floor area of the greenhouse.

Baseline and efficient models were developed for each Illinois climate zone using inputs for key greenhouse construction characteristics and sources as listed in the following table:

Retrofit:

Input Parameter	Baseline Value	Efficient Value
Roof Glazing	Double PE film, U-value 0.7 ($Btu/h \cdot ft^2 \cdot °F$)[146]	Same as baseline.
Thermal Curtain	None.	Sunset - Sunrise, U-value 0.483 ($Btu/h \cdot ft^2 \cdot °F$)[147]
Wall Glazing	Single PE film, U-value 1.1 ($Btu/h \cdot ft^2 \cdot °F$)[148]	Same as baseline.
Infiltration	1.5 Air Change per Hour (ACH)[149]	Same as baseline.
Ventilation	10 cubic feet per minute (CFM) per area (ft^2)[150]	Same as baseline.
Heating System	Gas-fired unit heater, 0.8 efficiency	Same as baseline.
Thermostat Setpoint	Heating setpoint 70°F	Same as baseline.
Cooling System	Natural Ventilation	Same as baseline.
Occupancy Schedule	8am – 4pm	Same as baseline.
Lighting Power Density	1.83 watts per square foot[151]	Same as baseline.
Lighting Schedule	Varies monthly based on available daylight hours, supplemental lighting operates between 5 – 11 hours per day to target 20 total light hours.[152]	Same as baseline.

New Construction:[153]

4.1.18 Infrared Film for Greenhouse

DESCRIPTION

Existing greenhouse construction with polyethlene (PE) roofs allows for heat transmission loss up to 50%[154]. The existing PE roofs cause radiant heat to enter the space during daytime, but also lead to heat loss to the outside during the night. This issue can be addressed using Infrared-treated (IR) films. They can be applied on the interior side of the PE roof, reducing heat loss through the roof overnight by absorbing and re-emitting infrared radiation and can reduce heat loss by up to 20%.[155] Reduction in heat loss through the roof overnight reduces the heating load on the greenhouse heating system. This measure applies to greenhouses with polyethlene roof construction.

This measure case is defined as a greenhouse roof with infrared (IR) inhibiting film additive on the inflated double polyethylene roof. This measure was developed to be applicable to the following program types: NC, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is infrared film installed on the interior of a PE roof glazing in a gas-heated greenhouse. The recommendation is to use one layer of IR film placed as the inner layer of the roof glazing. Doing this allows the wetting agent that is also included in most films to conduct the condensed moisture away.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a gas-heated greenhouse with PE roof glazing construction and no infrared film.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure lifetime for infrared film is 5 years.[156]

DEEMED MEASURE COST

Incremental cost for IR films installed in new/retrofit applications is $0.02 per square foot of IR film.[157]

Algorithm

CALCULATION OF ENERGY SAVINGS

Energy savings are estimated using EnergyPlus version 9.4 whole-building energy simulation. The greenhouse geometry used in the EnergyPlus model consists of 4 connected bays, each bay with a gable type roof construction, measuring 36 feet wide by 100 feet long. The total conditioned floor area of the modeled greenhouse is 14,210 square feet, and savings are normalized per square foot of conditioned floor area. The greenhouse is conditioned by gas-fired unit heaters and has no dedicated cooling system. Cooling is typically achieved by natural ventilation and exhaust/ventilations fans in the greenhouse space.

[154] Bartok, John, Department of Natural Resources Management and Engineering, University of Connecticut, Natural Resource, Agriculture, and Engineering Service (NRAES) Cooperative Extension, *Energy Conservation for Commercial Greenhouses*, 2001 Revision, Chapter 1, page 4.

[157] Itron, Inc. 2014. *2010-2012 WO017 Ex Ante Measure Cost Study Final Report*. Prepared for the California Public Utilities Commission.

Baseline and efficient models were developed for each Illinois climate zone using inputs for key greenhouse construction characteristics and sources as listed in the following table:

Retrofit:

Input Parameter	Baseline Value	Efficient Value
Roof Glazing	Double PE film, U-value 0.7 ($Btu/h \cdot ft^2 \cdot °F$)[158]	IR-treated double PE film, U-value 0.5 ($Btu/h \cdot ft^2 \cdot °F$) [159]
Wall Glazing	Single PE film, U-value 1.1 ($Btu/h \cdot ft^2 \cdot °F$)[160]	Same as baseline.
Infiltration	1.5 Air Change per Hour (ACH)[161]	Same as baseline.
Ventilation	10 cubic feet per minute (CFM) per area (ft^2)[162]	Same as baseline.
Heating System	Gas-fired unit heater, 0.8 efficiency	Same as baseline.
Thermostat Setpoint	Heating setpoint 70°F	Same as baseline.
Cooling System	Natural Ventilation	Same as baseline.
Occupancy Schedule	8am – 4pm	Same as baseline.
Lighting Power Density	1.83 watts per square foot[163]	Same as baseline.
Lighting Schedule	Varies monthly based on available daylight hours, supplemental lighting operates between 5 – 11 hours per day to target 20 total light hours.[164]	Same as baseline.

New Construction:[165]

Input Parameter	Baseline Value	Efficient Value
Roof Glazing	Double PE film, U-value 0.5 ($Btu/h \cdot ft^2 \cdot °F$)	IR-treated double PE film, U-value 0.3 ($Btu/h \cdot ft^2 \cdot °F$)
Wall Glazing	Double PE film, U-value 0.7 ($Btu/h \cdot ft^2 \cdot °F$)	Same as baseline.
Infiltration	1.5 Air Change per Hour (ACH)	Same as baseline.
Ventilation	10 cubic feet per minute (CFM) per area (ft^2)	Same as baseline.
Heating System	Gas-fired unit heater, 0.8 efficiency	Same as baseline.

[164] ASHRAE ch. 25.2.2 Table 10, Suggested Radiant Energy, Duration, and Time of Day for Supplemental Lighting in Greenhouses, average of all hours.
[165] New construction greenhouses are compliant with IECC 2021 thermal envelope requirements. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Input Parameter	Baseline Value	Efficient Value
Thermostat Setpoint	Heating setpoint 70°F	Same as baseline.
Cooling System	Natural Ventilation	Same as baseline.
Occupancy Schedule	8am – 4pm	Same as baseline.
Lighting Power Density	1.83 watts per square foot	Same as baseline.
Lighting Schedule	Varies monthly based on available daylight hours, supplemental lighting operates between 5 – 11 hours per day to target 20 total light hours.	Same as baseline.

ELECTRIC ENERGY SAVINGS

N/A

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

Natural gas savings are presented for each climate zone per square foot of greenhouse floor area, which constitutes all floor space under the thermal curtains, including pathways and growing canopy.

Zone	Retrofit Therm Savings per Square Foot of Floor Area	NC Therms Savings per Square Foot of Floor Area
Rockford	0.256	0.314
Chicago	0.232	0.285
Springfield	0.206	0.253
Belleville	0.198	0.245
Marion	0.163	0.212

For example**,** a 15,000 sq.ft greenhouse located in Chicago is retrofitting its roof glazing material with an infrared film. The annual savings for the installation will be computed as:

$$\Delta Therms = 15{,}000 * 0.232$$

$$= 3{,}480 \text{ therms.}$$

MEASURE CODE: CI-AGE-GFILM-V02-250101

REVIEW DEADLINE: 1/1/2028

4.1.19 ENERGY STAR Dairy Water Heater

DESCRIPTION

This measure is for upgrading from federal minimum code efficiency to an ENERGY STAR[166] commercial or residential high efficiency water heater on a dairy farm. Water heaters may have a tank for water storage or may be instantaneous. For electric water heaters to be certified by ENERGY STAR, heat pump technology is required. Energy performance of residential water heaters is typically measured by Uniform Energy Factor (UEF) [large sizes are measured by Energy Factor (EF)], gas commercial water heaters are rated by Thermal Efficiency (E_t), and electric commercial water heaters are rated by Coefficient of Performance (COP).

DEFINITION OF EFFICIENT EQUIPMENT

The high efficiency equipment must meet ENERGY STAR specifications.[167]

DEFINITION OF BASELINE EQUIPMENT

Time of sale: The baseline condition is assumed to be a new standard water heater of the same type and service (residential, commercial) as the existing unit being replaced. The new equipment must exceed federal standard efficiency based on equipment type, size category, and subcategory/rating condition.

New Construction: The baseline condition is a new standard water heater of the same type as the efficient, meeting the IECC code level in place at the time the building permit was issued. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints. Note, IECC 2021 became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code

For dairies, efficiency requirements assume a high draw pattern.

Service Type	Equipment Type	Size Category	Federal Minimum Efficiency Requirements[168]
Residential	Gas-Fired Storage Water Heater ≤75,000 Btu/h	≥20 gal and ≤55 gal	UEF = 0.6920 – 0.0013 × V_r
		>55 gal and ≤100 gal	UEF = 0.8072 – 0.0003 × V_r
		> 100 gal	EF = 0.6200 – 0.0019 × V_r
	Gas Fired Instantaneous Water Heater	< 2 gal and > 50,000 Btu/h	UEF = 0.81
	Electric Storage Water Heater	≥20 gal and ≤55 gal	UEF = 0.9349 – 0.0001 × V_r
		>55 gal and ≤120 gal	UEF = 2.2418−0.0011 × Vr
		> 120 gal	EF = 0.9300−0.00132 × Vr
Residential-duty Commercial	High Capacity Storage Gas-Fired Storage Water Heaters > 75,000 Btu/h	≤120 gallon tanks	UEF = 0.6597 – (0.0009 * Vr
Commercial	Gas Storage	Any	80% E_t
	Gas Instantaneous	Any	80% E_t
	Electric Storage	Any	2.18 COP

[166] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[167] ENERGY STAR Program Requirements for Product Specification for Residential Water Heaters, v5.0, effective April 18, 2023. ENERGY STAR Program Requirements Product Specification for Commercial Water Heaters, v2.0, effective October 1, 2018.

[168] Minimum performance rating assumes a high usage draw pattern of 84 gallons per day. A typical dairy in Illinois is estimated to use 131.7 gallons of hot water per day. Please see '4.1.10 Dairy Refrigeration Heat Recovery' for the derivation of the hot water heated on an average dairy farm. Note that minimum performance requirements for residential water heaters toggle between EF and UEF depending on size category based on 'Code of Federal Regulations, federal standards for residential water heaters, 10 CFR 432.32(d)'. Commercial water heaters must meet a minimum Thermal Efficiency (TE) and are subject to

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years for storage units, 20 years for tankless water heaters.[169]

DEEMED MEASURE COST

The full install cost and incremental cost assumptions are provided below.[170] Actual costs should be used where available:

Equipment Type	Category	Installed Cost	Incremental Cost
Gas Storage Water Heaters ≥ 75,000 Btu/hr, ≤55 gallons	Baseline	$616	N/A
	Efficient	$1,055	$440
Gas Storage Water Heaters > 75,000 Btuh/h	80% E_t	$4,886	N/A
	83% E_t	$5,106	$220
	84% E_t	$5,299	$413
	85% E_t	$5,415	$529
	86% E_t	$5,532	$646
	87% E_t	$5,648	$762
	88% E_t	$5,765	$879
	89% E_t	$5,882	$996
	90% E_t	$6,021	$1,135
Electric Storage Water Heaters	50 gallons		$1,050
	80 gallons		$1,050
	100 gallons		$1,950

LOADSHAPE

For electric hot water heaters, use Loadshape C02 – Commercial Electric DHW.

COINCIDENCE FACTOR

The coincidence factor is assumed to be 0.925.[171]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Electric energy savings are calculated for electric water heaters per the equations given below.

maximum standby loss requirements of Q/800 + 110 x $\sqrt{V_r}$ where Q is the input rating in Btu/hr per '2019 Building Energy Efficiency Standards; 5.3 Mandatory Requirements for Water Heating', California Energy Commission.

[169] Additional reference stating >20 years from the US DOE Energy Savers for Tankless or Demand-Type Water Heaters, and 15 years from the 'New York Standard Approach for Estimating Energy Savings from Energy Efficiency Programs', v8.0, effective January 1, 2021.

[170] From the 2010-2012 WO017 Ex Ante Measure Cost Study Final Report from the California Public Utilities Commission Table 3-12.

[171] Coincidence factor based on the average wattage in peak period divided by the maximum wattage from Itron eShape data for Missouri, calibrated to Illinois loads.

$$\Delta kWh = \frac{(T_{OUT} - T_{IN}) * HotWaterUse_{Gallon} * \gamma Water * 1 * \left(\frac{1}{UEF_{elecbase}} - \frac{1}{UEF_{Eff}}\right)}{3412}$$

Where:

T_{OUT} = Tank Temperature

= 170°F [172]

T_{IN} = Incoming water temperature from well or municipal system or other[173]

= Take measurement if possible, otherwise use the following assumptions.

= 52.3°F, average well water temperature if no Dairy Refrigeration Heat Recovery system installed

= 120°F, if Dairy Refrigeration Heat Recovery system is operational

= 86°F, if unknown[174]

$HotWaterUse_{Gallon}$ = Estimated annual hot water consumption (gallons)

= Actual if possible to provide reasonable custom estimate. If not, use the following formula:

= GPD * 365

GPD = average gallons of hot water usage per day (=1.30 gallons per cow per day[175]) * Number of Milking Cows being served by the water heater

γWater = Density of Water (lb/gal)

= 8.33 lbs/gal

1 = Specific Heat of Water (Btu/lb°F)

$UEF_{elecbase}$ = Rated efficiency of baseline water heater expressed as Uniform Energy Factor (UEF)

UEF_{eff} = Rated efficiency of the efficient water heater expressed as Uniform Energy Factor (UEF)

= Actual per ENERGY STAR certified equipment product list

3412 = Converts Btu to kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh}{Hours} * CF$$

Where:

[172] Water heating temperature for dairy farms: The cycle for cleaning needs 170 °F to start and cannot drop below 120°F by the end of the wash cycle. 'Hot Water for Dairy Farms', PHCP Pros, Harvey Ramer, May 11, 2017

[173] Expected temperature a refrigeration heat recovery unit can pre-heat well water up to. For more detail, please see: '4.1.10 Dairy Refrigeration Heat Recovery.'

[174] Average value assuming 50% of farms have Dairy Refrigeration Heat Recovery system

[175] '4.1.10 Dairy Refrigeration Heat Recovery' details average default values for hot water use and number of milking cows if unknown. The 1.30 gallons of hot water per day is calculated from (131.7 GPD/101 cows). This value is corroborated by milking system washing hot water consumption of 5L per cow (1.32 gallons per cow) per Shortall J. et al. and supported by data from NYSERDA Dairy Farm Audit Summary, in which 10 dairy farms averaged of 1.40 gallons of hot water per cow per day based on measured electric water heater energy consumption and assumed 98% efficiency.

Hours = Full load hours of water heater[176]

= 6,461

CF = Summer Peak Coincidence Factor for measure

= 0.925[177]

For example, a residential ENERGY STAR water heater of 100 gallons rated capacity and UEF of 3.5 will be serving hot water to 101 cows milked daily. The farm does not currently have any dairy refrigeration heat recovery system so they are directly getting the water from a well and heating it to 170°F to clean the milking equipment.

$$\Delta kWh = \frac{(T_{OUT} - T_{IN}) * HotWaterUse_{Gallon} * \gamma Water * 1 * \left(\frac{1}{UEF_{elecbase}} - \frac{1}{UEF_{Eff}}\right)}{3{,}412}$$

$$\Delta kWh = \frac{(170\,°\text{F} - 52.3\,°\text{F}) * 101\ cows * \frac{1.30\frac{gal}{cow}}{day} * 8.33\frac{lb}{gal} * 1\frac{Btu}{lb°F} * \left(\frac{1}{(2.2418 - 0.0011 \times 100)} - \frac{1}{3.5}\right)}{3{,}412\frac{Btu}{kWh}} * 365\frac{days}{yr}$$

$$= 2{,}527\ kWh$$

For Demand Saving:

$$\Delta kW = \frac{\Delta kWh}{Hours} * CF$$

$$\Delta kW = \frac{2{,}527}{6{,}461} * 0.925 = 0.36\ kW$$

FOSSIL FUEL SAVINGS

Natural gas energy savings are calculated for natural gas storage water heaters per the equations given below.

$$\Delta Therms = \frac{(T_{out} - T_{in}) * HotWaterUse_{Gallon} * \gamma Water * 1 * \left(\frac{1}{UEF_{gasbase}} - \frac{1}{UEF_{Eff}}\right)}{100{,}000}$$

Where:

100,000 = Converts Btu to Therms

[176] Full load hours assumption based on Wh/Max W Ratio from Itron eShape data for Missouri, calibrated to Illinois loads.
[177] Coincidence factor based on Average W in peak period/Max W from Itron eShape data for Missouri, calibrated to Illinois loads.

$UEF_{gasbase}$ = Rated efficiency of baseline water heater (Expressed as Uniform Energy Factor (UEF).

For example, a 150,000 Btu/h gas storage water heater of 100 gallons rated volume and UEF of 0.9 delivers hot water for 101 cows milked daily. The farm has a dairy refrigeration heat recovery system that supplies 120 °F water to the heater. The farm uses 170°F hot water for milking equipment cleaning.

$$\Delta Therms = \frac{(T_{OUT} - T_{IN}) \times HotWaterUse_{Gallon} \times \gamma Water \times 1 \times \left(\frac{1}{UEF_{gasbase}} - \frac{1}{UEF_{Eff}}\right)}{100{,}000 \frac{Btu}{therm}}$$

$$(170 - 120)°\text{F} \times 101\ cows \times \frac{1.30 \frac{gal}{cow}}{day} \times 365 \frac{days}{yr} \times 8.33 \frac{lb}{gal}$$

$$\Delta Therms = \frac{\times 1 \frac{Btu}{lb°\text{F}} \times \left(\frac{1}{0.8072 - 0.0003 \times 100} - \frac{1}{0.9}\right)}{100{,}000 \frac{Btu}{Therm}} \times 365 \frac{Days}{yr}$$

$$\Delta Therms = 35\ Therms$$

MEASURE CODE: CI-AGE-ESWH-V05-260101

REVIEW DEADLINE: 1/1/2028

4.1.20 Commercial Electric Lawn Mower

DESCRIPTION

This measure identifies the claimed savings associated with commercial lawn mower electrification. This measure was developed to be applicable to the following program types: TOS.

Time of Sale (TOS):

- The use of all-electric equipment in place of a device with a spark-ignition gasoline-powered engine.
- Note that the baseline in this case is an equivalent replacement system to that which exists currently in the business.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is an all-electric lawn mower sized to be equivalent to the baseline gasoline-powered mower.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a new gasoline-powered lawn mower.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life varies based on the equipment type (displayed in the table below).

Equipment Type	Measure Life (years)[178]
Riding Lawn Mower	10
Push Lawn Mower	10

DEEMED MEASURE COST

For Time of Sale (TOS) the incremental cost should be used. Actual costs can also be used although care should be taken as costs can vary significantly. Defaults are provided below.

Equipment Type	Incremental Cost[179]
Riding Lawn Mower	$21,373
Push Lawn Mower	$500

LOADSHAPE

Loadshape C03 – Commercial Cooling[180]

COINCIDENCE FACTOR

The summer Peak Coincidence Factor is assumed to be 91.3%.[181]

[178] Conservative estimate given lack of definitive source. Useful life for commercial gasoline-powered mowers is 5 years, per CARB (2022). CCI Emission Factor Database, "Fuel-Specific GHG" worksheet, available at cci_emissionfactordatabase_2022-11-30.xlsx (live.com). Electric mowers may last significantly longer. Manufacturers estimate 3,000-5,000 hours for electric mowers, according to The Electric Advantage - MEAN GREEN MOWERS (meangreenproducts.com), which equates to more than 10 years at 246 hours per year.

[179] Vermont Act 56 Tier III Technical Advisory Group 2021 ANNUAL REPORT

[180] Commercial cooling loadshape is used as an estimate of likely usage pattern for electric lawn equipment. This methodology is used in other jurisdictions offering electric lawn care equipment savings.

[181] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS

Fuel switch measure (baseline is gas equipment):

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

ΔSiteEnergySavings (MMBtu) $= [GasConsumptionReplaced] - [ElectricConsumptionAdded]$

$=[Fuel_{baseline} * 120{,}238/1{,}000{,}000] - [Fuel_{baseline} * ED_{gasoline} / (ED_{electricity} * EER_{G \to E}) * 3{,}412/1{,}000{,}000]$

$\text{Fuel}_{\text{baseline}}$ $=(BSFC_{baseline} * hp_{baseline} * LF_{baseline} * Hours) / (Fuel\ Density_{gasoline})$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:

$\text{BSFC}_{\text{baseline}}$ = Brake Specific Fuel (Gasoline) Consumption Factor (lbs/hp-hr)

= If unknown, use default values in the table below

$\text{hp}_{\text{baseline}}$ = Horsepower of the lawn mower

= If unknown, use default values in the table below

$\text{LF}_{\text{baseline}}$ = The load factor is the average operational level of an engine as a fraction or percentage of the engine manufacturer's maximum rated horsepower. Load factor is diffcicult to characterize since it is a strong function of the equipment use and operation. Load factors for various equipment types are presented in the table below.

Hours = Annual operating hours of the lawn mower.

= Values for various equipment types are presented in the table below.

$\text{Fuel Density}_{\text{gasoline}}$ = Gasoline fuel density (assume 6.15 lbs/gal)[182]

$\text{ED}_{\text{gasoline}}$ = Energy density of gasoline (assume 115.83 MJ/gal)[182]

$\text{ED}_{\text{electricity}}$ = Energy density of electricity = 3.6 MJ/kWh

$EER_{G \to E}$ = Energy Economy Ratio = 3.4 (for switching from gasoline to electricity)[183]

120,238 = Btu content in one gallon of finished gasoline[184]

1,000,000 = Btu to MMBtu conversion

Equipment Type	$\text{BSFC}_{\text{baseline}}$ (lbs/hp-hr)[186]	$\text{hp}_{\text{baseline}}$[186]	$\text{LF}_{\text{baseline}}$[185]	Hours (hrs/year)	ΔkWh	ΔMMBtu	Site Energy Savings (MMBtu)
Riding Lawn Mower	0.775	21.4	38%	246	-2386	30.3	22.2
Push Lawn Mower	0.789	3.9	33%	161.6	-253	3.2	2.3

For example, using the default assumptions on the application of a riding lawn mower:

$\text{Fuel}_{\text{baseline}}$ = (0.775 * 21.4 * 0.38 * 246) / 6.15

= 252.09

SiteEnergySavings (MMBtu) = (252.09 * 120,238/1,000,000) - (252.09 * 115.83/(3.6 * 3.4) * 3,412 /1,000,000)

= 22.2 MMBtu

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta\text{kW} = -1 * \text{kW}_{\text{battery draw}} * \text{CF}$$

Where:

$\text{kW}_{\text{battery draw}}$ = The electric draw by the battery during charging. This varies based on the battery and charger specifications. If unknown use values in the table below.

Equipment Type	$\text{kW}_{\text{battery draw}}$
Riding Lawn Mower	1.12[186]

[182] CARB (2022). CCI Emission Factor Database, "Fuel-Specific GHG" worksheet, available at cci_emissionfactordatabase_2022-11-30.xlsx (live.com).

[183] Energy Economy Ratio (EER) dimensionless value that represents the efficiency of a fuel as used in a powertrain as compared to a reference fuel used in the same powertrain. [187] Massachusetts Residential Baseline Study, Guidehouse, 2020

[188] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

4.1.21 Indoor Agriculture Dehumidifier

DESCRIPTION

Packaged stand-alone dehumidifiers have become common in indoor agriculture facilities and are used to maintain desirable growing conditions. Dehumidifiers help maintain optimal humidity levels while reducing energy costs.

This measure reduces the demand on air conditioning or other cooling systems, resulting in energy savings. This measure is designed for the installation of packaged stand-alone dehumidifiers for use in indoor agricultural facilities. The savings and costs for this measure are evaluated with the replacement of an existing packaged stand-alone dehumidifier or new construction. Residential and commercial buildings are not eligible.

This measure was developed to be applicable to the following program types: TOS, EREP, and NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the installed dehumidification equipment must meet or exceed 3.0 L/kWh. The efficient equipment is to be rated at 80 degrees F dry bulb temperature and 60% relative humidity.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an installed, stand-alone, non-portable dehumidifier that meets an efficiency of 2.1 liters/kWh at a rated condition of 80 F and 60% relative humidity for projects replacing existing equipment or 2.9 liters/kWh at a rated condition of 80 F and 60% relative humidity for new construction projects. The deemed standard efficiency value is based on manufacturer performance information as found during a December 2021 survey of packaged commercial and industrial dehumidifiers. The deemed high efficiency value is based on manufacturer performance information as found during a December 2021 survey of packaged commercial and industrial dehumidifiers.[189]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years.[190]

DEEMED MEASURE COST

The average incremental cost per capacity (pints per day) is $7.35.[191]

LOADSHAPE

Loadshape C65 – Non-Residential Indoor Agriculture Vegetative Room

Loadshape C66 – Non-Residential Indoor Agriculture Flowering Room

COINCIDENCE FACTOR

The coincidence factor is assumed to be 1 since the dehumidification will always be running during peak periods.[192]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = \text{Capacity} * 0.473 * \text{Hours} * \text{DC} * \left(\frac{1}{\text{Eff}_{\text{Base}}} - \frac{1}{\text{Eff}_{\text{Proposed}}}\right) * \frac{1}{24}$$

Where:

Capacity	= Water removal capacity of the equipment in pints/day rated at 80F and 60% RH
	= Actual installed
0.473	= Constant to convert Pints to Liters
Hours	= Run hours per year
	= 8760 hours
DC	= Duty cycle of the dehumidifier, representing the percentage of time the dehumidifier is actively running
	= 77%[193]
Eff_{Base}	= Actual or 2.1 L/kWh for projects replacing existing equipment or 2.9 L/kWh for new construction. If unknown, assume 2.9 L/kWh.
$\text{Eff}_{\text{Proposed}}$	= Actual energy Factor (L/kWh) of the new high efficiency unit rated at 80F and 60% RH. If unknown, assume 3.0 L/kWh.
24	= Constant to convert Liters/day to Liters/hour.

Existing Equipment:
For example, for the installation of a dehumidifier with 746 Pints/Day water removal at 80F and 60% RH and an Energy Factor of 3.5 L/kWh at 80F and 60% RH that is replacing an existing dehumidifier:

$$\Delta\text{kWh} = 746 * 0.473 * 8760 * 0.77 * \left(\frac{1}{2.1} - \frac{1}{3.5}\right) * \frac{1}{24}$$

$$\Delta\text{kWh} = 18{,}890 \text{ kWh}$$

New Construction:
For example, for the installation of a dehumidifier with 746 Pints/Day water removal at 80F and 60% RH and an Energy Factor of 3.5 L/kWh at 80F and 60% RH that is not replacing an existing dehumidifier:

$$\Delta\text{kWh} = 746 * 0.473 * 8760 * 0.77 * \left(\frac{1}{2.9} - \frac{1}{3.5}\right) * \frac{1}{24}$$

$$\Delta\text{kWh} = 5{,}852 \text{ kWh}$$

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta\text{kW} = \frac{\text{kWh}}{\text{Hours}} * \text{CF}$$

Where:

[193] Energy Trust of Oregon, Measure Approval Document for Indoor Ag Dehumidifiers, November 9, 2023

CF = 1.0

For example, for the installation of a dehumidifier with 746 Pints/Day water removal at 80F and 60% RH and an Energy Factor of 3.5 L/kWh at 80F and 60% RH that is replacing an existing dehumidifier:

$$\Delta\text{kW} = \frac{18{,}969.6}{8760} * 1.0$$

$$\Delta\text{kW} = 2.165 \text{ kW}$$

MEASURE CODE: CI-AGE-DEHU-V01-260101

REVIEW DEADLINE: 1/1/2029

4.2. Food Service End Use

4.2.1 Combination Oven

DESCRIPTION

This measure applies to both natural gas fired and electric high efficiency combination convection and steam ovens installed in a commercial kitchen.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the installed equipment must be a new natural gas or electric combination oven meeting the ENERGY STAR idle rate and cooking efficiency requirements as specified below.[194]

ENERGY STAR[195] Requirements (Version 3.0, Effective January 12, 2023)

Fuel Type	Operation	Idle Rate (Btu/h for Gas, kW for Electric)	Cooking-Energy Efficiency, (%)
Natural Gas (5-40 Pan Capacity)	Steam Mode Convection Mode	≤ 200P+6,511 ≤ 140P+3,800	≥ 41 ≥ 57
Electric (5-40 Pan Capacity)	Steam Mode Convection Mode	≤ 0.133P+0.6400 ≤ 0.083P+0.35	≥ 55 ≥ 78
Electric (3-4 Pan Capacity)	Steam Mode Convection Mode	≤ 0.60P ≤ 0.05P+0.55	≥ 51 ≥ 70

Note: P = Pan capacity as defined in Section 1.Y, of the Commercial Ovens Program Requirements Version 3.0[196]

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a natural gas or electric combination oven that is not ENERGY STAR certified.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years.[197]

DEEMED MEASURE COST

The costs vary based on the efficiency and make of the equipment. Actual costs should be used. Otherwise[198]:

Oven Type & Capacity	Baseline Cost	Efficient Cost	Incremental Measure Cost
Electric < 15 Pan Capacity	$13,919	$16,189	$2,269
Electric 15 – 30 Pan Capacity	$18,966	$21,247	$2,281
Electric > 30 Pan Capacity	$30,827	$34,625	$3,798
Gas < 15 Pan Capacity	$15,406	$19,338	$3,932
Gas 15 – 30 Pan Capacity	$20,292	$24,509	$4,217
Gas > 30 Pan Capacity	$32,508	$38,337	$5,829

[194] ENERGY STAR Commercial Ovens Key Product Criteria, version 3.0, effective January 12, 2023

[195] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[196] Ibid. Pan capacity is defined as the number of steam table pans the combination oven is able to accommodate as per the ASTM F-1495-05 standard specification.

[197] The measure life is sourced from the Food Service Technology Center's energy savings calculator for combination ovens.

[198] Costs are sourced from Food Service Technology Center 2016 'Combi_2016_Prices_Updated' which is also used in the ENERGY STAR Commercial Foodservice Savings Calculator, published March, 2021.

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

Summer Peak Coincidence Factor for measure is assumed to be 0.90.[199]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS[200]

Non-Fuel Switch Measures

The algorithm below applies to electric combination ovens only.

$$\Delta kWh = (\Delta CookingEnergy_{ConvElec} + \Delta CookingEnergy_{SteamElec} + \Delta IdleEnergy_{ConvElec} + \Delta IdleEnergy_{SteamElec} + \Delta PreHeatEnergy_{Elec}) * Days / 1{,}000$$

The algorithm below applies to natural gas combination ovens only.

$$\Delta Therms = (\Delta CookingEnergy_{ConvGas} + \Delta CookingEnergy_{SteamGas} + \Delta IdleEnergy_{ConvGas} + \Delta IdleEnergy_{SteamGas} + \Delta PreHeatEnergy_{Gas}) * Days / 100{,}000$$

Fuel Switch/Electrification Measures

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

$$\text{SiteEnergySavings (MMBTUs)} = [GasConsumptionReplaced] - [ElectricConsumptionAdded]$$

$$= [(CookingEnergy_{ConvGasBase} + CookingEnergy_{SteamGasBase} + IdleEnergy_{ConvGasBase} + IdleEnergy_{SteamGasBase} + PreHeatEnergy_{BaseGas}) * Days / 1{,}000{,}000] -$$

$$[(CookingEnergy_{ConvElecEE} + CookingEnergy_{SteamElecEE} + IdleEnergy_{ConvElecEE} + IdleEnergySteam_{ElecEE} + PreHeatEnergy_{EEElec}) * Days * 3.412 / 1{,}000{,}000]$$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A

[199] Itron, Inc. 2005. 2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report. Prepared for Southern California Edison.

[200] Algorithms and assumptions derived from ENERGY STAR Commercial Kitchen Equipment Savings Calculator, updated March 2021.

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:

ΔCookingEnergy$_{ConvElec}$ = Change in total daily cooking energy consumed by electric oven in convection mode

$=LB_{Elec} * (EFOOD_{ConvElec} / ElecEFF_{ConvBase} - EFOOD_{ConvElec} / ElecEFF_{ConvEE}) * \%_{Conv}$

ΔCookingEnergy$_{SteamElec}$ = Change in total daily cooking energy consumed by electric oven in steam mode

$=LB_{Elec} * (EFOOD_{SteamElec} / ElecEFF_{SteamBase} - EFOOD_{SteamElec} / ElecEFF_{SteamEE}) * \%_{Steam}$

ΔIdleEnergy$_{ConvElec}$ = Change in total daily idle energy consumed by electric oven in convection mode

$=[(ElecIDLE_{ConvBase} * ((HOURS - LB_{Elec}/ElecPC_{ConvBase}) * \%_{Conv})) - (ElecIDLE_{ConvEE} * ((HOURS - LB_{Elec}/ElecPC_{ConvEE}) * \%_{Conv}))]$

ΔIdleEnergy$_{SteamElec}$ = Change in total daily idle energy consumed by electric oven in steam mode

$=[(ElecIDLE_{SteamBase} * ((HOURS - LB_{Elec}/ElecPC_{SteamBase}) * \%_{Steam})) - (ElecIDLE_{SteamEE} * ((HOURS - LB_{Elec}/ElecPC_{SteamEE}) * \%_{Steam}))]$

ΔPreHeatEnergy$_{Elec}$ = Change in total daily energy consumed by electric oven to preheat

$= Preheat_{BaseElec} - Preheat_{EEElec}$

ΔCookingEnergy$_{ConvGas}$ = Change in total daily cooking energy consumed by gas oven in convection mode

$=LB_{Gas} * (EFOOD_{ConvGas} / GasEFF_{ConvBase} - EFOOD_{ConvGas} / GasEFF_{ConvEE}) * \%_{Conv}$

ΔCookingEnergy$_{SteamGas}$ = Change in total daily cooking energy consumed by gas oven in steam mode

$=LB_{Gas} * (EFOOD_{SteamGas} / GasEFF_{SteamBase} - EFOOD_{SteamGas} / GasEFF_{SteamEE}) * \%_{Steam}$

ΔIdleEnergy$_{ConvGas}$ = Change in total daily idle energy consumed by gas oven in convection mode

$=[(GasIDLE_{ConvBase} * ((HOURS - LB_{Gas}/GasPC_{ConvBase}) * \%_{Conv})) - (GasIDLE_{ConvEE} * ((HOURS - LB_{Gas}/GasPC_{ConvEE}) * \%_{Conv}))]$

ΔIdleEnergy$_{SteamGas}$ = Change in total daily idle energy consumed by gas oven in steam mode

$=[(GasIDLE_{SteamBase} * ((HOURS - LB_{Gas}/GasPC_{SteamBase}) * \%_{Steam})) - (GasIDLE_{SteamEE} * ((HOURS - LB_{Gas}/GasPC_{SteamEE}) * \%_{Steam}))]$

ΔPreHeatEnergy$_{Gas}$ = Change in total daily energy consumed by gas oven to preheat

$= Preheat_{BaseGas} - Preheat_{EEGas}$

CookingEnergy$_{ConvElecEE}$ = Total daily cooking energy consumed by new ENERGY STAR electric oven in convection mode (for fuel switch measure)

$=LB_{Elec} * (EFOOD_{ConvElec} / ElecEFF_{ConvEE}) * \%_{Conv}$

CookingEnergy$_{SteamElecEE}$ = Total daily cooking energy consumed by new ENERGY STAR electric oven in steam mode (for fuel switch measure)

$=LB_{Elec} * (EFOOD_{SteamElec} / ElecEFF_{SteamEE}) * \%_{Steam}$

IdleEnergy$_{ConvElecEE}$ = Total daily idle energy consumed by new ENERGY STAR electric oven in convection mode (for fuel switch measure)

$=(ElecIDLE_{ConvEE} * ((HOURS - LB_{Elec}/ElecPC_{ConvEE}) * \%_{Conv}))$

IdleEnergy$_{SteamElecEE}$ = Total daily idle energy consumed by new ENERGY STAR electric oven in convection mode (for fuel switch measure)

$=(ElecIDLE_{SteamEE} * ((HOURS - LB_{Elec}/ElecPC_{SteamEE}) * \%_{Steam}))$

CookingEnergy$_{ConvGasBase}$ = Total daily cooking energy consumed by baseline gas oven in convection mode (for fuel switch measure)

$=LB_{Gas} * (EFOOD_{ConvGas} / GasEFF_{ConvBase}) * \%_{Conv}$

CookingEnergy$_{SteamGasBase}$ = Total daily cooking energy consumed by baseline gas oven in steam mode (for fuel switch measure)

$=LB_{Gas} * (EFOOD_{SteamGas} / GasEFF_{SteamBase}) * \%_{Steam}$

IdleEnergy$_{ConvGasBase}$ = Total daily idle energy consumed by baseline gas oven in convection mode (for fuel switch measure)

$=(GasIDLE_{ConvBase} * ((HOURS - LB_{Gas}/GasPC_{ConvBase}) * \%_{Conv}))$

IdleEnergy$_{SteamGasBase}$ = Total daily idle energy consumed by baseline gas oven in convection mode(for fuel switch measure)

$=[(GasIDLE_{SteamBase} * ((HOURS - LB_{Gas}/GasPC_{SteamBase}) * \%_{Steam}))$

Where:

LB_{Elec} = Estimated mass of food cooked per day for electric oven (lbs/day)

= Custom, or if unknown, use 200 lbs (If P <15) or 250 lbs (If P >= 15)

$EFOOD_{ConvElec}$ = Energy absorbed by food product for electric oven in convection mode

= Custom or if unknown, use 73.2 Wh/lb

ElecEFF = Cooking energy efficiency of electric oven

= Custom or if unknown, use values from table below

	Base	EE
$ElecEFF_{Conv}$	72%	78%
$ElecEFF_{Steam}$	52%	55%

$\%_{Conv}$ = Percentage of time in convection mode

= Custom or if unknown, use 50%

$EFOOD_{SteamElec}$ = Energy absorbed by food product for electric oven in steam mode

= Custom or if unknown, use 30.8 Wh/lb

$\%_{steam}$ = Percentage of time in steam mode

= 1 - $\%_{conv}$

$ElecIDLE_{Base}$ = Idle energy rate (W) of baseline electric oven

= Custom or if unknown, use values from table below

Pan Capacity	Convection Mode ($ElecIDLE_{ConvBase}$)	Steam Mode ($ElecIDLE_{SteamBase}$)
< 15	1,754	5,260
> = 15 to <30	2,966	8,866
>= 30	4,418	11,875

HOURS = Average daily hours of operation

= Custom or if unknown, use 12 hours

$ElecPC_{Base}$ = Production capacity (lbs/hr) of baseline electric oven

= Custom of if unknown, use values from table below

Pan Capacity	Convection Mode ($ElecPC_{ConvBase}$)	Steam Mode ($ElecPC_{SteamBase}$)
< 15	79	126
> = 15	166	295

$ElecIDLE_{ConvEE}$ = Idle energy rate of ENERGY STAR electric oven in convection mode

= Custom or if unknown, use default below:

= (0.083*P +0.350) * 1000 for 5-40 Pan Capacity

= (0.05*P +0.55) * 1000 for 3-4 Pan Capacity

$ElecPC_{EE}$ = Production capacity (lbs/hr) of ENERGY STAR electric oven

= Custom of if unknown, use values from table below

Pan Capacity	Convection Mode ($ElecPC_{ConvEE}$)	Steam Mode ($ElecPC_{SteamEE}$)
< 15	119	177
> = 15	201	349

$ElecIDLE_{SteamEE}$ = Idle energy rate of ENERGY STAR electric oven in steam mode

= Custom or if unknown, use default below:

= (0.133 * P+0.64) * 1000 for 5-40 Pan Capacity

= (0.60 * P) * 1000 for 3-4 Pan Capacity

$Preheat_{BaseElec}$ = Total preheat energy consumption per day of baseline electric unit (Wh)

= Custom or if unknown, use default below:

Pan Capacity	$Preheat_{BaseElec}$
< 15	1,635
> = 15	3,146

$Preheat_{EEElec}$ = Total preheat energy consumption per day of ENERGY STAR electric unit (Wh)

Pan Capacity	$Preheat_{EEElec}$
< 15	997
> = 15	1,633

Days = Days of operation per year

= Custom or if unknown, use 365 days per year

1,000 = Wh to kWh conversion factor

LB_{Gas} = Estimated mass of food cooked per day for gas oven (lbs/day)

= Custom, or if unknown, use 200 lbs (If P <15), 250 lbs (If 15 <= P 30), or 400 lbs (If P = >30)

$EFOOD_{ConvGas}$ = Energy absorbed by food product for gas oven in convection mode

= Custom or if unknown, use 250 Btu/lb

GasEFF = Cooking energy efficiency of gas oven

= Custom or if unknown, use values from table below

	Base	EE
$GasEFF_{Conv}$	49%	57%
$GasEFF_{Steam}$	37%	41%

$EFOOD_{SteamGas}$ = Energy absorbed by food product for gas oven in steam mode

= Custom or if unknown, use 105 Btu/lb

$GasIDLE_{Base}$ = Idle energy rate (Btu/hr) of baseline gas oven

= Custom or if unknown, use values from table below

Pan Capacity	Convection Mode ($GasIDLE_{ConvBase}$)	Steam Mode ($GasIDLE_{SteamBase}$)
< 15	9,840	24,003
15-30	11,734	27,795
>30	15,376	27,957

$GasPC_{Base}$ = Production capacity (lbs/hr) of baseline gas oven

= Custom of if unknown, use values from table below

Pan Capacity	Convection Mode ($GasPC_{ConvBase}$)	Steam Mode ($GasPC_{SteamBase}$)
< 15	125	195
15-30	176	211
>30	392	579

$GasIDLE_{ConvEE}$ = Idle energy rate of ENERGY STAR gas oven in convection mode

= Custom or if unknown, use default below:

= 140*P + 3,800

$GasPC_{EE}$ = Production capacity (lbs/hr) of ENERGY STAR gas oven

= Custom of if unknown, use values from table below

Pan Capacity	Convection Mode ($GasPC_{ConvEE}$)	Steam Mode ($GasPC_{SteamEE}$)
< 15	124	172
15-30	210	277
>30	394	640

$GasIDLE_{SteamEE}$ = Idle energy rate of ENERGY STAR gas oven in steam mode

= Custom or if unknown, use default below:

= 200 * P +6511

$Preheat_{BaseGas}$ = Total preheat energy consumption per day of baseline gas unit (BTU)

= Custom or if unknown, use default below:

Pan Capacity	$Preheat_{BaseGas}$
< 15	10,964
> = 15	15,844

$Preheat_{EEGas}$ = Total preheat energy consumption per day of ENERGY STAR gas unit (BTU)

= Custom or if unknown, use default below:

Pan Capacity	$Preheat_{EEGas}$
< 15	4,467
> = 15	10,638

100,000 = Conversion factor from Btu to therms

3.412 = Conversion factor from Wh to Btu

1,000,000 = Conversion factor from Btu to MMBtu

For example, a 10-pan capacity ENERGY STAR electric combination oven in place of a baseline electric oven would save:

ΔkWh =($\Delta CookingEnergy_{ConvElec} + \Delta CookingEnergy_{SteamElec} + \Delta IdleEnergy_{ConvElec} + \Delta IdleEnergy_{SteamElec} + \Delta PreHeatEnergy_{Elec}) * Days / 1{,}000$

ΔCookingEnergy$_{ConvElec}$ = 200 * (73.2 / 0.72 – 73.2 / 0.78) * 0.50

= 782 Wh

ΔCookingEnergy$_{SteamElec}$ = 200 * (30.8 / 0.52 – 30.8 / 0.55) * (1 – 0.50)

= 323 Wh

ΔIdleEnergy$_{ConvElec}$ = [(1,754 * ((12 – 200/79) * 0.50)) - (1,180 *((12 - 200/119) * 0.50))]

= 2,215 Wh

ΔIdleEnergy$_{SteamElec}$ = [(5,260 * ((12 – 200/126) * (1 – 0.50))) - (1,970 * ((12 - 200/177) * (1 – 0.50)))]

= 16,678 Wh

ΔPreHeatEnergy$_{Elec}$ = 1,635 – 997

= 638 Wh

ΔkWh = (782 + 323 + 2215 + 16,678 + 638) * 365 /1,000

= 7,532 kWh

For example, an ENERGY STAR 10-pan capacity electric combination oven in place of a baseline gas combination oven would save:

SiteEnergySavings (MMBTUs) = $[GasConsumptionReplaced] - [ElectricConsumptionAdded]$

$$=[(CookingEnergy_{ConvGasBase} + CookingEnergy_{SteamGasBase} + IdleEnergy_{ConvGasBase} + IdleEnergy_{SteamGasBase} + PreHeatEnergy_{BaseGas}) * Days / 1{,}000{,}000] - [(CookingEnergy_{ConvElecEE} + CookingEnergy_{SteamElecEE} + IdleEnergy_{ConvElecEE} + IdleEnergy_{SteamElecEE} + PreHeatEnergy_{EEElec}) * Days * 3.412/ 1{,}000{,}000]$$

$CookingEnergy_{ConvGasBase}$ = 200 * (250 / 0.49) * 0.50

=51,020 Btu

$CookingEnergy_{SteamGasBase}$ = 200 * (105 / 0.37) * (1 – 0.50)

= 28,378 Btu

$IdleEnergy_{ConvGasBase}$ = 9,840 * ((12 – 200/125) * 0.50))

= 51,168 Btu

$IdleEnergy_{SteamGasBase}$ = 24,003 * ((12 – 200/195) * (1 – 0.50))

= 131,709 Btu

$PreHeatEnergy_{BaseGas}$ = 10,964 Btu

$CookingEnergy_{ConvElecEE}$ = 200 * (73.2 / 0.78) * 0.50

= 9,385 Wh

$CookingEnergy_{SteamElecEE}$ = 200 * (30.8 / 0.55) * (1 – 0.50)

= 5,600 Wh

$IdleEnergy_{ConvElecEE}$ = 1,180 * ((12 - 200/119) * 0.50)

= 6,088 Wh

$IdleEnergy_{SteamElecEE}$ = 1,970 * ((12 - 200/177) * (1 – 0.50)))

= 10,707 Wh

$PreHeatEnergy_{EEElec}$ = 997 Wh

SiteEnergySavings (MMBTUs) = [(51,020 + 28,378 + 51,168 + 131,709 + 10,964) * 365 /1,000,000] – [(9,385 + 5,600 + 6,088 + 10,707 + 997) * 365 * 3.412/1,000,000]

= 58.9 MMBtu

If supported by an electric utility; ΔkWh = ΔSiteEnergySavings * 1,000,000 / 3,412

= 58.9 * 1,000,000/3,412

= 17,263 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

For non-fuel switch measures:

$$\Delta kW = ((\Delta CookingEnergy_{ConvElec} + \Delta CookingEnergy_{SteamElec} + \Delta IdleEnergy_{ConvElec} + \Delta IdleEnergy_{SteamElec} + \Delta PreHeatEnergy_{Elec}) / (1{,}000 * HOURS) * CF$$

For fuel switch measures:

$$\Delta kW = -((CookingEnergy_{ConvElecEE} + CookingEnergy_{SteamElecEE} + IdleEnergy_{ConvElecEE} + IdleEnergy_{SteamElecEE} + PreHeatEnergy_{EEElec})/(1{,}000 * HOURS) * CF$$

Where:

CF = Summer Peak Coincidence Factor for measure

= 0.90[201]

All other variables as defined above.

For example, a 10-pan capacity electric combination oven in a Full Service Limited Menu restaurant would save:

$\Delta kW = \Delta kWh / (1{,}000 * HOURS) * CF$

= (782 + 323 + 2,215 + 16,678 + 638) / (1,000 * 12) * 0.9

= 1.55 kW

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

$\Delta Therms = [Gas\ Cooking\ Consumption\ Replaced]$

$= [(CookingEnergy_{ConvGasBase} + CookingEnergy_{SteamGasBase} + IdleEnergy_{ConvGasBase} + IdleEnergy_{SteamGasBase} + PreHeatEnergy_{BaseGas}) * Days / 100{,}000]$

$\Delta kWh = [Electric\ Cooking\ Consumption\ Added]$

$= -[(CookingEnergy_{ConvElecEE} + CookingEnergy_{SteamElecEE} + IdleEnergy_{ConvElecEE} + IdleEnergy_{SteamElecEE} + PreHeatEnergy_{EEElec}) * Days/1{,}000]$

MEASURE CODE: CI-FSE-CBOV-V07-260101

REVIEW DEADLINE: 1/1/2028

4.2.2 Commercial Solid and Glass Door Refrigerators & Freezers

DESCRIPTION

This measure relates to the installation of a new reach-in commercial refrigerator or freezer meeting ENERGY STAR[202] efficiency standards. ENERGY STAR labeled commercial refrigerators and freezers are more energy efficient because they are designed with components such as ECM evaporator and condenser fan motors, hot gas anti-sweat heaters, or high-efficiency compressors, which will significantly reduce energy consumption.

This measure was developed to be applicable to the following program types: TOS and NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be a new ENERGY STAR certified vertical closed solid or glass door refrigerator or freezer meeting energy consumptions requirements as determined by door type (solid or glass) and refrigerated volume (V).

ENERGY STAR Requirements (Version 5.0, Effective December 22, 2022)

Volume (ft^3)	Maximum Daily Energy Consumption (kWh/day)	
	Refrigerator	Freezer
Vertical Closed		
Solid Door		
0 < V < 15	≤ 0.0267V + 0.8	≤ 0.21V + 0.9
15 ≤ V < 30	≤ 0.05V + 0.45	≤ 0.12V + 2.248
30 ≤ V < 50	≤ 0.05V + 0.45	≤ 0.2578V -1.8864
V ≥ 50	≤ 0.025V + 1.6991	≤ 0.14V + 4.0
Glass Door		
0 < V < 15	≤ 0.095V + 0.445	≤ 0.232V + 2.36
15 ≤ V < 30	≤ 0.05V + 1.12	
30 ≤ V < 50	≤ 0.076V + 0.34	
V ≥ 50	≤ 0.105V – 1.111	

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline equipment is assumed to be a new vertical closed solid or glass door refrigerator or freezer that is not ENERGY STAR certified.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years. [203]

DEEMED MEASURE COST

The incremental capital cost for this measure is provided in the table below.[204]

[202] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[203] 2008 Database for Energy-Efficiency Resources (DEER), Version 2008.2.05, "Effective/Remaining Useful Life Values", California Public Utilities Commission, December 16, 2008.

[204] Energy Star, 2021. ENERGY STAR Version 5.0 Commercial Refrigerators and Freezers Data Pack.xlsx. From Incremental Cost and Payback tab, an average $/sq ft value was calculated and applied to the average volumes for each refrigerator and freezer category – rounded to the nearest dollar (from product data tabs, and 2023 Energy Star QPL)

Door Type	Volume	Refrigerator	Freezer
Solid Door	0 < V < 15	$53	$27
	15 ≤ V < 30	$121	$57
	30 ≤ V < 50	$247	$119
	50 ≤ V	$401	$196
Glass Door	0 < V < 15	$51	$19
	15 ≤ V < 30	$125	$56
	30 ≤ V < 50	$252	$114
	50 ≤ V	$420	$201

LOADSHAPE

Loadshape C23 - Commercial Refrigeration

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 0.937.[205]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (kWhbase - kWhee) * 365.25$$

Where:

kWhbase = baseline maximum daily energy consumption in kWh

= calculated using actual chilled or frozen compartment volume (V) of the efficient unit as shown in the table below.

Type	kWhbase[206]
Solid Door Refrigerator	0.05 * V + 1.36
Glass Door Refrigerator	0.1 * V + 0.86
Solid Door Freezer	0.22 * V + 1.38
Glass Door Freezer	0.29 * V + 2.95

kWhee[207] = efficient maximum daily energy consumption in kWh

= actual if known. If unknown can be calculated using actual chilled or frozen compartment volume (V) of the efficient unit as shown in the table below.

Volume (ft^3)	kWhee	
	Refrigerator	Freezer
Vertical Closed		
Solid Door		
0 < V < 15	≤ 0.0267V + 0.8	≤ 0.21V + 0.9

[205] The CF for Commercial Refrigeration was calculated based upon the Ameren provided eShapes

[206] Federal standards for equipment manufactured on or after March 27, 2017: 10 CFR §431.66 - Energy Conservation Standards for Commercial Refrigerators, Freezers and Refrigerator-Freezers.

[207] ENERGY STAR Program Requirements for Commercial Refrigerators and Freezers Partner Commitments Version 5.0, effective December 22, 2022

Volume (ft^3)	kWhee	
	Refrigerator	Freezer
15 ≤ V < 30	≤ 0.05V + 0.45	≤ 0.12V + 2.248
30 ≤ V < 50	≤ 0.05V + 0.45	≤ 0.2578V -1.8864
V ≥ 50	≤ 0.025V + 1.6991	≤ 0.14V + 4.0
Glass Door		
0 < V < 15	≤ 0.095V + 0.445	≤ 0.232V + 2.36
15 ≤ V < 30	≤ 0.05V + 1.12	
30 ≤ V < 50	≤ 0.076V + 0.34	
V ≥ 50	≤ 0.105V – 1.111	

V = the chilled or frozen compartment volume (ft^3) (as defined in the Association of Home Appliance Manufacturers Standard HRF1–1979)

= Actual installed

365.25 = days per year

For example, a solid door refrigerator with a volume of 15 would save

ΔkWh = (2.11 – 1.20) * 365.25

= 332 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = $\Delta kWh \; / \; HOURS \; * \; CF$

Where:

HOURS = equipment is assumed to operate continuously, 24 hours per day, 365.25 days per year.

= 8766

CF = Summer Peak Coincidence Factor for measure

= 0.937

For example, a solid door refrigerator with a volume of 15 would save

ΔkW = 332/ 8766 * .937

=0.0355 kW

REVIEW DEADLINE: 1/1/2028

4.2.3 Commercial Steam Cooker

DESCRIPTION

To qualify for this measure the installed equipment must be an ENERGY STAR®[208] steamer in place of a standard steamer in a commercial kitchen. Savings are presented dependent on the pan capacity and corresponding idle rate at heavy load cooking capacity and if the steamer is gas or electric.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be as follows:

Gas	Electric
ENERGY STAR® qualified with 38% minimum cooking energy efficiency at heavy load (potato) cooking capacity for gas steam cookers.	ENERGY STAR® qualified with 50% minimum cooking energy efficiency at heavy load (potato) cooking capacity for electric steam cookers.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is assumed to be a non-ENERGY STAR® commercial steamer at end of life. It is assumed that the efficient equipment and baseline equipment have the same number of pans.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years.[209]

DEEMED MEASURE COST

The incremental capital cost for this measure uses actual costs, otherwise use costs outlined below:[210]

Equipment Type	Baseline Equipment Cost	Efficient Equipment Cost	Incremental Cost
Electric	$5,444	$8,201	$2,758
Gas	$10,265	$12,324	$2,059

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

Summer Peak Coincidence Factor for measure is provided below for different building types:[211]

Location	CF
Fast Food Limited Menu	0.32
Fast Food Expanded Menu	0.41
Pizza	0.46
Full Service Limited Menu	0.51

[208] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[209] California DEER 2008 which is also used by both the Food Service Technology Center and ENERGY STAR®.

:

Algorithm

CALCULATION OF SAVINGS

Formulas below are applicable to both gas and electric steam cookers. Please use appropriate lookup values and identified flags.

ENERGY SAVINGS AND FOSSIL FUEL SAVINGS

Non-Fuel Switch Measures

The algorithm below applies to ENERGY STAR electric steam cooker compared to baseline electric steam cooker:

$$\Delta kWh = (\Delta Idle\ Energy + \Delta Preheat\ Energy + \Delta Cooking\ Energy) * Days$$

The algorithm below applies to ENERGY STAR gas steam cooker compared to baseline gas steam cooker:

$$\Delta Therms = (\Delta Idle\ Energy + \Delta Preheat\ Energy + \Delta Cooking\ Energy) * 1/100{,}000 * Days$$

Fuel Switch/Electrification Measures

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

$$SiteEnergySavings\ (MMBTUs) = [GasConsumptionReplaced] - [ElectricConsumptionAdded]$$

$$= [(Idle\ Energy_{GasBase} + Preheat\ Energy_{GasBase} + Cooking\ Energy_{GasBase}) * 1/1{,}000{,}000 * Days] - [(Idle\ Energy_{ElecEE} + Preheat\ Energy_{ElecEE} + Cooking\ Energy_{ElecEE}) * 3{,}412/1{,}000{,}000 * Days]$$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:

ΔIdle Energy $=((((1 - CSM_{\%Baseline}) * IDLE_{BASE} + CSM_{\%Baseline} * PC_{BASE} * E_{FOOD} / EFF_{BASE}) * (HOURS_{day} - (F / PC_{Base}) - (PRE_{number} * PRE_{TimeBase} / 60))) - (((1 - CSM_{\%ENERGYSTAR}) * IDLE_{ENERGYSTAR} + CSM_{\%ENERGYSTAR} * PC_{ENERGYSTAR} * E_{FOOD} / EFF_{ENERGYSTAR}) * (HOURS_{Day} - (F\,l / PC_{ENERGYSTAR}) - (PRE_{number} * PRE_{TimeEE} / 60))))$

[231]Amount used by both Food Service Technology Center and ENERGY STAR® savings calculator

[232]Reference ENERGY STAR Commercial Kitchen Equipment Savings Calculator, Steam Cooker Calculations.

[233]Ibid.

[234]Ibid.

For example, for an ENERGY STAR gas steam cooker compared to baseline gas cooker: A 3 pan steamer in a full service restaurant

ΔSavings = $(\Delta Idle\ Energy + \Delta Preheat\ Energy + \Delta Cooking\ Energy) * Days * 1/100{,}000$

ΔIdle Energy = $((((1 - 0.9) * 11{,}000 + 0.9 * 65 * 105\ /0.15\ ) * (7 - (100\ /\ 65) - (1 * 10.9/60))) - (((1 - 0) * 6250 + 0 * 55 * 105\ /\ 0.38) * (7 - (100\ /\ 55) - (1 * 13.4/60))))$

= 191,028 BTU/day

ΔPreheat Energy = $(1 * (18{,}832.7 - 10{,}293.9)$

= 8,539 BTU/day

ΔCooking Energy = $(((1/\ 0.15) - (1/\ 0.38)) * (100\ lb/day * 105\ btu/lb)))$

= 42,368 BTU/day

ΔTherms = $(191{,}028 + 8{,}539 + 42{,}368) * 365.25 * 1/100{,}000$

= 884 therms

For an ENERGY STAR electric steam cooker compared to baseline electric cooker: A 3 pan steamer in a cafeteria:

ΔSavings = $(\Delta Idle\ Energy + \Delta Preheat\ Energy + \Delta Cooking\ Energy) * Days$

ΔIdle Energy = $((((1 - .9) * 1.0 + .9 * 70 * 0.0308\ /0.26\ ) * (6 - (100\ /\ 70) - (1 * 11.9/60))) - (((1 - 0) * 0.4 + 0 * 50 * 0.0308\ /\ 0.50) * (6 - (100\ /\ 50) - (1 * 13.2/60))))$

= 31.6 kWh/day

ΔPreheat Energy = $(1 * (1.78 - 1.67\ ))$

= 0.1 kWh/day

ΔCooking Energy = $(((1/\ 0.26) - (1/\ 0.5)) * (100 * 0.0308)))$

= 5.7 kWh/day

ΔkWh = $(31.6 + 0.1 + 5.7) * 365.25\ days$

= 13,660 kWh

For an ENERGY STAR electric steam cooker compared to baseline gas cooker: A 3 pan steamer in a cafeteria:

SiteEnergySavings (MMBTUs) $= [GasConsumptionReplaced] - [ElectricConsumptionAdded]$

$=[(Idle\ Energy_{GasBase} + Preheat\ Energy_{GasBase} + Cooking\ Energy_{GasBase}) * 1/1{,}000{,}000 * Days] - [(Idle\ Energy_{ElecEE} + Preheat\ Energy_{ElecEE} + Cooking\ Energy_{ElecEE}) * 3412/1{,}000{,}000 * Days]$

Idle Energy$_{GasBase}$ $=((((1 - 0.9) * 11000 + 0.9 * 65 * 105\ /0.15\ ) * (6 - (100\ /\ 65) - (1 * 10.9/60)))$

= 187,432 Btu

Preheat Energy$_{GasBase}$ $= (1 * 18{,}832)$

= 18,832 BTU/day

Cooking Energy$_{GasBase}$ $= (1/\ 0.15) * (100\ lb/day * 105\ btu/lb)$

= 70,000 BTU/day

Idle Energy$_{ElecEE}$ $= (((1 - 0) * 0.4 + 0 * 50 * 0.0308\ \ /\ 0.50) * (6 - (100\ /\ 50) - (1 * 13.2/60))))$

= 1.5 kWh/day

Preheat Energy$_{ElecEE}$ $= (1 * 1.67)$

= 1.67 kWh/day

Cooking Energy$_{ElecEE}$ $= (1/\ 0.5) * (100 * 0.0308)$

= 6.16 kWh/day

SiteEnergySavings (MMBTUs) $=[(187{,}432 + 18{,}832 + 70{,}000) * 1/1{,}000{,}000 * 365.25] - [(1.5 + 1.67 + 6.16) * 3{,}412/1{,}000{,}000 * 365.25]$

= 89.3 MMBtu

If supported by an electric utility: ΔkWh $= \Delta SiteEnergySavings * 1{,}000{,}000\ /\ 3{,}412$

$= 89.3 * 1{,}000{,}000/3{,}412$

= 26,172 kWh

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons)\ /\ 1{,}000{,}000\ *\ E_{water\ supply}$$

Where

$E_{water\ supply}$ = IL Supply Energy Factor (kWh/Million Gallons)

=2,571[235]

For example, an electric 3 pan steamer with average efficiency in a full service – expanded menu restaurant

ΔWater (gallons) $= (40 - 10) * 7 * 365.25$

= 76,703 gallons

ΔkWh_{water} $= 76{,}703/1{,}000{,}000 * 2{,}571$

= 197 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

This is only applicable to the electric steam cooker.

Non-fuel switch measures:

$$\Delta kW = ((\Delta Idle\ Energy + \Delta Preheat\ Energy + \Delta Cooking\ Energy)/HOURSDay) * CF$$

$$\Delta kW = -((Idle\ EnergyElecEE + Preheat\ EnergyElecEE + Cooking\ EnergyElecEE)/HOURSDay) * CF$$

Where:

CF =Summer Peak Coincidence Factor for measure is provided below for different locations:[236]

Location	CF
Fast Food Limited Menu	0.32
Fast Food Expanded Menu	0.41
Pizza	0.46
Full Service Limited Menu	0.51
Full Service Expanded Menu	0.36
Cafeteria	0.39
Unknown	0.408

Other values as defined above

For example, for 3 pan electric steam cooker located in a cafeteria:

ΔkW $=((\Delta Idle\ Energy + \Delta Preheat\ Energy + \Delta Cooking\ Energy)/(HOURSDay * Days)) * CF$

$= ((31.18 + 0.5 + 5.69)/6) * 0.39$

$= 2.43\ kW$

[235] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'. Note that the Commercial Steam Cooker does not discharge its water into the wastewater system so only the water supply factor is used here.

[236] Values taken from Minnesota Technical Reference Manual (Version 2.2, effective May 2, 2018), 'Electric Oven and Range' measure and are based upon "Project on Restaurant Energy Performance-End-Use Monitoring and Analysis", Appendixes I and II, Claar, et. al., May 1985.

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

WATER IMPACT DESCRIPTIONS AND CALCULATION

This is applicable to both gas and electric steam cookers.

$$\Delta\text{Water (gallons)} = (W_{BASE} - W_{ENERGYSTAR®}) * HOURS_{Day} * Days$$

Where

W_{BASE} = Water Consumption Rate of Base Steamer (gal/hr)

= 40[237]

$W_{ENERGYSTAR}$ = Water Consumption Rate of ENERGY STAR® Steamer look up[238]

=Actual, or

Equipment Type	gal/hr
Boilerless	1.69
Steam Generation	6.6

For example, a boilerless electric 3 pan steamer with in a full service restaurant

$\Delta\text{Water (gallons)} = (40 - 1.69) * 7 * 365.25$

$= 97{,}949\ gallons$

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = $[Gas\ Cooking\ Consumption\ Replaced]$

$=[(Idle\ Energy_{GasBase} + Preheat\ Energy_{GasBase} + Cooking\ Energy_{GasBase}) * 1/100{,}000 * Days]$

ΔkWh = $[Electric\ Cooking\ Consumption\ Added]$

$=-[(Idle\ Energy_{ElecEE} + Preheat\ Energy_{ElecEE} + Cooking\ Energy_{ElecEE}) * Days]$

[237] FSTC (2002). Commercial Cooking Appliance Technology Assessment. Chapter 8: Steamers.

[238] Average water consumption by equipment type calculated from the ENERGY STAR Qualified Products List, Accessed 06/02/2023.

REVIEW DEADLINE: 1/1/2028

4.2.4 Conveyor Oven

DESCRIPTION

This measure applies to natural gas fired high efficiency conveyor ovens installed in commercial kitchens replacing existing natural gas units with conveyor width greater than 25 inches.

Conveyor ovens are available using four different heating processes: infrared, natural convection with a ceramic baking hearth, forced convection or air impingement, or a combination of infrared and forced convection. Conveyor ovens are typically used for producing a limited number of products with similar cooking requirements at high production rates. They are highly flexible and can be used to bake or roast a wide variety of products including pizza, casseroles, meats, breads, and pastries.

Some manufacturers offer an air-curtain feature at either end of the cooking chamber that helps to keep the heated air inside the conveyor oven. The air curtain operates as a virtual oven wall and helps reduce both the idle energy of the oven and the resultant heat gain to the kitchen.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a natural gas conveyor oven with a tested baking energy efficiency > 42% and an idle energy consumption rate < 57,000 Btu/hr utilizing ASTM standard F1817.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an existing pizza deck oven at end of life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years.[239]

DEEMED MEASURE COST

The incremental capital cost for this measure is $2230.[240]

[240] Ibid.

FOSSIL FUEL SAVINGS[241]

$$\Delta\text{Therms} = ((\Delta DailyPreheatEnergy + \Delta DailyIdleEnergy + \Delta DailyCookingEnergy) * Days) / 100{,}000$$

Where:

ΔTherms = Annual therms calculated as in the equation above

Days = Annual days of kitchen operation

=Actual, if unknown assume 365.25

$$\Delta\text{DailyPreheatEnergy} = (PreheatEnergy_{Base} * Preheats) - (PreheatEnergy_{EE} * Preheats)$$

Where:

ΔDailyPreheatEnergy = Energy savings per day when gas conveyor oven is preheating calculated as in the equation above

$PreheatEnergy_{Base}$ = Preheat energy of baseline gas conveyor oven

= Actual, if unknown use 35,000 Btu

$PreheatEnergy_{EE}$ = Preheat energy of efficient conveyor oven

= Actual, if unknown use 18,000 Btu

Preheats = Number of preheats per day

= Actual, if unknown use 1

$$\Delta\text{DailyIdleEnergy} = (IdleRateGas_{Base} * (Hours - FoodCooked / ProductionGas_{Base} - (Preheats * PreheatTime / 60)) - (IdleRateGas_{EE} * (Hours - FoodCooked / ProductionGas_{EE} - (Preheats * PreheatTime / 60))$$

Where:

ΔDailyIdleEnergy = Energy savings per day when gas conveyor oven is idle as calculated in the equation above

Hours = Average daily hours of operation

=Actual, if unknown assume 12 hours

$IdleRateGas_{Base}$ = Idle energy rate of baseline gas conveyor oven

=Actual, if unknown use 70,000 Btu/hr

$IdleRateGas_{EE}$ = Idle energy rate of efficient gas conveyor oven

=Actual, if unknown use 57,000 Btu/hr

FoodCooked = Food cooked per day

= Actual, if unknown use 250 pizzas

Preheats = Number of preheats per day

= Actual, if unknown use 1

[241] All inputs are taken from PG&E Workpaper PGECOFST117 Commercial Conveyor Oven – Gas Revision #6, published April 1, 2016, unless otherwise referenced.

PreheatTime = Length of one preheat

= Actual, if unknown use 15 minutes

$ProductionGas_{Base}$ = Production capacity of baseline gas conveyor oven

= 150 pizzas per hour

$ProductionGas_{EE}$ = Production capacity of efficient gas conveyor oven

= Actual, if unknown use 220 pizzas per hour

ΔDailyCookingEnergy =$(FoodCooked * EFOOD_{Gas}/EFF_{Base}) - (FoodCooked * EFOOD_{Gas}/EFF_{EE})$

Where:

ΔDailyCookingEnergy = Energy savings per day when gas conveyor oven is cooking

FoodCooked = Food cooked per day

= Actual, if unknown use 250 pizzas

$EFOOD_{Gas}$ = ASTM energy to food for gas conveyor oven

= 190 Btu/pizza

EFF_{Base} = Cooking efficiency of baseline conveyor oven

= Actual, if unknown use 20%

EFF_{EE} = Cooking efficiency of efficient conveyor oven

= Actual, if unknown use 42%

For example, an efficient conveyor oven compared to baseline conveyor oven using default values from above would save.

ΔTherms = $((\Delta DailyPreheatEnergy + \Delta DailyIdleEnergy + \Delta DailyCookingEnergy) * Days) / 100{,}000$

Where:

ΔDailyPreheatEnergy =$(35{,}000 * 1) - (18{,}000 * 1)$

= $17{,}000\ btu$

ΔDailyIdleEnergy =$(70{,}000 * (12 - 250 / 150 - (1 * 15/60)) - (57{,}000 * 12 - 250 / 220 - (1 * 15/60))$

= $21{,}835\ btu$

ΔDailyCookingEnergy = $(250 * 190/0.2) - (250 * 190/0.42)$

= 124,405 btuΔTherms = $(17{,}000 + 21{,}835 + 124{,}405) * 365.25/100000$

= $596\ therms$

REVIEW DEADLINE: 1/1/2028

4.2.5 ENERGY STAR Convection Oven

DESCRIPTION

This measure applies to electric or natural gas fired ENERGY STAR[242] convection ovens installed in a commercial kitchen.

Commercial convection ovens that are ENERGY STAR certified have higher heavy load cooking efficiencies, and lower idle energy rates, making them up to 20 percent more efficient than standard models. Energy savings estimates are for ovens using full size (18" x 36") sheet pans.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must meet ENERGY STAR requirements listed in ENERGY STAR Commercial Ovens Specifications Version 3.0.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a convection oven that is not ENERGY STAR certified and is at end of life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years.[243]

DEEMED MEASURE COST

The incremental capital cost for this measure uses actual costs, otherwise use costs outlined below:[244]

Equipment Type	Baseline Equipment Cost	Efficient Equipment Cost	Incremental Cost
Electric	$7,652	$8,612	$960
Gas	$7,510	$9,884	$2,374

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

Summer Peak Coincidence Factor for measure is assumed to be 0.90.[245]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS

Non-Fuel Switch Measures

[242] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[243] Lifetime from ENERGY STAR Commercial Kitchen Equipment Savings Calculator, Oven Calculations, which cites reference as "FSTC research on available models, 2009".
[244] Costs sourced from California SWFS001_Convection_Oven_IMC_Analysis_-_2022-07-25
[245] Itron, Inc. 2005. 2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report. Prepared for Southern California Edison.Type equation here.

The algorithm below applies to ENERGY STAR compared to baseline electric convection ovens:

$$\Delta kWh = (\Delta DailyIdle\ Energy + \Delta DailyPreheat\ Energy + \Delta DailyCooking\ Energy) * Days$$

The algorithm below applies to ENERGY STAR compared to baseline gas convection ovens:

$$\Delta Therms = (\Delta DailyIdle\ Energy + \Delta DailyPreheat\ Energy + \Delta DailyCooking\ Energy) * Days / 100{,}000$$

Fuel Switch/Electrification Measures

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

$$SiteEnergySavings\ (MMBTUs) = [GasConsumptionReplaced] - [ElectricConsumptionAdded]$$

$$= [(DailyIdle\ Energy_{\ GasBase} + DailyPreheat\ Energy_{GasBase} + DailyCooking\ Energy_{GasBase}) * 1/1{,}000{,}000 * Days] -$$

$$[(DailyIdle\ Energy_{ElecEE} + DailyPreheat\ Energy_{ElecEE} + DailyCooking\ Energy)_{ElecEE} * 3412/1{,}000{,}000 * Days]$$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

$$\Delta DailyIdleEnergy = (IdleBase * IdleBaseTime) - (IdleENERGYSTAR * IdleENERGYSTARTime)$$

$$\Delta DailyCookingEnergy = (LB * EFOOD / Eff_{Base}) - (LB * EFOOD / Eff_{ENERGYSTAR})$$

$$\Delta DailyPreheatEnergy = (PreheatNumber * PreheatTimeBase/60 * PreheatRateBase) - (PreheatNumber * PreheatTimeENERGYSTAR/60 * PreheatRateENERGYSTAR)$$

$$DailyIdle\ Energy_{GasBase} = (IdleBase_{Gas} * IdleBaseTime_{Gas})$$

$$DailyCooking\ Energy_{GasBase} = (LB * EFOOD / Eff_{BaseGas})$$

$$DailyIdle\ Energy_{ElecEE} = (IdleENERGYSTAR_{Elec} * IdleENERGYSTARTime)$$

$$DailyCooking\ Energy_{ElecEE} = (LB * EFOOD / Eff_{ENERGYSTARElec})$$

Where[246]:

IdleENERGYSTAR = Idle energy rate

= Actual, if unknown assume:

Oven Type	IdleENERGYSTAR
Electric Half Size	0.8 kW/h
Electric Full-Size ≥ 5 pans	1.2 kW/h
Electric Full-Size < 5 pans	1.0 kW/h
Natural Gas	8,027 Btu/h

IdleBase = Idle energy rate

Oven Type	IdleBASE
Electric Half Size	1.51 kW/h
Electric Full-Size ≥ 5 pans	1.63 kW/h
Electric Full-Size < 5 pans	1.29 kW/h
Natural Gas	12,239 Btu/h

IdleENERGYSTARTime = $ENERGY\ STAR\ Idle\ Time\ (hours)$

$=HOURsday - LB/PC_{ENERGYSTAR} - PreHeatTime_{ENERGYSTAR}/60$

Using defaults:

Oven Type	Calculation	IdleENERGYSTARTime
Electric Half Size	= 12 – 61/42 – 8/60	10.4
Electric Full-Size ≥ 5 pans	= 12 – 122/98 – 9/60	10.6
Electric Full-Size < 5 pans	= 12 – 122/65 – 9/60	10.0
Natural Gas	= 12 – 100/90 – 11/60	10.7

HOURSday = Average Daily Operation

= custom or if unknown, use 12 hours

LB = Food cooked per day

= custom or if unknown, use 100 pounds for gas oven, 61 lbs for half sized electric oven or 122 lbs for full-sized electric oven[247]. For fuel switching scenarios, use same LB assumption for both baseline and efficient.

$PC_{ENERGYSTAR}$ = Production Capacity ENERGY STAR (lb/hr)

= Actual, if unknown use:

Oven Type	$PC_{ENERGYSTAR}$
Electric Half Size	42
Electric Full-Size ≥ 5 pans	98
Electric Full-Size < 5 pans	65
Natural Gas	90

$PreheatTime_{ENERGYSTAR}$ = preheat length of ENERGY STAR oven

= custom or if unknown use[248]:

[246] All assumptions except where noted are based upon data package provided alongside ENERGY STAR Commercial Ovens Specifications Version 3.0. See ENERGY STAR v3 Commercial Ovens Data Package.xlsx.
[247] Gas default is based upon the ENERGY STAR Commercial Kitchen Calculator. Electric defaults based on data from the Regional Technical Forum for the Northwest Council (Commercial Cooking Convection Oven Calculator, UES Measure Workbook), see "ComCookingConvectionOven_v4_0.xlsm".

Electric Full-Size < 5 pans	1.39
Natural Gas	44,000

PreheatNumber =Number of preheats per day

= Actual; or if unknown use 1

For example, an ENERGY STAR gas oven compared to baseline gas oven using default values from above would save.

ΔTherms = $(\Delta Idle\ Energy\ +\ \Delta Preheat\ Energy\ +\ \Delta Cooking\ Energy) * Days\ /100000$

Where:

ΔDailyIdleEnergy $=(12{,}239 * 10.7) - (8{,}027 * 10.7)$
$= 45{,}068\ btu$

ΔDailyPreheatEnergy $= (1 * 12/60 * 76{,}000) - (1 * 12/60 * 44{,}000)$
$= 6{,}400\ btu$

ΔDailyCookingEnergy $= (100 * 250/0.47) - (100 * 250/0.52)$
$= 5{,}115\ btu$

ΔTherms $= (45068 + 6{,}400 + 5115) * 365.25\ /100000$
$= 207\ therms$

An ENERGY STAR half sized electric oven compared to baseline electric oven using default values from above would save.

ΔkWh = $(\Delta Idle\ Energy\ +\ \Delta DailyPreheat\ Energy\ +\ \Delta Cooking\ Energy) * Days\ /100000$

Where:

ΔDailyIdleEnergy $=(1.51 * 10.5) - (0.8 * 10.4)$
$= 7.5\ kWh$

ΔDailyPreheatEnergy $= (1 * 9/60 * 0.89) - (1 * 9/60 * 0.70)$
$= 0.03\ kWh$

ΔDailyCookingEnergy $= (61 * 0.0732/0.64) - (61 * 0.0732/0.75)$
$= 1.02\ kWh$

ΔkWh $= (7.5 + 0.03 + 1.02) * 365.25$
$= 3{,}123\ kWh$

An ENERGY STAR full sized electric oven ≥ 5 pans compared to baseline electric oven using default values from above would save.

ΔkWh=$(\Delta Idle\ Energy\ +\ \Delta DailyPreheat\ Energy\ +\ \Delta Cooking\ Energy) * Days\ /100000$

Where:

ΔDailyIdleEnergy $=(1.63 * 10.7) - (1.2 * 10.6)$
$= 4.7\ kWh$

ΔDailyPreheatEnergy $= (1 * 9/60 * 1.56) - (1 * 9/60 * 1.39)$
$= 0.03\ kWh$

ΔDailyCookingEnergy $= (122 * 0.0732/0.74) - (122 * 0.0732/0.80)$
$= 0.9\ kWh$

ΔkWh $= (4.7 + 0.03 + 0.9) * 365.25$
$= 2056\ kWh$

An ENERGY STAR full sized electric oven < 5 pans compared to baseline electric oven using default values from above would save.

$$\Delta kWh = (\Delta Idle\ Energy\ +\ \Delta Cooking\ Energy) * Days\ /100000$$

Where:

ΔDailyIdleEnergy $=(1.29 * 10.2) - (1.0 * 10.0)$
$= 3.2\ kWh$

ΔDailyPreheatEnergy $= (1 * 9/60 * 1.56) - (1 * 9/60 * 1.39)$
$= 0.03\ kWh$

ΔDailyCookingEnergy $= (122 * 0.0732/0.765) - (122 * 0.0732/0.81)$
$= 0.65\ kWh$

ΔkWh $= (3.2 + 0.03 + 0.65) * 365.25$
$= 1{,}417\ kWh$

An ENERGY STAR full sized >5 pan electric oven compared to baseline gas oven assuming 100 lbs food cooked per day and using other default values from above would save.

SiteEnergySavings (MMBTUs) $= [GasConsumptionReplaced] - [ElectricConsumptionAdded]$

$$=[(DailyIdle\ Energy_{GasBase} + DailyPreheat\ Energy_{GasBase} + DailyCooking\ Energy_{GasBase}) * 1/1{,}000{,}000 * Days] - [(DailyIdle\ Energy_{ElecEE} + DailyPreheat\ Energy_{ElecEE}\ DailyCooking\ Energy_{ElecEE}) * 3412/1{,}000{,}000 * Days]$$

$DailyIdleEnergy_{GasBase}$ $=(12{,}239 * 10.7)$
$= 130957\ btu$

$DailyPreheatEnergy_{GasBase}$ $= (1 * 12/60 * 76{,}000)$
$= 15200\ btu$

$DailyCookingEnergy_{GasBase}$ $= (100 * 250/0.47)$
$= 53191\ btu$

$DailyIdleEnergy_{ElecEE}$ $= (1.2 * 10.6)$
$= 12.7\ kWh$

$DailyPreheatEnergy_{ElecEE}$ $= (1 * 9/60 * 1.39)$
$= 0.21\ kWh$

$DailyCookingEnergy_{ElecEE}$ $= (100 * 0.0732/0.80)$
$= 9.2\ kWh$

SiteEnergySavings (MMBTUs) $=((130957 + 15200 + 53191) * 1/1{,}000{,}000 * 365.25) - ((12.7 + 0.21 + 9.2) * 3412/1{,}000{,}000 * 365.25)$
$= 45.3\ MMBtu$

If supported by an electric utility: ΔkWh = ΔSiteEnergySavings * 1,000,000 / 3,412

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Non-fuel switch measures:

$$\Delta kW = ((\Delta DailyIdle\ Energy + \Delta DailyPreheat\ Energy + \Delta DailyCooking\ Energy) / HOURSDay * CF$$

Fuel switch measures:

$$\Delta kW = -((DailyIdle\ Energy_{ElecEE} + DailyPreheat\ Energy_{ElecEE} + DailyCooking\ Energy_{ElecEE}) / HOURSDay * CF$$

Where:

CF =Summer Peak Coincidence Factor

= 0.90[251]

Other values as defined above.

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms $= [Gas\ Cooking\ Consumption\ Replaced]$

$= [(DailyIdle\ Energy_{GasBase} + DailyPreheat\ Energy_{GasBase} + DailyCooking\ Energy_{GasBase}) * 1/100{,}000 * Days]$

ΔkWh $= [Electric\ Cooking\ Consumption\ Added]$

$= -[(DailyIdle\ Energy_{ElecEE} + DailyPreheat\ Energy_{ElecEE} + DailyCooking\ Energy_{ElecEE}) * Days]$

REVIEW DEADLINE: 1/1/2029

4.2.6 ENERGY STAR Dishwasher

DESCRIPTION

This measure applies to ENERGY STAR[252] high and low temp under counter, stationary single tank door type, single tank conveyor, and multiple tank conveyor dishwashers, as well as high temp pot, pan, and utensil dishwashers installed in a commercial kitchen.

This measure was developed to be applicable to the foll

owing program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be an ENERGY STAR certified dishwasher meeting idle energy rate (kW), washing energy and water consumption (gallons/rack) limits, as determined by both machine type and sanitation approach (chemical/low temp versus high temp).

ENERGY STAR Requirements (Version 3.0, effective July 27, 2021)

Dishwasher Type	High Temp Efficiency Requirements			Low Temp Efficiency Requirements		
	Idle Energy Rate	Washing Energy	Water Consumption	Idle Energy Rate	Washing Energy	Water Consumption
Under Counter	≤ 0.30 kW	≤ 0.35 kWh/rack	≤ 0.86 GPR	≤ 0.25 kW	≤ 0.15 kWh/rack	≤ 1.19 GPR
Stationary Single Tank Door	≤ 0.55 kW	≤ 0.35 kWh/rack	≤ 0.89 GPR	≤ 0.30 kW	≤ 0.15 kWh/rack	≤ 1.18 GPR
Pot, Pan, and Utensil	≤ 0.90 kW	≤ 0.55 + 0.05 * SF_{rack}	≤ 0.58 GPSF	N/A		
Single Tank Conveyor	≤ 1.20 kW	≤ 0.36 kWh/rack	≤ 0.70 GPR	≤ 0.85 kW	≤ 0.16 kWh/rack	≤ 0.79 GPR
Multiple Tank Conveyor	≤ 1.85 kW	≤ 0.36 kWh/rack	≤ 0.54 GPR	≤ 1.00 kW	≤ 0.22 kWh/rack	≤ 0.54 GPR

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a new dishwasher that is not ENERGY STAR certified.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be:[253]

Dishwasher Type		Equipment Life
Low Temp	Under Counter	10
	Stationary Single Tank Door	10
	Single Tank Conveyor	10
	Multi Tank Conveyor	10
High Temp	Under Counter	10
	Stationary Single Tank Door	10
	Single Tank Conveyor	10
	Multi Tank Conveyor	10
	Pot, Pan, and Utensil	10

DEEMED MEASURE COST

The incremental capital cost for this measure is provided below:[254]

[252] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[253] Lifetime from ENERGY STAR Commerical Food Service Equipment Calculator, updated March 2024 which cites reference as "EPA/FSTC research on available models, 2013"

[254] Measure cost from ENERGY STAR Commercial Kitchen Equipment Savings Calculator, updated March 2024 which cites reference as "Difference between a similar ENERGY STAR and non-qualifying model EPA research using AutoQuotes, 2016 (for high/low temp undercounter/single door) and 2012 (all other types)".

Dishwasher Type		Incremental Cost
Low Temp	Under Counter	$234
	Stationary Single Tank Door	$1,469
	Single Tank Conveyor	$0
	Multi Tank Conveyor	$970
High Temp	Under Counter	$156
	Stationary Single Tank Door	$3,309
	Single Tank Conveyor	$2,050
	Multi Tank Conveyor	$970
	Pot, Pan, and Utensil	$1,710

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

Summer Peak Coincidence Factor for measure is provided below for different restaurant types:[255]

Location	CF
Fast Food Limited Menu	0.32
Fast Food Expanded Menu	0.41
Pizza	0.46
Full Service Limited Menu	0.51
Full Service Expanded Menu	0.36
Cafeteria	0.39

Algorithm

CALCULATION OF SAVINGS

ENERGY STAR dishwashers save energy in three categories: building water heating, booster water heating and idle energy. Building water heating and booster water heating could be either electric or natural gas.

ELECTRIC ENERGY SAVINGS

Non-Fuel Switch measures:

Custom calculation below[256], otherwise use deemed values found within the tables that follow.

$$\Delta\text{kWh} = \Delta\text{BuildingEnergy} + \Delta\text{BoosterEnergy} + \Delta\text{IdleEnergy}$$

Where:

ΔBuildingEnergy = Change in annual electric energy consumption of building water heater

$$= [(WaterUseBase * RacksWashed * Days) * (\Delta Tin * 1.0 * 8.2 \div EffHeater \div 3{,}412)] - [(WaterUseESTAR * RacksWashed * Days) * (\Delta Tin * 1.0 * 8.2 \div EffHeater \div 3{,}412)]$$

[255] Values taken from Minnesota Technical Reference Manual (Version 2.2, effective May 2, 2018), 'Electric Oven and Range' measure and are based upon "Project on Restaurant Energy Performance-End-Use Monitoring and Analysis", Appendixes I and II, Claar, et. al., May 1985

[256] Algorithms and assumptions derived from ENERGY STAR Commercial Kitchen Equipment Savings Calculator.

ΔBoosterEnergy = Annual electric energy consumption of booster water heater[257]

$$= [(WaterUseBase * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{3{,}412})] - [(WaterUseESTAR * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{3{,}412}]$$

ΔIdleEnergy = Annual idle electric energy consumption of dishwasher

$$= [IdleDrawBase * \frac{Hours * Days - Days * RacksWashed * WashTime}{60}] - [IdleDrawESTAR * \frac{Hours * Days - Days * RacksWashed * WashTime}{60}]$$

Fuel-Switch / Electrification Measures:

Fuel-switching / electrification is only applicable in the following scenario:

Base Case: High Temp Dishwasher with an Electric Booster Heater and a Gas Building Heater

Measure Case: High Temp Heat Recovery Dishwasher with an Electric Booster Heater and no associated Building Heater energy usage.

Fuel-switch / electrification measures must product positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. The following algorithm can be used to determine eligibility:

SiteEnergySavings (MMBTUs) $= [GasConsumptionReplaced + kWhCosumptionReplaced] - [ElectricalConsumptionAdded]$

$$= \left[\frac{AnnualBuildingEnergyGasBaseTHERMS}{10} + (\frac{AnnualBoosterEnergyElectricBase + AnnualIdleEnergyElectricBase + WaterEnergyGasBase) * 3{,}412}{1{,}000{,}000}\right] - \left[\frac{(AnnualBoosterEnergyElectricMeasure + AnnualIdelEnergyElectricMeasure + WaterEnergyElectricMeasure) * 3{,}412}{1{,}000{,}000}\right]$$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claims are dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A

[257] Booster water heater energy only applies to high-temperature dishwashers.

Where:

$WaterUse_{Base}$	= Water use per rack (gal) of baseline dishwasher
	= Custom or if unknown, use value from table below as determined by machine type and sanitation method
$WaterUse_{ESTAR}$	= Water use per rack (gal) of ENERGY STAR dishwasher
	= Custom or if unknown, use value from table below as determined by machine type and sanitation method
RacksWashed	= Number of racks washed per day
	= Custom or if unknown, use value from table below as determined by machine type and sanitation method
Days	= Annual days of dishwasher operation
	= Custom or if unknown, use 365.25 days per year
ΔT_{in}	= Inlet water temperature increase (°F)
	= Custom or if unknown, use 70 °F for building water heaters and 40 °F for booster water heaters
	Note for Heat Recovery Dish Washers which accept cold water the temperature increase is 0 °F for building water heaters and 110 °F for booster water heaters.
1.0	= Specific heat of water (Btu/lb/°F)
8.2	= Density of water (lb/gal)
Eff_{Heater}	= Efficiency of water heater
	= Custom or if unknown, use 98% for electric building and booster water heaters
3,412	= kWh to Btu conversion factor
$IdleDraw_{Base}$	= Idle power draw (kW) of baseline dishwasher
	= Custom or if unknown, use value from table below as determined by machine type and sanitation method
$IdleDraw_{ESTAR}$	= Idle power draw (kW) of ENERGY STAR dishwasher
	= Custom or if unknown, use value from table below as determined by machine type and sanitation method
Hours	= Average daily hours of dishwasher operation
	= Custom or if unknown, use 18 hours per day
WashTime	= Typical wash time (min)
	= Custom or if unknown, use value from table below as determined by machine type and sanitation method
60	= Minutes to hours conversion factor

For example, an ENERGY STAR high-temperature, under counter dishwasher with electric building and electric booster water heating with defaults from the calculation above and the table below would save:

ΔkWh = ΔBuildingEnergy + ΔBoosterEnergy + ΔIdleEnergy

Where:

ΔBuildingEnergy = [(1.09 * 75 * 365.25) * (70 *1.0 * 8.2 ÷ 0.98 ÷ 3,412)] - [(0.86 * 75 * 365.25) * (70 *1.0 * 8.2 ÷ 0.98 ÷ 3,412)]

= 1,082 kWh

ΔBoosterEnergy = [(1.09 * 75 * 365.25) * (40 *1.0 * 8.2 ÷ 0.98 ÷ 3,412)] - [(0.86 * 75 * 365.25) * (40 *1.0 * 8.2 ÷ 0.98 ÷ 3,412)]

= 618 kWh

ΔIdleEnergy = [0.36 * (18 *365.25 – 365.25 * 75 * 2.5 ÷ 60)] –

[0.30 * (18 *365.25 – 365.25 * 75 * 2.5 ÷ 60)]

= 326 kWh

ΔkWh = 1,082 + 618 + 340

= 2,026 kWh

Default values for WaterUse, RacksWashed, kW_{Idle}, and WashTime are presented in the table below.

Low Temperature	RacksWashed	WashTime	WaterUse		IdleDraw	
	All Dishwashers	All Dishwashers	Conventional	ENERGY STAR	Conventional	ENERGY STAR
Under Counter	75	2.5	1.73	1.19	0.41	0.25
Stationary Single Tank Door	280	7.0	2.10	1.18	0.32	0.30
Single Tank Conveyor	400	2.0	1.31	0.79	0.75	0.85
Multi Tank Conveyor	600	3.0	1.04	0.54	1.74	1.00
High Temperature	**All Dishwashers**	**All Dishwashers**	**Conventional**	**ENERGY STAR**	**Conventional**	**ENERGY STAR**
Under Counter	75	2.5	1.09	0.86	0.36	0.30
Stationary Single Tank Door	280	7.0	1.29	0.89	0.51	0.55
Single Tank Conveyor	400	2.0	0.87	0.70	1.30	1.20
Multi Tank Conveyor	600	2.0	0.97	0.54	1.84	1.85
Pot, Pan, and Utensil	200	10.0	0.70	0.58	1.10	0.90

Savings for all water heating combinations are presented in the tables below (calculated without rounding variables as provided above).

Electric building and electric booster water heating

Dishwasher Type		kWh_{Base}	kWh_{ESTAR}	ΔkWh
Low Temp	Under Counter	17,299	11,117	6,182
	Stationary Single Tank Door	54,507	37,252	17,255
	Single Tank Conveyor	63,517	48,138	15,378
	Multi Tank Conveyor	96,834	73,971	22,863
High Temp	Under Counter	19,114	17,634	1,480
	Stationary Single Tank Door	74,430	62,533	11,897
	Single Tank Conveyor	97,362	87,158	10,204
	Multi Tank Conveyor	166,643	121,569	45,074
	Pot, Pan, and Utensil	86,494	75,516	10,979

Electric building and natural gas booster water heating

Dishwasher Type		kWh_{Base}	kWh_{ESTAR}	ΔkWh
Low Temp	Under Counter	17,299	11,117	6,182
	Stationary Single Tank Door	54,507	37,252	17,255
	Single Tank Conveyor	63,517	48,138	15,378
	Multi Tank Conveyor	96,834	73,971	22,863
High Temp	Under Counter	16,185	15,323	862
	Stationary Single Tank Door	61,488	53,604	7,884
	Single Tank Conveyor	84,893	77,125	7,768
	Multi Tank Conveyor	145,789	109,960	35,829
	Pot, Pan, and Utensil	81,478	71,359	10,119

Natural gas building and electric booster water heating

Dishwasher Type		kWh_{Base}	kWh_{ESTAR}	ΔkWh
Low Temp	Under Counter	2,320	1,414	905
	Stationary Single Tank Door	1,285	1,205	80
	Single Tank Conveyor	4,380	4,964	-584
	Multi Tank Conveyor	9,527	5,475	4,052
High Temp	Under Counter	4,955	4,008	946
	Stationary Single Tank Door	14,990	11,137	3,852
	Single Tank Conveyor	20,061	17,041	3,020
	Multi Tank Conveyor	31,599	22,413	9,186
	Pot, Pan, and Utensil	8,228	6,784	1,444

Natural gas building and natural gas booster water heating

Dishwasher Type		kWh_{Base}	kWh_{ESTAR}	ΔkWh
Low Temp	Under Counter	2,320	1,414	905
	Stationary Single Tank Door	1,285	1,205	80
	Single Tank Conveyor	4,380	4,964	-584
	Multi Tank Conveyor	9,527	5,475	4,052
High Temp	Under Counter	2,025	1,697	328
	Stationary Single Tank Door	2,048	2,208	-161
	Single Tank Conveyor	7,592	7,008	584
	Multi Tank Conveyor	10,746	10,804	-58
	Pot, Pan, and Utensil	3,212	2,628	584

For example, the fuel switch measure of a High Temp Heat Recovery Dishwasher with an Electric Booster Heater and no associated Building Heater energy usage, in place of a High Temp Dishwasher with an Electric Booster Heater and a Gas Building Heater.

SiteEnergySavings (MMBTUs)	= [GasConsumptionReplaced + kWhCosumptionReplaced] – [ElectricalConsumptionAdded] = [$AnnualBuildingEnergy_{GasBaseTHERMS}$ / 10 + ($AnnualBoosterEnergy_{ElectricBase}$ + $AnnualIdleEnergy_{ElectricBase}$ + $WaterEnergy_{GasBase}$) *3,412 / 1,000,000] – [($AnnualBoosterEnergy_{ElectricMeasure}$ + $AnnualIdleEnergy_{ElectricMeasure}$ + $WaterEnergy_{ElectricMeasure}$) * 3,412 / 1,000,000]
$AnnualBuildingEnergy_{GasBaseTHERMS}$	= ($WaterUse_{Base}$ * RacksWashed * Days)*(ΔT_{in} * 1.0 * 8.2 / Eff_{Heater} / 100,000) = (1.09 * 75 * 365.25) * (70 * 1 * 8.2 / 0.8 / 100,000) = 214 Therm
$AnnualBoosterEnergy_{ElectricBase}$	= ($WaterUse_{Base}$ * RacksWashed * Days) * (ΔT_{in} *1.0 * 8.2 / Eff_{Heater} / 3,412) = (1.09 * 75 * 365.25) * (40 * 1 * 8.2 / 0.98 / 3,412) = 2,929 kWh
$AnnualIdleEnergy_{ElectricBase}$	= $IdleDraw_{Base}$* (Hours * Days – Days * RacksWashed * WashTime / 60) = 0.36 * (18 * 365.25 – 365.25 * 75 * 2.5 / 60) = 1,956 kWh
$WaterEnergy_{ElectricBase}$	= ($WaterUse_{Base}$ * RacksWashed * Days) / 1,000,000 * 5,010 = (0.86 * 75 * 365.25) / 1,000,000 * 5,010 = 150 kWh
$AnnualBoosterEnergy_{ElectricMeasure}$	= ($WaterUse_{Measure}$ * RacksWashed * Days) * (ΔT_{in} *1.0 * 8.2 / Eff_{Heater} / 3,412) = (0.86 * 75 * 365.25) * (110 * 1 * 8.2 / 0.98 / 3,412) = 6,355 kWh
$AnnualIdleEnergy_{ElectricMeasure}$	= $IdleDraw_{Measure}$* (Hours * Days – Days * RacksWashed * WashTime / 60) = 0.3 * (18 * 365.25 – 365.25 * 75 * 2.5 / 60) = 1,630 kWh
$WaterEnergy_{ElectricMeasure}$	= ($WaterUse_{Measure}$ * RacksWashed * Days) / 1,000,000 * 5,010 = (0.86 * 75 * 365.25) / 1,000,000 * 5,010 = 118 kWh
SiteEnergySavings (MMBTUs)	= [214 / 10 + (2,929 + 1,956 + 150) * 3,412 / 1,000,000] – [(6,355 + 1,630 + 118) * 3,412 / 1,000,000] = 10.9 MMBTU
If supported by an electric utility	= SiteEnergySavings * 1,000,000 / 3,412 = 10.9 * 1,000,000 / 3,412 = 3,195 kWh

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \frac{\Delta Water\ (gallons)}{1{,}000{,}000} * Ewater\ total$$

Where

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

= 5,010[258]

For example, an ENERGY STAR low-temperature, under-counter dishwasher with defaults from the calculation above and the table within the electric energy savings characterization would save:

ΔWater = ($WaterUse_{Base}$ * RacksWashed * Days) - ($WaterUse_{ESTAR}$ * RacksWashed * Days)

ΔWater (gallons) = (1.73 * 75 * 365.25) - (1.19 * 75 * 365.25)

= 14,793 gallons

ΔkWh_{water} = 14,793/1,000,000*5,010

= 74 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh}{AnnualHours} * CF$$

Where:

ΔkWh = Annual kWh savings from measure as calculated above. Note: do not include the secondary savings in this calculation.

AnnualHours $= Hours * Days$

= Custom, or if unknown assume (18 * 365.25 =) 6575 annual hours

CF = Summer Peak Coincidence Factor

= dependent on restaurant type:[259]

Location	CF
Fast Food Limited Menu	0.32
Fast Food Expanded Menu	0.41
Pizza	0.46
Full Service Limited Menu	0.51
Full Service Expanded Menu	0.36
Cafeteria	0.39

[258] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

[259] Values taken from Minnesota Technical Reference Manual (Version 2.2, effective May 2, 2018), 'Electric Oven and Range' measure and are based upon "Project on Restaurant Energy Performance-End-Use Monitoring and Analysis", Appendixes I and II, Claar, et. al., May 1985.

For example, a low temperature undercounter dishwasher in a Full Service Limited Menu restaurant with electric building and booster water heaters would save:

ΔkW = ΔkWh/ AnnualHours * CF

= 3645/6575*0.51

= 0.283 kW

FOSSIL FUEL SAVINGS

$$\Delta\text{Therms} = \Delta\text{BuildingEnergy} + \Delta\text{BoosterEnergy}$$

Where:

ΔBuildingEnergy = Change in annual natural gas consumption of building water heater

$$= [(WaterUseBase * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{100{,}000})]$$

$$- [(WaterUseESTAR * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{100{,}000})]$$

ΔBoosterEnergy = Change in annual natural gas consumption of booster water heater

$$= [(WaterUseBase * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{100{,}000})]$$

$$- [(WaterUseESTAR * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{100{,}000})]$$

Where:

$WaterUse_{Base}$ = Water use per rack (gal) of baseline dishwasher

= Custom or if unknown, use value from table within the electric energy savings characterization as determined by machine type and sanitation method

$WaterUse_{ESTAR}$ = Water use per rack (gal) of ENERGY STAR dishwasher

= Custom or if unknown, use value from table within the electric energy savings characterization as determined by machine type and sanitation method

RacksWashed = Number of racks washed per day

= Custom or if unknown, use value from table within the electric energy savings characterization as determined by machine type and sanitation method

Days = Annual days of dishwasher operation

= Custom or if unknown, use 365.25 days per year

ΔT_{in} = Inlet water temperature increase (°F)

= Custom or if unknown, use 70 °F for building water heaters and 40 °F for booster water heaters

1.0 = Specific heat of water (Btu/lb/°F)

8.2 = Density of water (lb/gal)

Eff_{Heater} = Efficiency of water heater

= Custom or 80% for gas building and booster water heaters

100,000 = Therms to Btu conversion factor

For example, an ENERGY STAR high-temperature, under counter dishwasher with gas building and gas booster water heating with defaults from the calculation above and the table within the electric energy savings characterization would save:

ΔTherms = ΔBuildingEnergy + ΔBoosterEnergy

Where:

ΔBuildingEnergy = [(1.09 * 75 * 365.25)*(70 * 1.0 * 8.2 / 0.80 / 100,000)] - [(0.86 * 75 * 365.25)*(70 * 1.0 * 8.2 / 0.80 / 100,000)]

= 45 therms

ΔBoosterEnergy = [(1.09 * 75 * 365.25)*(40 * 1.0 * 8.2 / 0.80 / 100,000)] - [(0.86 * 75 * 365.25) * (40 * 1.0 * 8.2 / 0.80 / 100,000)]

= 26 therms

ΔTherms = 45 + 26

= 71 therms

Savings for all water heating combinations are presented in the tables below.

Electric building and natural gas booster water heating

Dishwasher Type		$Therms_{Base}$	$Therms_{ESTAR}$	ΔTherms
Low Temp	Under Counter	NA	NA	NA
	Stationary Single Tank Door	NA	NA	NA
	Single Tank Conveyor	NA	NA	NA
	Multi Tank Conveyor	NA	NA	NA
High Temp	Under Counter	122	97	26
	Stationary Single Tank Door	541	373	168
	Single Tank Conveyor	521	419	102
	Stationary Single Tank Door	872	485	386
	Pot, Pan, and Utensil	210	174	36

Natural gas building and natural gas booster water heating

	Stationary Single Tank Door	947	653	294
	Single Tank Conveyor	912	734	178
	Multi Tank Conveyor	1,526	849	676
	Pot, Pan, and Utensil	367	304	63

WATER IMPACT DESCRIPTIONS AND CALCULATION

$$\Delta\text{Water} = (\text{WaterUse}_{\text{Base}} * \text{RacksWashed} * \text{Days}) - (\text{WaterUse}_{\text{ESTAR}} * \text{RacksWashed} * \text{Days})$$

Where:

$WaterUse_{Base}$ = Water use per rack (gal) of baseline dishwasher

= Custom or if unknown, use value from table within the electric energy savings characterization as determined by machine type and sanitation method

$WaterUse_{ESTAR}$ = Water use per rack (gal) of ENERGY STAR dishwasher

= Custom or if unknown, use value from table within the electric energy savings characterization as determined by machine type and sanitation method

RacksWashed = Number of racks washed per day

= Custom or if unknown, use value from table within the electric energy savings characterization as determined by machine type and sanitation method

Days = Annual days of dishwasher operation

= Custom or if unknown, use 365.25 days per year

For example, an ENERGY STAR low-temperature, under counter dishwasher with defaults from the calculation above and the table within the electric energy savings characterization would save:

ΔWater = ($WaterUse_{Base}$ * RacksWashed * Days) - ($WaterUse_{ESTAR}$ * RacksWashed * Days)

ΔWater (gallons) = (1.73 * 75 * 365.25) - (1.19 * 75 * 365.25)

= 14,793 gallons

Savings for all dishwasher types are presented in the table below.

	Annual Water Consumption (gallons)		
	Baseline	ENERGY STAR	Savings
Low Temperature			
Under Counter	47,391	32,599	14,793

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = [Gas Consumption Replaced]

$$= [((WaterUseBase * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{100{,}000}))$$

$$+ ((WaterUseBase * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{100{,}000}))]$$

ΔkWh = [Electric Consumption Added]

$$= -[((((WaterUseESTAR * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{3{,}412}))) + (((WaterUseESTAR * RacksWashed * Days) * (\frac{\frac{\Delta Tin * 1.0 * 8.2}{EffHeater}}{3{,}412})))$$

$$+ ((IdleDrawESTAR * (\frac{Hours * Days - Days * RacksWashed * WashTime}{60})))]$$

MEASURE CODE: CI-FSE-ESDW-V09-260101

REVIEW DEADLINE: 1/1/2029

4.2.7 ENERGY STAR Fryer

DESCRIPTION

This measure applies to electric or natural gas fired ENERGY STAR[260] certified fryers installed in a commercial kitchen.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the installed equipment must be an ENERGY STAR certified fryer meeting idle energy rate (W or Btu/hr)) and cooking efficiency (%) limits, as determined by both fuel type and fryer capacity (standard versus large vat).

ENERGY STAR Requirements (Version 3.0, Effective October 1, 2016)

Fryer Capacity	Electric Efficiency Requirements		Natural Gas Efficiency Requirements	
	Idle Energy Rate	Cooking Efficiency Consumption	Idle Energy Rate	Cooking Efficiency Consumption
Standard Open Deep-Fat Fryer	≤ 800 W	≥ 83%	≤ 9,000 Btu/hr	≥ 50%
Large Vat Open Deep-Fat Fryer	≤ 1,100 W	≥ 80%	≤ 12,000 Btu/hr	

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a new electric or natural gas fryer that is not ENERGY STAR certified.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years.[261]

DEEMED MEASURE COST

For the incremental capital costs, please see the table below:[262]

Fuel Source	Size	Incremental Cost
Electric	Standard	$1,500
	Large Vat	$500
Natural Gas	Standard	$1,000
	Large Vat	$2,000

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

Summer Peak Coincidence Factor for measure is assumed to be 0.90.[263]

[260] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[261] Lifetime from ENERGY STAR Commercial Kitchen Equipment Savings Calculator 03-2021,which cites reference as "FSTC research on available models, 2009.

[262] Measure cost from ENERGY STAR Commercial Kitchen Equipment Savings Calculator (last updated March 2021) which cites reference as "Difference between a similar ENERGY STAR and non-qualifying model, EPA research using AutoQuotes, October 2020".

[263] Itron, Inc. 2005. 2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report. Prepared for Southern California Edison.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC AND FOSSIL FUEL ENERGY SAVINGS

Non-Fuel Switch Measures

The algorithm below applies to ENERGY STAR compared to baseline electric fryer:

$$\Delta kWh = (\Delta DailyIdleEnergy + \Delta DailyPreheatEnergy + \Delta DailyCookingEnergy) * Days / 1{,}000$$

The algorithm below applies to ENERGY STAR compared to baseline gas fryer:

$$\Delta Therms = (\Delta DailyIdleEnergy + \Delta DailyPreheatEnergy + \Delta DailyCookingEnergy) * Days / 100{,}000$$

Fuel Switch/Electrification Measures:

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

$$SiteEnergySavings\ (MMBTUs) = [GasConsumptionReplaced] - [ElectricConsumptionAdded]$$

$$= [(DailyIdleEnergy_{GasBase} + DailyPreheatEnergy_{GasBase} + DailyCookingEnergy_{GasBase}) * 1/1{,}000{,}000 * Days] -$$

$$[(DailyIdleEnergy_{ElecEE} + DailyPreheatEnergy_{ElecEE} + DailyCookingEnergy_{ElecEE}) * 3.412/1{,}000{,}000 * Days]$$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

$$\Delta DailyIdleEnergy = (Idle_{Base} * ((HOURS - (PreheatTime/60)) - LB/PC_{Base})) - (Idle_{ESTAR} * ((HOURS - (PreheatTime/60)) - LB/PCESTAR))$$

$$\Delta DailyPreheatEnergy = (PreheatEnergy_{Base} - PreheatEnergy_{ESTAR}) * 1{,}000$$

$$\Delta DailyCookingEnergy = (LB * EFOOD/Eff_{Base}) - (LB * EFOOD/Eff_{ESTAR})$$

$$DailyIdle\ Energy_{GasBase} = (Idle_{BaseGas} * ((HOURS - (PreheatTime/60)) - LB/PC_{BaseGas}))$$

DailyCooking Energy$_{GasBase}$= $(LB * EFOOD / Eff_{BaseGas})$

DailyIdle Energy$_{ElecEE}$ =$(Idle_{ESTARElec} * ((HOURS - (PreheatTime/60)) - LB/PC_{ESTARElec}))$

DailyCooking Energy$_{ElecEE}$ = $(LB * EFOOD / Eff_{ESTAR})$

Where[264]:

Idle$_{Base}$ = Idle energy rate of baseline fryer

Fryer Type	Idle$_{Base}$
Electric Standard	1,200 W/h
Electric Large Vat	1,350 W/h
Natural Gas Standard	14,000 Btu/h
Natural Gas Large Vat	16,000 Btu/h

Idle$_{ESTAR}$ = Idle energy rate of ENERGY STAR electric fryer

= Actual, if unknown use:

Fryer Type	Idle$_{ESTAR}$
Electric Standard	800 W/h
Electric Large Vat	1,100 W/h
Natural Gas Standard	9,000 Btu/h
Natural Gas Large Vat	12,000 Btu/h

HOURS = Average daily hours of operation

= Actual or if unknown, use 16 hours per day for a standard fryer and 12 hours per day for a large vat fryer

PreheatTime = Time required to preheat the fryer

= 15 minutes per day

60 = minutes to hours conversion factor

LB = Food cooked per day

= Actual or if unknown, use 150 pounds

PC$_{Base}$ = Production capacity of baseline fryer (lb/h)

Fryer Type	PC$_{Base}$ (lb/h)
Electric Standard	65
Electric Large Vat	100
Natural Gas Standard	60
Natural Gas Large Vat	100

PC$_{ESTAR}$ = Production capacity of ENERGY STAR fryer

= Actual or if unknown, use

Fryer Type	PC$_{Base}$

[264] Algorithms and assumptions derived from ENERGY STAR Commercial Kitchen Equipment Savings Calculator (last updated March 2021).

	(lb/h)
Electric Standard	70
Electric Large Vat	110
Natural Gas Standard	65
Natural Gas Large Vat	110

$PreheatEnergy_{Base}$ = Total energy used during preheat of baseline fryer

= 2.4 kWh for electric fryers and 18,500Btu for gas fryers

$PreheatEnergy_{ESTAR}$ = Total energy used during preheat of ENERGY STAR fryer

= Actual, or if unknown assume 1.9 kWh for electric fryers and 16,000Btu for gas fryers

EFOOD = ASTM energy to food

= 167 Wh/lb for electric fryers and 570 Btu/lb for gas fryers

Eff_{Base} = Cooking efficiency of baseline electric fryer

Fryer Type	Eff_{Base}
Electric Standard	75%
Electric Large Vat	70%
Natural Gas Standard	35%
Natural Gas Large Vat	35%

Eff_{ESTAR} = Cooking efficiency of ENERGY STAR electric fryer

= Actual or if unknown use:

Fryer Type	Eff_{ESTAR}
Electric Standard	83%
Electric Large Vat	80%
Natural Gas Standard	50%
Natural Gas Large Vat	50%

Days = Annual days of operation

= Custom, or if unknown, use 365.25 days per year

1,000 = Wh to kWh conversion factor

100,000 = Btu to therms conversion factor

For example, an ENERGY STAR standard-sized electric fryer, using default values from the calculation above, would save:

ΔkWh =$(\Delta DailyIdleEnergy + \Delta DailyPreheatEnergy + \Delta DailyCookingEnergy) * Days$ /1,000

Where:

ΔDailyIdleEnergy = (1,200 * ((16 – 15/60) – 150 / 65)) - (800 * ((16 – 15/60) – 150 / 70))
= 5,245 Wh

ΔDailyPreheatEnergy = (2.4 - 1.9) * 1,000
= 500 Wh

ΔDailyCookingEnergy = (150 * 167/ 0.75) - (150 * 167/ 0.83)
= 3,219 Wh

ΔkWh = (5,245 + 500 + 3,219) * 365.25 / 1,000
= 3,274.2 kWh

[Electric Large Vat using defaults = 2,697.6 kWh]

For example, an ENERGY STAR standard-sized gas fryer, using default values from the calculation above, would save:

ΔTherms = $(\Delta DailyIdleEnergy + \Delta DailyPreheatEnergy + \Delta DailyCookingEnergy) * Days$ /100,000

Where:

ΔDailyIdleEnergy = (14,000 * ((16 – 15/60) – 150 / 60)) - (9,000 * ((16 – 15/60) – 150 / 65))
= 64,519 Btu/day

ΔDailyPreheatEnergy = 18,500 – 16,000
= 2,500 Btu/day

ΔDailyCookingEnergy = (150 * 570/ 0.35) - (150 * 570/ 0.50)
=73,286 Btu/day

ΔTherms = (64,519 + 2,500 + 73,286) * 365.25 / 100,000
= 512.5 therms

[Gas Large Vat using defaults = 420.6 therms]

An ENERGY STAR standard-sized electric fryer compared to baseline gas fryer assuming default values from above would save.

SiteEnergySavings (MMBTUs) = $[GasConsumptionReplaced] - [ElectricConsumptionAdded]$

= $[(DailyIdleEnergy_{GasBase} + DailyPreheatEnergy_{GasBase} + DailyCookingEnergy_{GasBase}) * 1/1{,}000{,}000 * Days] -$

$[(DailyIdleEnergy_{ElecEE} + DailyPreheatEnergy_{ElecEE} + DailyCookingEnergy_{ElecEE}) * 3.412/1{,}000{,}000 * Days]$

DailyIdleEnergy$_{GasBase}$ = (14,000 * ((16 – 15/60) – 150 / 60))

= 185,500 btu

DailyPreheatEnergy$_{GasBase}$ = 18,500 btu

DailyCookingEnergy$_{GasBase}$ = (150 * 570/ 0.35)

= 244,286 btu

DailyIdleEnergy$_{ElecEE}$ = (800 * ((16 – 15/60) – 150 / 70))

= 10,886 Wh

DailyPreheatEnergy$_{ElecEE}$ = 1.9 * 1,000

= 1,900 Wh

DailyCookingEnergy$_{ElecEE}$ = (150 * 167/ 0.83)

= 30,181 Wh

SiteEnergySavings (MMBTUs) = ((185,500 + 18,500 + 244,286) * 1/1,000,000 * 365.25) – ((10,886 + 1,900 + 30,181) * 3.412/1,000,000 * 365.25)

= 110 MMBtu

If supported by an electric utility: ΔkWh = ΔSiteEnergySavings * 1,000,000 / 3,412

= 110 * 1,000,000/3,412

= 32,239 kWh

[Using Large Vat defaults = 103 MMBtu or 30,188 kWh]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = $((\Delta DailyIdleEnergy + \Delta DailyPreheatEnergy + \Delta DailyCookingEnergy)/(1{,}000 * HOURS) * CF$

ΔkW = $-((DailyIdleEnergy_{ElecEE} + DailyPreheatEnergy_{ElecEE} + DailyCookingEnergy_{ElecEE})/(1{,}000 * HOURS) * CF$

Where:

CF =Summer Peak Coincidence Factor

= 0.90[265]

[265] Itron, Inc. 2005. 2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report. Prepared for Southern California Edison.

Other variables as defined above.

For example, an ENERGY STAR standard-sized electric fryer in a cafeteria, using default values from the calculation above, would save:

$$\Delta kW = (5{,}245 + 500 + 3{,}219)/(1000 * HOURS) * CF$$
$$= 8964 / (1000 * 16) * 0.9$$
$$= 0.504\ kW$$

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

$$\Delta Therms = [Gas\ Cooking\ Consumption\ Replaced]$$
$$= [(DailyIdleEnergy_{GasBase} + DailyPreheatEnergy_{GasBase} + DailyCookingEnergy_{GasBase}) * 1/100{,}000 * Days]$$

$$\Delta kWh = [Electric\ Cooking\ Consumption\ Added]$$
$$= -[(DailyIdleEnergy_{ElecEE} + DailyPreheatEnergy_{ElecEE} + DailyCookingEnergy_{ElecEE}) * Days/\ 1{,}000]$$

REVIEW DEADLINE: 1/1/2028

4.2.8 ENERGY STAR Griddle

DESCRIPTION

This measure applies to single or double-sided electric, natural gas fired, or dual fuel ENERGY STAR[266] griddles installed in a commercial kitchen. For dual fuel griddles, savings should be divided between electric and gas as described in the Fossil Fuel Savings section of this measure.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a single or double-sided natural gas, electric, or dual fuel ENERGY STAR griddle with a tested heavy load cooking energy efficiency of 70 percent (electric) 38 percent (gas) or greater and an idle energy rate of 2,650 Btu/hr per square foot of cooking surface or less, utilizing ASTM F1275. The griddle must have an Idle Energy Consumption Rate < 2,600 Btu/hr per square foot of cooking surface.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an existing natural gas or electric griddle that's not ENERGY STAR certified and is at end of use.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years.[267]

DEEMED MEASURE COST

The incremental capital cost for this measure is $0 for and electric griddle and $60 for a gas griddle.[268]

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

Summer Peak Coincidence Factor for measure is assumed to be 0.90.[269]

Algorithm

CALCULATION OF SAVINGS [270]

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS

Non-Fuel Switch Measures

The algorithm below applies to ENERGY STAR compared to baseline electric griddles:

$$\Delta\text{kWh} = (\Delta IdleEnergy + \Delta PreheatEnergy + \Delta CookingEnergy) * Days\ /1000$$

[266] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[267] Lifetime from ENERGY STAR Commercial Kitchen Equipment Calculator, Commercial Griddle Calculations, which cites reference as "FSTC research on available models, 2009".
[268] Measure cost from ENERGY STAR Commercial Kitchen Equipment Calculator, which cites reference as "EPA research on available models using AutoQuotes, 2010".
[269] Itron, Inc. 2005. 2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report. Prepared for Southern California Edison.
[270] Algorithms and assumptions derived from ENERGY STAR Griddle Commercial Kitchen Equipment Savings Calculator.

The algorithm below applies to ENERGY STAR compared to baseline gas griddles:

$$\Delta\text{Therms} = (\Delta IdleEnergy + \Delta PreheatEnergy + \Delta CookingEnergy) * Days\ /100{,}000$$

Fuel Switch/Electrification Measures:

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

$$\text{SiteEnergySavings (MMBTUs)} = [GasConsumptionReplaced] - [ElectricConsumptionAdded]$$

$$= [(DailyIdleEnergy_{GasBase} + DailyPreheatEnergy_{GasBase} + DailyCookingEnergy_{GasBase}) * 1/1{,}000{,}000 * Days] -$$

$$[(DailyIdleEnergy_{ElecEE} + DailyPreheatEnergy_{ElecEE} + DailyCookingEnergy_{ElecEE}) * 3.412/1{,}000{,}000 * Days]$$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported by:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

$$\Delta\text{DailyIdleEnergy} = [(Idle_{Base} * Width * Depth * (HOURSday - (LB/(PC_{Base} * Width * Depth) - (PreheatNumber_{Base} * PreheatTime_{Base}/60))] - [(Idle_{ENERGYSTAR} * Width * Depth * (HOURSday - (LB/(PC_{ENERGYSTAR} * Width * Depth) - (PreheatNumber_{ENERGYSTAR} * PreheatTime_{ENERGYSTAR}/60))]$$

$$\Delta\text{DailyPreheatEnergy} = (PreHeatNumber_{Base} * PreheatTime_{Base} / 60 * PreheatRate_{Base} * Width * Depth) - (PreheatNumber_{ENERGYSTAR} * PreheatTime_{ENERGYSTAR}/60 * PreheatRate_{ENERGYSTAR} * Width * Depth)$$

$$\Delta\text{DailyCookingEnergy} = (LB * EFOOD/ Eff_{Base}) - (LB * EFOOD/ Eff_{ENERGYSTAR})$$

$$\text{DailyIdle Energy}_{\text{GasBase}} = [(Idle_{BaseGas} * Width * Depth * (HOURSday - (LB/(PC_{BaseGas} * Width * Depth)) - (PreheatNumber_{Base} * PreheatTime_{Base}/60)]$$

$$\text{DailyPreheatEnergy}_{\text{GasBase}} = (PreheatNumber_{Base} * PreheatTime_{Base}/60 * PreheatRate_{BaseGas} * Width * Depth)$$

$$\text{DailyCooking Energy}_{\text{GasBase}} = (LB * EFOOD/ Eff_{BaseGas})$$

DailyIdle Energy$_{ElecEE}$ =$[(Idle_{ENERGYSTARElec} * Width * Depth * (HOURSday - (LB/(PC_{ENERGYSTARElec} * Width * Depth)) - (PreheatNumber_{ENERGYSTAR} * PreheatTime_{ENERGYSTAR}/60]$

DailyPreheat Energy$_{ElecEE}$ = $(PreheatNumber_{ENERGYSTAR} * PreheatTime_{ENERGYSTAR}/60 * PreheatRate_{ENERGYSTAR} * Width * Depth)$

DailyCooking Energy$_{ElecEE}$ = $(LB * EFOOD/ Eff_{ENERGYSTARElec})$

Where:

Idle$_{Base}$ = Idle energy rate of baseline griddle

= Actual or if unknown, use 400 W/h/sq ft for electric and 3,500 Btu/h/sq ft for gas

Idle$_{ENERGYSTAR}$ = Idle energy rate of ENERGY STAR griddle

= Actual or if unknown, use 320 W/h/sq ft for electric and 2,650 Btu/h/sq ft for gas

LB = Food cooked per day

= Actual or if unknown, use 100 pounds

= For dual fuel systems assume half electric and half gas or if unknown, use 50 pounds for electric and 50 pounds for gas

Width = Griddle Width

= Actual or if unknown, use 3 feet

Depth = Griddle Depth

= Actual or if unknown, use 2 feet

PC$_{Base}$ = Production Capacity base

= Actual or if unknown, use 35/6 = 5.83 pounds/hr/sq ft for electric and 25/6 = 4.17 pounds/hr/sq ft for gas

PC$_{ENERGYSTAR}$ = Production Capacity ENERGY STAR

= Actual or if unknown, use 40/6 = 6.67 pounds/hr/sq ft for electric and 45/6 = 7.5 pounds/hr/sq ft for gas

PreheatNumber$_{Base}$ = Number of preheats per day base

= Actual or if unknown, use 1

= For dual fuel systems assume half electric and half gas or if unknown, use .5 for electric and .5 for gas

PreheatNumber$_{ENERGYSTAR}$ = Number of preheats per day ENERGY STAR

= Actual or if unknown, use 1

= For dual fuel systems assume half electric and half gas or if unknown, use .5 for electric and .5 for gas

PreheatTime$_{Base}$ = preheat length base (mins)

= Actual or if unknown, use 15 minutes

PreheatTime$_{ENERGYSTAR}$ = preheat length ENERGY STAR (mins)

= Actual or if unknown, use 15 minutes

$PreheatRate_{Base}$ = preheat energy rate baseline

= Actual or if unknown, use 16000/6 = 2,667 W/sq ft for electric and 84,000/6 = 14,000 btu/h/sq ft

$PreheatRate_{ENERGYSTAR}$ = preheat energy rate ENERGY STAR

= Actual or if unknown, use 8000/6 = 1,333 W/sq ft for electric and 60,000/6 = 10,000 btu/h/sq ft for gas

EFOOD = ASTM energy to food

= 139 w/pound for electric and 475 btu/pound for gas

EffBase = Cooking Efficiency Baseline

= Actual or if unknown, use 65% for electric and 32% for gas

$Eff_{ENERGYSTAR}$ = Cooking Efficiency ENERGY STAR

= Actual or if unknown, use 70% for electric and 38% for gas

HOURSday = Average Daily Operation

= Actual or if unknown, use 12 hours

Days = Annual days of operation

= Actual or if unknown, use 365.25 days a year

For dual fuel griddles, use the specified assumptions above to calculate halved savings for both electric and gas savings components for a sum of total savings.[271]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Non-fuel switch measures:

$$kW = (\Delta IdleEnergy + \Delta PreheatEnergy + \Delta CookingEnergy) / (1{,}000 * HoursDay) * CF$$

Fuel switch measures:

$$kW = -((DailyIdleEnergy_{ElecEE} + DailyPreheatEnergy_{ElecEE} + DailyCookingEnergy_{ElecEE}) / (1{,}000 * HoursDay) * CF$$

For dual fuel griddles, use the specified assumptions to calculate halved savings for non-fuel switch and fuel switch measures for a sum of total savings.

Where:

CF =Summer Peak Coincidence Factor

= 0.90[272]

[271] Duel fuel griddles are usually electric top plates and gas bottom plates, often used by fast food restaurants. As per DOE workpaper "Energy Savings Potential and RD&D Opportunities for Commercial Building Appliances (2015 Update)" these models have a “second heating plate that is lowered on top of the food and used to simultaneously cook both sides." It therefore is reasonable to assume half savings are attributed to gas v electric.

[272] Itron, Inc. 2005. 2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report. Prepared for Southern California Edison.

For example, an ENERGY STAR griddle in a cafeteria with a tested heavy load cooking energy efficiency of 70 percent or greater and an idle energy rate of 320 W per square foot of cooking surface or less would save

= (2000+1527+3583)/(1000 * 12) * 0.9

= 0.533 kW

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

WATER IMPACT DESCRIPTIONS AND CALCULATION

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms $= [Gas\ Cooking\ Consumption\ Replaced]$

$=[(DailyIdleEnergy_{GasBase} + DailyPreheatEnergy_{GasBase} + DailyCookingEnergy_{GasBase}) * 1/100{,}000 * Days]$

ΔkWh $= [Electric\ Cooking\ Consumption\ Added]$

$=- [(DailyIdleEnergy_{ElecEE} + DailyPreheatEnergy_{ElecEE} + DailyCookingEnergy_{ElecEE}) * Days\ /\ 1{,}000]$

4.2.9 ENERGY STAR Hot Food Holding Cabinets

DESCRIPTION

This measure applies to electric ENERGY STAR[273] hot food holding cabinets (HFHC) installed in a commercial kitchen.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be an ENERGY STAR certified HFHC.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an electric HFHC that's not ENERGY STAR certified and at end of life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years.[274]

DEEMED MEASURE COST

The incremental capital cost for this measure is $1,000.[275]

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

Summer Peak Coincidence Factor for measure is assumed to be 0.90.[276]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Custom calculation below, otherwise use deemed values of 545 kWh.[277]

$$\Delta kWh = \frac{(IdleEnergyRateBase - IdleEnergyRateES) * HOURSday * Days}{1000}$$

Where:

IdleEnergyRateBase = Custom, otherwise

= 30 * V

V = Volume of HFHC (cubic feet)

= Custom, otherwise assume 15 cu ft

[273] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[274] Lifetime from ENERGY STAR Commercial Kitchen Equipment Calculator, updated March 2024, Hot Food Holding Cabinet Calculations, which cites reference as "FSTC research on available models, 2009".

[275] Measure cost from ENERGY STAR Commercial Kitchen Equipment Calculator, updated March 2024, which cites reference as "EPA research using AutoQuotes, 2020".

[276] Itron, Inc. 2005. 2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report. Prepared for Southern California Edison.

[277] Algorithms and assumptions derived from ENERGY STAR Commercial Kitchen Equipment Savings Calculator, updated 2024.

HOURSday = Average Daily Operation

= custom or if unknown, use 9 hours

Days = Annual days of operation

= custom or if unknown, use 365.25 days a year

IdleEnergyRateES = Custom, otherwise assume maximum ENERGY STAR Idle Energy Rate presented below. If volume is unknown assume 15 cu ft, resulting in 284W:

Cabinet Volume (cu ft)	Power (W)
V < 13	21.5 * V
13 ≤ V < 28	2*V+254
28 ≤ V	3.8*V+203.5

For example, if a full size HFHC, with a volume of 15 cubic ft, is installed the measure would save:

ΔkWh = ((15*30)-(2*V+254))*9*365.25/1,000

= (450 – 284)*9*365.25 /1,000

= 546 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh}{Hours} * CF$$

Where:

Hours = Hoursday *Days

= If unknown, use 9 * 365.25 = 3287 hours

CF =Summer Peak Coincidence Factor

= 0.90[278]

For example, if a full size HFHC, with a volume of 15 cubic feet, is installed in a cafeteria the measure would save:

= 545 kWh / (9*365.25)* 0.9

=0 .1492 kW

4.2.10 Ice Maker

DESCRIPTION

This measure relates to the installation of a new ENERGY STAR[279] qualified commercial ice machine. The ENERGY STAR label applied to air-cooled, cube-type machines including ice-making head, self-contained, and remote-condensing units. This measure could relate to the replacing of an existing unit at the end of its useful life, or the installation of a new system in a new or existing building.

This measure was developed to be applicable to the following program types: TOS and NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be a new commercial ice machine meeting the minimum ENERGY STAR efficiency level standards.

ENERGY STAR Requirements (Version 3.0, Effective January 28, 2018)

ENERGY STAR Requirements for Air-Cooled Batch-Type Ice Makers			
Equipment Type	**Applicable Ice Harvest Rate Range (lbs of ice/24 hrs)**	**ENERGY STAR Energy Consumption Rate (kWh/100 lbs ice)**	**Potable Water Use (gal/100 lbs ice)**
IMH	H < 300	≤ 9.20 - 0.01134H	≤ 20.0
	300 ≤ H < 800	≤ 6.49 - 0.0023H	
	800 ≤ H < 1500	≤ 5.11 - 0.00058H	
	1500 ≤ H ≤ 4000	≤ 4.24	
RCU	H < 988	≤ 7.17 – 0.00308H	≤ 20.0
	988 ≤ H ≤ 4000	≤ 4.13	
SCU	H < 110	≤ 12.57 - 0.0399H	≤ 25.0
	110 ≤ H < 200	≤ 10.56 - 0.0215H	
	200 ≤ H ≤ 4000	≤ 6.25	
ENERGY STAR Requirements for Air-Cooled Continuous-Type Ice Makers			
Equipment Type	**Applicable Ice Harvest Rate Range (lbs of ice/24 hrs)**	**ENERGY STAR Energy Consumption Rate (kWh/100 lbs ice)**	**Potable Water Use (gal/100 lbs ice)**
IMH	H < 310	≤ 7.90 – 0.005409H	≤ 15.0
	310 ≤ H < 820	≤ 7.08 – 0.002752H	
	820 ≤ H ≤ 4000	≤ 4.82	
RCU	H < 800	≤ 7.76 – 0.00464H	≤ 15.0
	800 ≤ H ≤ 4000	≤ 4.05	
SCU	H < 200	≤ 12.37 – 0.0261H	≤ 15.0
	200 ≤ H < 700	≤ 8.24 – 0.005429H	
	700 ≤ H ≤ 4000	≤ 4.44	

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline equipment is assumed to be a commercial ice machine meeting federal equipment standards established January 28, 2018.

[279] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 9 years.[280]

DEEMED MEASURE COST

When available, the actual cost of the measure installation and equipment shall be used. The incremental capital cost for this measure is $0 for Batch-Type and Continuous-Type[281].

LOADSHAPE

Loadshape C23 - Commercial Refrigeration

COINCIDENCE FACTOR

The Summer Peak Coincidence Factor is assumed to equal 0.937.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWH = [(kWh_{base} - kWh_{ee}) / 100] * (DC * H) * 365.25$$

Where:

kWh_{base} = maximum kWh consumption per 100 pounds of ice for the baseline equipment

= calculated as shown in the table below using the actual Harvest Rate (H) of the efficient equipment[282].

kWh_{ee} = maximum kWh consumption per 100 pounds of ice for the efficient equipment

= actual if known. If unknown calculate as shown in the table below using the actual Harvest Rate (H) of the efficient equipment.

[280] Based on DOE Technical Support Document, 2014 as recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.

[281] Incremental costs from ENERGY STAR Commercial Kitchen Equipment Savings Calculator. Calculator cites EPA research using AutoQuotes, 2016.

[282] Use the appropriate equipment type baseline and ice harvest rate range when calculating the savings for a CEE Tier Advanced ice maker.

Energy Consumption of Air-Cooled Batch-Type Ice Makers			
Ice Maker Type	**Applicable Ice Harvest Rate Range (lbs of ice/24 hrs)**	**kWh_{Base}**	**kWh_{ESTAR}**
IMH	H < 300	10-0.01233H	≤ 9.20 - 0.01134H
	300 ≤ H < 800	7.05-0.0025H	≤ 6.49 - 0.0023H
	800 ≤ H < 1500	5.55-0.00063H	≤ 5.11 - 0.00058H
	1500 ≤ H ≤ 4000	4.61	≤ 4.24
RCU	H < 988	7.97-0.00342H	≤ 7.17 – 0.00308H
	988 ≤ H ≤ 4000	4.59	≤ 4.13
SCU	H < 110	14.79-0.0469H	≤ 12.57 - 0.0399H
	110 ≤ H < 200	12.42-0.02533H	≤ 10.56 - 0.0215H
	200 ≤ H ≤ 4000	7.35	≤ 6.25
Energy Consumption of Air-Cooled Continuous-Type Ice Makers			
Equipment Type	**Applicable Ice Harvest Rate Range (lbs of ice/24 hrs)**	**kWh_{Base}**	**kWh_{ESTAR}**
IMH	H < 310	9.19-0.00629H	≤ 7.90 – 0.005409H
	310 ≤ H < 820	8.23-0.0032H	≤ 7.08 – 0.002752H
	820 ≤ H ≤ 4000	5.61	≤ 4.82
RCU	H < 800	9.7-0.0058H	≤ 7.76 – 0.00464H
	800 ≤ H ≤ 4000	5.06	≤ 4.05
SCU	H < 200	14.22-0.03H	≤ 12.37 – 0.0261H
	200 ≤ H < 700	9.47-0.00624H	≤ 8.24 – 0.005429H
	700 ≤ H ≤ 4000	5.1	≤ 4.44

100 = conversion factor to convert kWhbase and kWhee into maximum kWh consumption per pound of ice.

DC = Duty Cycle of the ice machine

= 0.57[283]

H = Harvest Rate (pounds of ice made per day)

= Actual installed

365.35 = days per year

For example, a batch ice machine with an ice making head producing 450 pounds of ice would save

ΔkWH = [(5.9 – 5.5) / 100] * (0.57 * 450) * 365.25

= 440 kWh

[283]Duty cycle varies considerably from one installation to the next. TRM assumptions from Vermont, Wisconsin, and New York vary from 40 to 57%, whereas the ENERGY STAR Commercial Ice Machine Savings Calculator assumes a value of 75%. A field study of eight ice machines in California indicated an average duty cycle of 57% ("A Field Study to Characterize Water and Energy Use of Commercial Ice-Cube Machines and Quantify Saving Potential", Food Service Technology Center, December 2007). Furthermore, a report prepared by ACEEE assumed a value of 40% (Nadel, S., Packaged Commercial Refrigeration Equipment: A Briefing Report for Program Planners and Implementers, ACEEE, December 2002). The value of 57% was utilized since it appears to represent a high quality data source.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = $\Delta kWh \ / \ (HOURS \ * \ DC) \ * \ CF$

Where:

HOURS = annual operating hours

= 8766[284]

CF = 0.937

For example, an ice machine with an ice making head producing 450 pounds of ice would save

ΔkW = 440/(8766 * 0.57) * .937

= 0.083 kW

FOSSIL FUEL SAVINGS

N/A

WATER IMPACT DESCRIPTIONS AND CALCULATION

While the ENERGY STAR labeling criteria require that certified commercial ice machines meet certain "maximum potable water use per 100 pounds of ice made" requirements, such requirements are intended to prevent equipment manufacturers from gaining energy efficiency at the cost of water consumptions. A review of the AHRI Certification Directory[285] indicates that approximately 81% of air-cooled, cube-type machines meet the ENERGY STAR potable water use requirement. Therefore, there are no assumed water impacts for this measure.

4.2.11 High Efficiency Pre-Rinse Spray Valve

DESCRIPTION

Pre-rinse spray valves use a spray of water to remove food waste from dishes prior to cleaning in a dishwasher. More efficient spray valves use less water thereby reducing water consumption, water heating cost, and waste water (sewer) charges. Pre-rinse spray valves include a nozzle, squeeze lever, and dish guard bumper. Pre-rinse spray valves are manually operated, and the frequency of use depends on the volume of dirty dishes washed at a facility. The primary impacts of this measure are water savings. Reduced hot water consumption saves either natural gas or electricity, depending on the type of energy the hot water heater uses.

This measure was developed to be applicable to the following program types: TOS, EREP, KITS and DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the new or replacement pre-rinse spray nozzle must have a maximum flow rate that meets program requirements.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment flow rate depends on program type. For TOS, the baseline equipment is a new pre-rinse spray valve with a maximum flow rate of 1.23 gpm or less.[286] For EREP and DI, the baseline equipment is an existing pre-rinse spray valve with an assumed flow rate of 2.14 gpm or less.[287]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 5 years.[288]

DEEMED MEASURE COST

When available, the actual cost of the measure (including labor where applicable) should be used. If unknown, the incremental cost of this measure for TOS programs is assumed to be $21.[289] For EREP, KITS and DI programs, the total installed cost is assumed to be $88.[290]

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

N/A

[286] Baseline for TOS programs is calculated using the maximum flow rate for each product class in 10 CFR 431.266, Energy Efficiency Program for Certain Commercial and Industrial Equipment weighted by estimated 2018 shipments for each product class from Table 3.6.1: U.S. DOE, "Technical Support Document: Energy Efficiency Program for Consumer Products and Commercial and Industrial Equipment: Commercial Prerinse Spray Valves," December 2015.
[287] Average flow rate of spray valve replaced through direct install programs from DNV-GL, "Impact Evaluation of National Grid Rhode Island C&I Prescriptive Gas Pre-Rinse Spray Valve Measure – Final Report," September 30, 2014, page 6-6.
[288]Measure life from U.S. DOE, "Technical Support Document: Energy Efficiency Program for Consumer Products and Commercial and Industrial Equipment: Commercial Prerinse Spray Valves," December 2015, page 8-13."
[289]Incremental measure cost based on CA eTRM Low-Flow Pre-Rinse Spray Valve Measure SWFS013-04, updated November 13, 2024.
[290] Total installed cost is the full equipment cost from CA eTRM Low-Flow Pre-Rinse Spray Valve Measure SWFS013-04, updated November 13, 2024.It is assumed that programs typically install spray valves only when other kitchen equipment is also being installed, and therefore, there are no additional labor costs associated with spray valve installations.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS (NOTE WATER SAVINGS MUST FIRST BE CALCULATED)

$$\Delta kWH = \frac{\Delta Water\ (gallons) * 8.33 * 1 * (Tout - Tin) * (\frac{1}{Eff_Elec} 1/EFF_Elec)}{3{,}412} * FLAG$$

Where:

ΔWater (gallons)	= amount of water saved as calculated below
8.33	= specific mass in pounds of one gallon of water (lbm/gal)
1	= Specific heat of water: 1 Btu/lbm/°F
Tout	= Water Heater Outlet Water Temperature
	= custom, otherwise assume Tin + 70°F temperature rise from Tin[291]
Tin	= Inlet Water Temperature
	= custom, otherwise assume 50.7°F [292]
EFF_Elec	= Efficiency of electric water heater supplying hot water to pre-rinse spray valve
	=custom, otherwise assume 98%[293]
Flag	= 1 if electric or 0 if gas

Time of Sale: For example, a new spray nozzle with 0.98 gal/min flow replacing a nozzle with 1.23 gal/min flow at a large institutional establishments with a cafeteria with 70 degree temperature rise of water used by the pre-rinse spray valve that is heated by electric hot water saves annually :

ΔkWH = 14,040 * 8.33 * 1 * ((70+50.7) – 50.7) * (1/.98) /3,412 * 1

= 2,448kWh

Retrofit: For example, a new spray nozzle with 0.98 gal/min flow replacing a nozzle with 2.14 gal/min flow at a large institutional establishments with a cafeteria with 70 degree temperature rise of water used by the pre-rinse spray valve that is heated by electric hot water equals:

ΔkWH = 65,146 * 8.33 * 1 * ((70+ 50.7) – 50.7) * (1/.98) /3,412 * 1

=11,360 kWh

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWhwater = \frac{\Delta Water\ (gallons)}{1{,}000{,}000} * Ewater\ total$$

Where:

[291] If unknown, assume a 70 degree temperature rise from Tin per Food Service Technology Center calculator assumptions to account for variations in mixing and water heater efficiencies.

[292] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[293] Electric water heaters have recovery efficiency of 98%, as sourced from available products on the AHRI Certification Directory.

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

=5,010[294]

Time of Sale: For example, a new spray nozzle with 0.98 gal/min flow replacing a nozzle with 1.23 gal/min flow at a large institutional establishment with a cafeteria equals

ΔWater (gallons) = (1.23 – 0.98) * 60 * 3 * 312

= 14,040 gal/yr

ΔkWh_{water} = 14,040/1,000,000*5,010

= 70 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

$$\Delta Therms = \frac{\Delta Water\ (gallons) * 8.33 * 1 * (Tout - Tin) * (\frac{1}{Eff_Gas} 1/EFF_Gas)}{100{,}000} * (1 - FLAG)$$

Where (new variables only):

EFF_Gas = Efficiency of gas water heater supplying hot water to pre-rinse spray valve

= custom, otherwise assume 80%[295]

Time of Sale: For example, a new spray nozzle with 0.98 gal/min flow replacing a nozzle with 1.23 gal/min flow at a large institutional establishments with a cafeteria with 70 degree temperature of water used by the pre-rinse spray valve that is heated by fossil fuel hot water saves annually:

ΔTherms = 14,040 * 8.33 * 1 * ((70+50.7) - 50.7) * (1/0.80)/100,000 * (1-0)

= 102 Therms

Retrofit: For example, a new spray nozzle with 0.98 gal/min flow replacing a nozzle with 2.14 gal/min flow at a busy large institutional establishments with a cafeteria with 70 degree temperature rise of water used by the pre-rinse spray valve that is heated by fossil fuel hot water saves annually:

ΔTherms = 65,146 * 8.33 * 1 * ((70+50.7) - 50.7) * (1/0.80)/100,000 * (1-0)

=475 Therms

WATER IMPACT CALCULATION[296]

$$\Delta Water\ (gallons) = (FLObase - FLOeff) * 60 * HOURSday * DAYSyear * ISR$$

Where:

FLObase = Base case flow in gallons per minute, or custom (Gal/min)

[294] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

[295] IECC 2015, Table C404.2, Minimum Performance of Water-Heating Equipment

[296] In order to calculate energy savings, water savings must first be calculated

Time of Sale	Direct Install
1.23 gal/min[297]	2.14 gal/min[298]

FLOeff = Efficient case flow in gallons per minute or custom (Gal/min)

= 0.98 gal/min[299]

60 = Minutes per hour

HOURSday = Hours per day that the pre-rinse spray valve is used at the site, custom, otherwise:[300]

Application	Hours/day
Small, quick- service restaurants	1
Medium-sized casual dining restaurants	1.5
Large institutional establishments with cafeteria	3

DAYSyear = Days per year pre-rinse spray valve is used at the site, custom, otherwise 312 days/yr based on assumed 6 days/wk x 52 wk/yr = 312 day/yr.

ISR = in-service-rate, the percentage of units actually installed. For kits programs, if survey data is unavailable, use 0.466[301]. For all other programs use 1.0.

Time of Sale: For example, a new spray nozzle with 0.98 gal/min flow replacing a nozzle with 1.23 gal/min flow at a large institutional establishment with a cafeteria equals

= (1.23 – 0.98) * 60 * 3 * 312

= 14,040 gal/yr

Retrofit: For example, a new spray nozzle with 0.98 gal/min flow replacing a nozzle with 2.14 gal/min flow at a large institutional establishments with a cafeteria equals

= (2.14 – 0.98) * 60 * 3 * 312

= 65,146 gal/yr

Custom calculation below, otherwise use deemed value of 707 therms based on default values.[304]

$$\Delta Therms = \frac{(\Delta PreheatEnergy + \Delta CookingEnergy) * Days}{100{,}000}$$

$$\Delta\text{PreheatEnergy} = (PreheatRate_{Base} - PreheatRate_{EE}) * Preheats * \frac{PreheatTime}{60}$$

$$\Delta\text{CookingEnergy} = (InputRate_{Base} - InputRate_{EE}) * (Duty * Hours)$$

Where:

[302] Lifecycle determined from Food Service Technology Center Gas Broiler Life-Cycle Cost Calculator and from FSTC Broiler Technology Assessment.
[303] See 'Arkansas Deemed TRM Table for GasFoodService.xls' from v3.0 Arkansas Technical Reference Manual.
[304] Assumptions derived from Food Service Technology Center Gas Broiler Life-Cycle Cost Calculator and from FSTC Broiler Technology Assessment, Section 4: Broilers.

Days = Annual days of operation
= Custom or if unknown, use 312 days per year[305]
100,000 = Btu to therms conversion factor
$PreheatRate_{Base}$ = Preheat energy rate of baseline charbroiler
= 64,000 Btu/hr
$PreheatRate_{EE}$ = Preheat energy rate of infrared charbroiler
= Custom or if unknown, use 54,000 Btu/hr
Preheats = Number of preheats per day
= Custom or if unknown, use 1 preheat per day
PreheatTime = Length of one preheat
= Custom or if unknown, use 15 minutes per preheat[306]
60 = Minutes to hours conversion factor
$InputRate_{Base}$ = Input energy rate of baseline charbroiler
= 140,000 Btu/hr
$InputRate_{EE}$ = Input energy rate of infrared charbroiler
= Custom or if unknown, use 105,000 Btu/hr
Duty = Duty cycle of charbroiler (%)
= Custom or if unknown, use 80%[307]
Hours = Average daily hours of operation
= Custom or if unknown, use 8 hours per day

For example, using the default assumptions on the installation of an infrared charbroiler:

PreheatEnergy = (64,000 – 54,000) * 1 * (15 / 60)
= 2500 BTU/day
CookingEnergy = (140,000 – 105,000)*(.80*8)
= 224,000 BTU/day
ΔTherms = ((2,500 + 224,000) * 312) / 100,000
= 706.7 Therms

4.2.16 Kitchen Demand Ventilation Controls

DESCRIPTION

Installation of commercial kitchen demand ventilation controls that vary the ventilation based on cooking load and/or time of day.

IECC 2018 and 2021 specifies that Kitchen Demand Control Ventilation is a mandatory compliance pathway for systems over 5,000 CFM of exhaust airflow. As stated, each kitchen exhaust hood shall comply with one of the following:

- Not < 50% of all replacement air shall be transfer air that would otherwise be exhausted.
- Demand ventilation systems on not < 75% of the exhaust air that are configured to provide not less than 50% reduction in exhaust and replacement air system airflow rates including controls necessary to modulate airflow in response to appliance operation and maintain full capture and containment of smoke, effluent, and combustion products during cooking and idle.
- Listed energy recovery devices with a sensible heat recovery effectiveness not < 40% on not < 50% of the total exhaust airflow.

If one of these alternate compliance options is met, kitchen demand ventilation controls would not be required by code; however, in these situations the demand ventilation controls would be considered redundant and the energy savings would likely be reduced. As a result, this measure is only applicable to new kitchens/systems under 5,000 CFM of exhaust airflow.

This measure was developed to be applicable to the following program types: NC, RF, TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a control system that varies the exhaust rate of kitchen ventilation (exhaust and/or makeup air fans) based on the energy and effluent output from the cooking appliances (i.e., the more heat and smoke/vapors generated, the more ventilation needed). There are three main demand control ventilation systems available that can achieve this type of modulation:

- Temperature sensors only. These systems ramp ventilation up and down based solely on the temperature from the cooking activity as measured in the ductwork or capture tank of the hood.
- Temperature and optical sensors. These systems offer the same functionality as systems with only temperature sensors plus the ability to change the ventilation rate based on the presence of smoke or steam.
- Temperature and infrared cooking sensors. These systems offer the same functionality as systems with only temperature sensors plus the ability to measure ventilation up and down based on when cooking starts.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is kitchen ventilation that has constant speed ventilation motor.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years.[329]

DEEMED MEASURE COST

The incremental capital cost for this measure is:[330]

[329] "Commercial Kitchen Ventilation: An Energy Efficiency Program Administrator's Guide to Demand Control Ventilation", CEE, October 2010 (pg. 9). The 20-year measure life estimate is based on interviews with manufacturer and industry experts.
[330] The incremental costs were derived from Southern California Edison (SCE) program data on 72 demand control kitchen ventilation project installations between 2013 and 2017 (see;

Measure Category	Incremental Cost $/HP of Fan
DVC Control Retrofit	$1,992
DVC Control New	$1,180

Loadshape C23 - Commercial Ventilation

COINCIDENCE FACTOR

The measure has deemed peak kW savings therefore a coincidence factor does not apply.

Algorithm

CALCULATION OF SAVINGS

Annual energy use was based on monitoring results from five different types of sites, as summarized in PG&E Food Service Equipment work paper.

ELECTRIC ENERGY SAVINGS

kWh savings are assumed to be 4,423 kWh per horsepower of the fan.[331]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

kW savings are assumed to be 0.551 kW per horsepower of the fan.[332]

FOSSIL FUEL SAVINGS

$$\Delta\text{Therms} = CFM * HP * Annual\ Heating\ Load\ /(Eff(heat) * 100{,}000)$$

Where:

CFM = the average airflow reduction with ventilation controls per hood

= 430 cfm/HP[333]

HP = actual if known, otherwise assume 9.65 HP[334]

Annual Heating Load = Annual heating energy required to heat fan exhaust make-up air, Btu/cfm dependent on location:[335]

Zone	Annual Heating Load, Btu/cfm
1 (Rockford)	46,627

"SCE13CC008._Exhaust_Hood_DCKV_Exhaust_CFM_and_Cost_Field_Data.xlsx"). For reference, the baseline measure costs were factored out accordingly, being obtained from costs for five kitchen exhaust fans from RSMeans online in 2017. For more detail on the source of these cost estimates, please see the California eTRM – Exhaust Hood Demand Controlled Ventilation, Commercial measure (SWFS012-01), March 4, 2020.

[331] Based on data provided in Southern California Edison Workpaper "Commercial Kitchen Exhaust Hoods Demand Controlled Ventilation, June 11, 2014..

[332] Based on data provided in Southern California Edison Workpaper "Commercial Kitchen Exhaust Hoods Demand Controlled Ventilation, June 11, 2014. Normalized demand reduction over 11 sites was 0.612 kW/HP. Applying a 0.9 CF results in a coincident demand reduction of 0.551 kW/HP.

[333] Based on data provided in PGE Workpaper, Commercial Kitchen Demand Ventilation Controls, PGECOFST116, June 1, 2009. See 'Kitchen DCV.xls' for details.

[334] Average of 72 study sites in Southern California Edison Workpaper "Commercial Kitchen Exhaust Hoods Demand Controlled Ventilation, June 11, 2014.

[335] Hours are from Commercial Kitchen Demand Ventilation Controls (Average 17.8 hours a day 4.45 am to 10.30 pm). Savings for all locations were calculated using NCEI 15-yr HDD data, and properties of air at atmospheric conditions and room temperature. See reference file "Kitchen DCV rev2.0.xlsx"

Zone	Annual Heating Load, Btu/cfm
2-(Chicago)	39,688
3 (Springfield)	33,597
4-(Belleville)	20,991
5-(Marion)	22,128

Eff(heat) = Heating Efficiency

= actual if known, otherwise assume 80%[336]

100,000 = conversion from Btu to Therm

For example, a kitchen hood in Rockford, IL with a 9.65 HP ventilation motor

ΔTherms = 430 * 9.65*46,627 / (0.80 * 100,000)

= 2,418 Therms

4.2.17 Pasta Cooker

DESCRIPTION

This measure applies to natural gas fired dedicated pasta cookers as determined by the manufacturer and installed in a commercial kitchen.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a new natural gas fired pasta cooker.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an existing natural gas fired stove where pasta is cooked in a pan.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12.[337]

4.2.19 ENERGY STAR Electric Convection Oven – Removed in v11, consolidated with 4.2.5 ENERGY STAR Convection Oven

4.2.20 Efficient Dipper Wells

DESCRIPTION

Various commercial food establishments utilize dipper wells that continuously run fresh water over utensils. One example is an ice cream shop that places the ice cream scooper in the dipper well, in order to keep them clean and avoid cross-mixing of flavors. Some restaurants may utilize a dipper well to store potato slicers and butter-ball scoopers. Coffee shops often utilize a dipper well for storage of drink thermometers and mixing spoons. Bars may utilize a dipper well for storage of mixing spoons, strainers, ice tongs, and other utensils. Dipper wells may also be found in grocery stores, school cafeterias, and other institutional kitchens.

Commercial kitchen equipment vendors have developed water-efficient dipper well designs which eliminate the continuous water flow. The efficient design recirculates the water in the well rather than continuously adding fresh water. For bacteriological control some designs utilize a chemical disinfectant (i.e., bleach) and some utilize ozone.

The calculated water savings (in gallons/year) will, in turn, be used to calculate electricity savings (in kWh/year) after applying the appropriate energy factor.

Heated dipper wells are not included in this characterization as the electric penalty associated with the electric resistance heating removes all potential electric savings due to water characterization.

This measure was developed to be applicable to the following program types; EREP and TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is assumed to be a dipper well that does not continuously run. One type of water-efficient dipper well design recirculates the water in the basin, rather than continuously adding fresh water. The efficient design will employ chemical or ozone sanitation.

Other types of water-efficient dipper well utilize a spatula or shower, where water is only applied to the surface of the utensil when a pressure switch is activated. The dimensions of water-efficient dipper wells will vary, depending on the number of utensils that need to be handled. The flow rate of the spigot is similar between the baseline equipment and the efficient equipment. However, that flow rate only occurs when the well initially fills up or the pressure switch is activated.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be a dipper well providing continuously running fresh water to the utensils in the basin. As a result, there is a concurrent stream of wastewater that is continuously sent to the sewer. The dipper well typically will run during the hours of operation for the restaurant or bar. Some dipper wells will also be left on during the night when the establishment is closed.

Many dipper wells consist of two concentric tanks. Water flows into the inner tank and overflows through the perforations at the top to the outer tank, which is connected to the sewer drain. Other designs utilize just one tank, with some other means of overflow drainage to the sewer.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[348]

[348] Alignment with existing dipper well program measure lives in California. Dipper Well Replacement Field Evaluation Report, Frontier Energy, November 2017.
https://fishnick.com/publications/fieldstudies/Dipper_Well_Replacement_Field_Evaluation_ICP.pdf

DEEMED MEASURE COST

The cost for this measure is assumed to be $450 for Early Replacement or $300 for Time of Sale. The typical material cost for an efficient dipper well system is approximately $150 to $350.[349] The typical material cost for a baseline dipper well system is approximately $100 to $200.[350] Full installation costs, including plumbing materials, labor, and any associated controls, should be used for screening purposes.

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

N/A

Algorithm

CALCULATION OF SAVINGS

Energy savings from the efficient dipper well systems are the result of reduced water consumption. There are indirect electric energy savings from reduced potable water treatment and wastewater treatment energy inputs.

ELECTRIC ENERGY SAVINGS

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

The electric energy savings are based indirectly on the reduced electricity usage used to provide the potable water and treat the wastewater. By applying an "Energy Factor", the water savings (in gallons/year) can be converted to electricity savings (in kWh/year). This "Energy Factor" considers the electric energy requirements of potable water treatment plants, potable water distribution, wastewater treatment plants, and wastewater distribution.

$$\Delta kWh_{water} = \Delta Water\ (gallons) \ / \ 1{,}000{,}000 \ * \ Ewater\ total$$

Where:

Ewater total = IL Total Water Energy Factor (kWh/Million Gallons)

=5,010[351]

[349] Google Shopping search for the term "water efficient dipper well". Results include the "Conservewell" from KaTom Restaurant Supply for $300.

[350] Google Shopping search for the term "dipper well system". Results show various baseline models that range from $100 to $200.

[351] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

For example,

BAWU = $(DWOH * AO) / (TFOG\ x\ 1\ hour/60\ min)$

= $[16\ hours/day] * [365\ day/year]$

$[0.5\ gal/min] * [1\ hour/60\ min]$

= $175{,}200\ gal/year$

ECAWU = $3{,}650\ gal/year$

ΔWater = $BAWU - ECAWU$

= $175{,}200\ gal/year - 3{,}650\ gal/year$

= $171{,}550\ gal/year$

ΔkWhwater = $\Delta Water\ /\ 1{,}000{,}000 * Ewater\ total$

= $(171{,}500\ gal.of\ water/year)\ /\ 1{,}000{,}000 * 5{,}010\ kWh/million\ gallons$

= $859\ kWh/year$

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

N/A

WATER IMPACT DESCRIPTIONS AND CALCULATION

The methodology for quantifying the water savings involves a direct comparison of the baseline equipment to the efficient equipment. The baseline flow rate will typically be between 0.2 gpm to 1.0 gpm.[352] The actual flow rate of the baseline equipment should be directly measured. This can be accomplished by recording the time required to fill a 1-gallon container (minutes per gallon); taking the inverse of that value will give the water flow rate (gallons per minute). The number of hours per day that the spigot remains flowing should be determined. This is typically coincident with the operating hours of the establishment, but the spigot could remain flowing during off hours too.

The equation for calculating the baseline annual water usage is as follows:

BAWU = $[DWOH * AO) / [TFOG\ x\ (1\ hour/60\ min)]$

Where:

BAWU = $Baseline\ Annual\ Water\ Usage\ (gal/year)$

DWOH = $Dipper\ Well\ Operating\ Hours\ (hours/day)$

AO = $Annual\ Operations\ (days/year)$

TFOG = $Time\ to\ Fill\ One\ Gallon\ (min/gal)$

Estimating the efficient-case water consumption will require an understanding of how the dipper well will be used. If the efficient-case equipment utilizes a constantly circulating pool of chemically treated water, then the only water consumption is that required to fill the basin. Depending on the number of times that the basin is filled and emptied in a day, the annual water consumption for the efficient case can be calculated as follows:

ECAWU = $BV * BFPD * AO$

Where:

[352] Michael Slater and Amin Delagah, "Dipper Well Replacement Field Evaluation Report", Frontier Energy Report #50115-R0, November 2017. Prepared for the Metropolitan Water District of Southern California. http://www.bewaterwise.com/pdfs/ICP/2015ICP-DipperWellFrontierEnergy.pdf

ECAWU = Efficient Case Annual Water Usage (gal/year)

BV = Basin Volume (gal)

BFPD = Basin Fills Per Day (days-1)

AO = Annual Operations (days/year)

If the efficient-case equipment utilizes a 'shower' that only dispenses water when the pressure switch is activated, the amount of water consumption is dependent on the number of times the 'shower' is actuated and the length of each 'shower'. The Spigot Flow Rate should be similar to that of the baseline equipment (0.2 gal/min to 1.0 gal/min). However, that flow rate is only in effect for the duration that the pressure switch is pressed. This is referred to as the Time of Actuation, and it can generally be estimated as a few seconds per push. Furthermore, the number of times the shower is actuated in a day can be estimated by considering the customer sales volume of the establishment.

The annual water consumption for the efficient case can also be calculated as follows:

$$ECAWU = (SFR\ x\ TA\ x\ NAPD)\ /\ (60\ sec/min\ x\ AO)$$

Where:

ECAWU = Efficient Case Annual Water Usage (gal/year)

SFR = Spigot Flow Rate (gal/min)

TA = Time of Actuation (sec/push)

NAPD = Number of Actuations per Day (push/day)

AO = Annual Operations (days/year)

For the purposes of this measure, the Efficient Case daily water usage of 10 gal/day will be used [353]. At 365 days/year of usage, the ECAWU will be 3,650 gal/year.

Finally, the annual water savings per year can be calculated as follows:

$$\Delta Water = BAWU\ -\ ECAWU$$

Where:

ΔWater = Total Water Savings (gal/year)

BAWU = Baseline Annual Water Usage (gal/year)

ECAWU = Efficient Case Annual Water Usage (gal/year)

4.2.21 On-Demand Package Sealers – Provisional Measure

DESCRIPTION

This measure consists of the replacement of standard electric package sealers with new on-demand package sealers in a retail grocery store. The sealers are used for heat-sealing plastic-wrapped packages for retail sale. The typical baseline unit uses a 550-Watt heating element and 50 Watt heat sealing bar at about 280°F or greater and maintains that temperature unless the unit is turned off when not in use.[354] In practice, the units are frequently left on to avoid waiting for the bar to reach operating temperature. Qualifying units use on-demand heat bars or automatic controls that turn off the unit between uses. Different configurations and brands were tested for the baseline at two grocery store chains that included a total of 199 stores. [355] This measure applies to grocery store, convenience store, deli, bakery, butcher, and other commercial with a demonstrated business need.

This measure was developed to be applicable to the following program types: TOS, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The on-demand package sealer uses controls to turn the equipment off when it is not in use. The functionality of the baseline and on-demand system is similar. The on-demand package sealer operates similarly to the baseline but has a larger heating element. The on-demand package sealer utilizes an automatic control or pressure momentary switch control to power off the heating elements when the equipment is not in use. Controls for the on-demand unit allow the heating element to turn on only when the heating element is pushed down, or the product crosses the automatic controls. By applying pressure to the heating element or activating the automatic controls the on-demand unit engages a switch, which activates the 2,000-Watt heating element until the switch is disengaged, or for a maximum of 3 seconds. The efficient sealers use less energy overall by reducing standby electrical energy use. These machines come in stand-alone or table-top styles.

DEFINITION OF BASELINE EQUIPMENT

The baseline package sealer consists of a heating bar and a larger heating element and is rated at approximately 550 Watts and 0.50 kW, respectively. The heating bar is used to cut the wrapping film as it contacts the heating bar. The larger heating element is used to heat up the wrapping film. When the wrapping film is heated, the film sticks to a package to seal the product. With the conventional package sealer, both heating elements are controlled to keep a constant temperature of 280°F. The units are manually turned on and off. The baseline package sealers come in two styles, a stand-alone unit and a table-top unit.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[356]

DEEMED MEASURE COST

The deemed measure cost for this measure varies based on unit size and type. Please see the table[357] below for typical costs:

---

[354] Design & Engineering Services Customer Service Organization Southern California Edison, October 2012, Vacuum-Sealing and Packaging Machines For Food Service Applications Field Test Et10sce1450, pg 1.

[355] The October 2012 SCE field test (mentioned above) was a study based datalogger information over six weeks of units in 199 stores.

[356] Based on similar equipment types, as there is not a standard for shrink wrappers listed. The Illinois TRM v9's kitchen equipment measure lives range from 5-20 years. 70% of the kitchen equipment measures have a 12 year measure life, but half of these are gas-only measures. We used Efficient Dipper Wells' measure life of 10 years as both measures save energy by replacing continuously running equipment with equipment that only runs when needed. Both On-Demand Package Sealers and Efficient Dipper Wells also may have higher regular maintenance needs than the other Kitchen equipment - to prevent clogging.

[357] Commercial Vacuum Sealer costs – Manual (Baseline) & Automatic. Please see pdf of https://www.webstaurantstore.com/ data sets.

Equipment Category	Tabletop Unit	Floor Unit
Baseline	$2,492	$2,242
Efficient	$3,281	$12,208

LOADSHAPE

N/A

COINCIDENCE FACTOR

N/A

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = \left(\frac{(\text{Watts}_{\text{base}} * \text{HOU})}{1{,}000}\right) - \left(\left(\frac{(\text{Watts}_{\text{efficient}} * \text{HOU})}{1{,}000}\right) * (1 - \text{ESF})\right)$$

Where:

$\text{Watts}_{\text{base}}$ = Wattage of Existing Equipment's heating element
= If not known, use 600 W[358]

$\text{Watts}_{\text{efficient}}$ = Wattage of Proposed Efficient Equipment sealing element
= If not known, use 2,000 W[359]

HOU = Use known Hours of Use
= If hours not known, hours are selected from the fixture hours column of the Reference Table in Section 4.5 for each building type.

ESF = Energy Savings Factor
= If ESF not known, use 90% [360]

For example, a new on-demand package sealer replacing a baseline package sealer with unknown hours at a grocery store saves:

ΔkWh = ((600 * 5,468) / 1,000) – (((2,000 * 5,468) / 1,000) * (1 - 0.9))
= 2,187.2 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta\text{kW} = \frac{\Delta kWh}{HOU} * CF$$

[358] Design & Engineering Services Customer Service Organization Southern California Edison, October 2012, Vacuum-Sealing And Packaging Machines For Food Service Applications Field Test Et10sce1450 – Note: this was a study based datalogger information over six weeks of units in 199 stores.
[359] Ibid
[360] ESF assumes On-Demand Package Sealer is actively heating 10% of the Hours of Use. The ESF source assumption is that the On-Demand sealers will be in use an average of six minutes of every hour. Currently there is no logged data that captures the total amount of time the efficient machines run, however once we get that data is available from the program, this value will be updated.

Where:

CF = Coincident Factor, use 1.0.

For example, a new on-demand package sealer replacing a baseline package sealer with unknown hours at a grocery store saves:

ΔkWh = 2,187.2 / 5,468 * 1.0

= 0.40 kW

4.2.22 Automatic Conveyor Broiler

DESCRIPTION

This measure applies to natural gas fired energy efficient automatic conveyor broiler installed in a commercial kitchen. Conveyor broilers are one of the most energy intensive appliances in a commercial kitchen and energy efficient automatic conveyor broilers have potential to save energy while providing similar capacities and reducing the heat load in a kitchen[361].

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To be eligible for rebates, the energy efficient natural gas fired automatic conveyor broiler must have a catalyst and an input rate less than 80 kBtu/hr or a dual stage or modulating valve with a capability of throttling the input rate below 80 kBtu/hr[362].

Natural gas fired energy efficient automatic conveyor broilers equipped with electric bun grills and/or electric heating/warming elements are eligible for electric energy savings.

DEFINITION OF BASELINE EQUIPMENT

The base case is defined as natural gas fired automatic conveyor broiler capable of maintaining a temperature above 600^{o}F and an idle rate greater than the energy efficient replacement.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years[363].

DEEMED MEASURE COST

The incremental capital cost varies based on the conveyor width[364]:

Conveyor Width (in)	IMC
18in	$4,767
26in	$2,729
30in	$1,711

LOADSHAPE

N/A

COINCIDENCE FACTOR

Summer Peak Coincidence Factor for measure is 0.90[365].

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Natural gas fired energy efficient automatic conveyor broilers equipped with electric bun grills and/or electric heating/warming elements are eligible for electric energy savings.

$$\Delta kWh = kWHbase - kWheff$$

$$kWh = ElectricalIDLE(kW) * HoursDAY * Days$$

Where:

$Electrical_{IDLE}(kW)$ = Electrical Idle Energy Rate. See table below[366]. If known, use actual.

Conveyor Width (in)	Baseline Idle Energy Rate (kW)	EE Idle Energy Rate (kW)
<20in	1.84	0.20
20in -26in	1.35	0.37
>26in	4.80	1.15

$Hours_{DAY}$ = Daily Operating Hours. See table below. If known, use actual.

Location	$Hours_{DAY}$
Smaller restaurants; 2nd broiler in 24-hr restaurant	8 hours[367]
24 hour restaurant	23 hours[368]

Days = Days per year of operation

= Actual, default =

Location	Days
Smaller restaurants; 2nd broiler in 24-hr restaurant	312 days[369]
24 hour restaurant	363 days[370]

[366] Ibid.

[367] Assumptions derived from Food Service Technology Center Gas Broiler Life-Cycle Cost Calculator and from FSTC Broiler Technology Assessment, Section 4: Broilers.

[368] "California eTRM: Automatic Conveyor Broiler, Commercial", July 29th ,2021 https://www.caetrm.com/measure/SWFS017/02/

[369] Typical annual operating time from FSTC Broiler Technology Assessment, Table 4.3.

[370] "California eTRM: Automatic Conveyor Broiler, Commercial", July 29th ,2021 https://www.caetrm.com/measure/SWFS017/02/

For example, using the default assumptions on the installation of an efficient automatic conveyor broiler with a width less than 20 inches in a small restaurant:

kWh_{base} = 1.84 kW * 8 hours* 312 days

= 4,592.64 kWh

kWh_{eff} = 0.20 kW * 8 hours * 312 days

= 499.2 kWh

ΔkWh = 4592.64 kWh - 499.20 kWh

= 4,093.4 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh}{AnnualHours} * CF$$

Where:

ΔkWh = Annual kWh savings from measure as calculated above.

$$AnnualHours = HoursDAY * Days$$

= Actual. If unknown, use values listed above.

CF = Summer Peak Coincidence Factor

= 0.90

FOSSIL FUEL SAVINGS

$$\Delta Therms = \Delta Idle\ Energy + \Delta Preheat\ Energy + \Delta Cooking\ Energy$$

$$\Delta Idle\ Energy = \frac{(Idle\ EnergyBase - Idle\ EnergyEE)}{100{,}000}$$

$$Idle\ EnergyBase = (HoursDAY - (\frac{LB}{PCBase}) - (\frac{PRETimeBase}{60})) * IDLEBase$$

$$Idle\ EnergyEE = (HoursDAY - (\frac{LB}{PCEE}) - (\frac{PRETimeEE}{60})) * IDLEEE$$

Where:

LB = pounds of food cooked per day (lb/day)

PC = Production capacity (lbs/hr)

PRE_{TIME} = Preheat time (min/day)

IDLE = Idle energy rate (Btu/hr)

If known, use actual values, otherwise see table below:[371]

Conveyor Width (in)	LB (lb/day)		PC (Lbs/hr)		PreTIME (Min)		IDLE (Btu/hr)	
	Base	EE	Base	EE	Base	EE	Base	EE
<20in	75		29	21	10	29	54,500	28,000
20in - 26in	150		48	42	8	16	78,120	47,960

[371] "California eTRM: Automatic Conveyor Broiler, Commercial", November 13, 2024 https://www.caetrm.com/measure/SWFS017/04/

Conveyor Width (in)	LB (lb/day)		PC (Lbs/hr)		PreTIME (Min)		IDLE (Btu/hr)	
	Base	EE	Base	EE	Base	EE	Base	EE
>26in	110		90	86	22	12	104,000	57,000

$$\Delta Preheat\ Energy\ = \frac{(PREENERGYBase\ -\ PREENERGYEff)}{100{,}000}$$

Where:

PRE_{ENERGY} = Preheat energy (Btu)

$$\Delta Cooking\ Energy\ = \frac{(Cooking\ Energybase\ -\ Cooking\ EnergyEff)}{100{,}000}$$

$$Cooking\ Energybase\ = (\frac{LB}{PCBase})\ *\ CookingRateBase$$

$$Cooking\ EnergyEE\ = (\frac{LB}{PCEE})\ *\ CookingRateEE$$

$Cooking_{RateBase}$ = Baseline Cooking energy rate (Btu/hr)

$Cooking_{RateEE}$ = Efficient Cooking energy rate (Btu/hr)

If known, use actual values, otherwise see table below:[372]

Conveyor Width (in)	Pre_{ENERGY} (Btu)		$Cooking_{Rate}$ (Btu/hr)	
	Base	EE	Base	EE
<20in	11,500	13,500	55,000	28,500
20in - 26in	14,130	14,214	78,240	50,938
>26in	42,500	13,500	111,210	67,117

[372] "California eTRM: Automatic Conveyor Broiler, Commercial", November 13, 2024https://www.caetrm.com/measure/SWFS017/04/

For example, using the default assumptions on the installation of an efficient automatic conveyor broiler with a width less than 20 inches in a small restaurant:

Idle Energy$_{base}$	= (8 - (75 / 29) - (10 / 60)) * 54,500
	= 285,968.4 Btu
Idle Energy $_{EE}$	= (8 – (75 / 21) – (29 / 60)) * 28,000
	= 110,466.7 Btu
ΔIdle Enery	= (285,968.4 – 110,466.7) / 100,000
	= 1.75 Therms
ΔPreheat Energy	= (11,500 – 13,500) /100,000
	= -0.02 Therms
Cooking Energy$_{base}$	= (75 / 29) * 55,000
	=142,241.4 Btu
Cooking Energy$_{EE}$	= (75 / 21) * 28,500
	= 101,785.7 Btu
ΔCooking Energy	= (142,241.4-101,785.7)/100,000
	= 0.4 Therms
ΔTherms	= (1.75 + -0.02 + 0.40)
	= 2.1 Therms

4.2.23 Electric Deck Oven

DESCRIPTION

This measure applies to new electric deck ovens installed in a commercial kitchen which have minimum heavy load cooking efficiency and maximum idle rate standards based on lab testing following ASTM F1965-99 (2010).[373]

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The measure case is described as a new electric deck oven which has a tested minimum heavy load cooking efficiency of 60%, and has an idle energy rate of no greater than 1.3 kW.[2]

Deck Oven Measure Case:

	Minimum Cooking Efficiency	Maximum Idle Energy Rate
Electric Deck Oven	60%	1.3 kW

DEFINITION OF BASELINE EQUIPMENT

The base case electric deck oven is described as an electric deck oven with a tested average cooking efficiency which does not meet the measure case criteria.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected effective useful life of the measure electric deck oven is estimated to be 12 years.[374] [375]

DEEMED MEASURE COST

The incremental capital cost for this measure is $1022 normalized per deck after considering common discounts.[376]

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 0.900[377]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS[378]

ΔAnnual_kWh = $(\Delta DailyIdleEnergy + \Delta DailyPreheatEnergy + \Delta DailyCookingEnergy) * Days$

ΔDailyIdleEnergy = $(IdleRate_{base} - IdleRate_{measure}) * (Hours - Food / PC - Preheats * PreheatTime / 60)$

ΔDailyPreheatEnergy = $Preheats * (PreheatEnergy_{base} - PreheatEnergy_{measure})$

ΔDailyCookingEnergy = $(Food * 0.0732 / CookingEff_{base}) - (Food * 0.0732 / CookingEff_{measure})$

Where:[379] [380]

Days = Annual days of operation

= Actual, or if unknown, use 365 days per year

Hours = Average daily hours of operation

= Actual, or if unknown, use 12 hours

$IdleRate_{base}$ = Idle energy rate of baseline electric deck oven

= 1.90 kW

$IdleRate_{measure}$ = Idle energy rate of measure electric deck oven

= Actual, or if unknown, use 1.30 kW

Food = Average pounds of food cooked per day

= Actual, or if unknown, use 200 lb/day

PC = Production Capacity of the electric deck oven

= 60 lb/h

Preheats = Average number of times the unit is preheated in any given day

= Actual, or if unknown, use 1

PreheatTime = Estimated time that the unit spends in the preheat mode

= 30 min

60 = Minutes to hours conversion factor

$PreheatEnergy_{base}$ = Energy use of the baseline electric deck oven during a preheat

= Actual, or if unknown, use 6.50 kWh

$PreheatEnergy_{measure}$ = Energy use of the measure electric deck oven during a preheat

= Actual, or if unknown, use 3.00 kWh

0.0732 = ASTM energy to food ratio; the energy absorbed by the food during cooking in kWh/lb

[378] American Society for Testing and Materials (ASTM). 2010. *ASTM F1965-99, Standard Test Method for the Performance of Deck Ovens.* West Conshohocken (PA): ASTM International.

[379] Food Service Technology Center (FSTC). (n.d.) Proprietary database

[380] Southern California Edison (SCE). 2018. "SCE17CC012.1 A2 - Cost & Savings Calculations.xlsm."

$CookingEff_{base}$ = Heavy load cooking energy efficiency of the baseline electric deck oven

= Actual, or if unknown, use 40%

$CookingEff_{measure}$ = Heavy load cooking energy efficiency of the measure electric deck oven

= Actual, or if unknown, use 60%

For example, for a measure case electric deck oven compared to the baseline electric deck oven using the default values from above would save:

ΔAnnual_kWh $= (\Delta DailyIdleEnergy + \Delta DailyPreheatEnergy + \Delta DailyCookingEnergy) * Days$

Where:

ΔDailyIdleEnergy = (1.9 – 1.3) * (12 – 200 / 60 – 1 * 30 / 60)

= 4.9 kWh

ΔDailyPreheatEnergy = 1 * (6.5 – 3.0)

= 3.5 kWh

ΔDailyCookingEnergy = (200 * 0.0732 / 0.40) – (200 * 0.0732 / 0.60)

= 12.2 kWh

ΔAnnual_kWh = (4.9 + 3.5 + 12.2) * 365

= 7,519.0 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW $= \Delta kWh / (Hours * Days) * CF$

Where:[381]

ΔkWh = Annual kWh savings from measure as calculated above

Hours = Average daily hours of operation

= Actual, or if unknown, use 12 hours

Days = Annual days of operation

= Actual, or if unknown, use 365 days per year

CF = Summer Peak Coincidence Factor for measure

= 0.900

[381] Itron, Inc. 2005. *2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report*. Prepared for Southern California Edison.

For example, for a measure case electric deck oven compared to the baseline electric deck oven using the default values from above would save:

ΔkW = $\Delta kWh \ / \ (Hours \ * \ Days) \ * \ CF$

Where:

ΔkWh = Annual kWh savings from measure as calculated from the previous example using default values

= 7,519.0 kWh

ΔkW = 7,519.0 / (12 * 365) * 0.900

= 1.545 kW

4.2.24 Gas and Electric Pressure Fryers

DESCRIPTION

This measure applies to electric or natural gas fired pressure fryers installed in a commercial kitchen which have a minimum cooking efficiency and maximum idle rate standards based on lab testing following ASTM F1964-21 Standard Test Method for Performance of Pressure Fryers.[382]

This measure was developed to be applicable to the following program types: TOS and NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The measure case is a new pressure fryer which meets the minimum cooking efficiency and maximum idle energy rate standards as tested following ASTM F1964-21.[3] These standards are comparable to the ENERGY STAR standards for large open deep fat fryers[383] and are based on the efficiency levels of the most efficient pressure fryers tested for each fuel type.

Pressure Fryer Measure Case

	Minimum Cooking Efficiency	Maximum Idle Rate
Electric Pressure Fryer	83%	0.7 kW
Gas Pressure Fryer	40%	9,000 Btu/h

DEFINITION OF BASELINE EQUIPMENT

The base case pressure fryer is described as a pressure fryer with a tested average cooking efficiency and idle energy rate which do not meet the measure case criteria.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected lifetime of the measure equipment is assumed to be 12 years for electric pressure fryers and 11 years for gas fired pressure fryers.[384] [385]

DEEMED MEASURE COST

The incremental capital cost for this measure is $6,394 for electric pressure fryers and $4054 for gas pressure fryers.[386]

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS & FOSSIL FUEL SAVINGS

Non-Fuel Switch Measures:

The algorithms below apply to electric fryers only.

ΔAnnual_kWh = $(\Delta DailyIdleEnergy + \Delta DailyActiveEnergy) * Days / 1{,}000$

ΔDailyIdleEnergy = $(IdleRate_{base} - IdleRate_{measure}) * TimeIdle$

ΔDailyActiveEnergy = $(TimeActive * InputRate_{base}) - [(TimeActive * InputRate_{measure}) * CookTimeSaved]$

The algorithms below apply to gas fryers only.

ΔAnnual_Therms = $(\Delta DailyIdleEnergy + \Delta DailyActiveEnergy) * Days / 100{,}000$

ΔDailyIdleEnergy = $(IdleRate_{base} - IdleRate_{measure}) * TimeIdle$

ΔDailyActiveEnergy =$(TimeActive * InputRate_{base}) - [(TimeActive * InputRate_{measure}) * CookTimeSaved]$

Fuel-Switch / Electrification Measures:

Fuel switch / electrification measures must product positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. The following algorithm can be used to determine eligibility:

SiteEnergySavings (MMBTUs) = $[GasConsumptionReplaced] - [ElectricalConsumptionAdded]$

=$[DailyIdleEnergy_{GasBase} + DailyActiveEnergy_{GasBase}] - [DailyIdleEnergy_{ElectricMeasure} + DailyActiveEnergy_{ElectricMeasure}]$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claims are dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remain the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:[387]

Days = Annual days of operation

= Actual, or if unknown, use 326[388] days per year

1,000 = Wh to kWh conversion factor

[387] UNPUBLISHED Frontier Energy, Inc. "Pressure_Fryer_Workpaper_Calculations_Draft_R2 2023-07-31.xlsx". May 2023.
[388] Fisher-Nickel, Inc. *Characterizing the Energy Efficiency Potential of Gas-Fired Commercial Foodservice Equipment.* Prepared for the California Energy Commission (CEC). CEC-500-2014-095. October 2014.

$IdleRate_{base}$ = Idle energy rate of baseline pressure fryer

= Actual, or if unknown, use:

Equipment Type	IdleRate
Electric	1.0 kW
Gas	10,500 Btu/h

$IdleRate_{measure}$ = Idle energy rate of measure pressure fryer

= Actual, or if unknown, use:

Equipment Type	IdleRate
Electric	0.7 kW
Gas	9,000 Btu/h

TimeIdle = Daily operating time that the electric pressure fryer is in idle state

= Actual, of if unknown, use 9.50 hours

TimeActive = Daily operating time the electric pressure fryer is in an active state (preheat or cook)

= Actual, or if unknown, use 2.64 hours

$InputRate_{base}$ = Preheat energy rate of the baseline pressure fryer

= Actual, or if unknown, use:

Equipment Type	Input Rate
Electric	16 kW
Gas	75,000 Btu/hr

$InputRate_{measure}$ = Preheat energy rate of the measure pressure fryer

= Actual, or if unknown, use:

Equipment Type	Input Rate
Electric	17 kW
Gas	60,000 Btu/hr

CookTimeSaved = Percentage of time saved cooking by the measure electric pressure fryer

= Can be calculated using actual values using the following algorithm:

$CookTime_{measure}$ / $CookTime_{baseline}$

or

if unknown, use 0.88 for an electric pressure fryer or 0.83 for a gas pressure fryer

For fuel-switch / electrification measure use 0.88

Where:

$CookTime_{measure}$ = The amount of time to cook one load of the food product (min)

= Actual, or if unknown, use:

Equipment Type	CookTime (minutes)
Electric	13.5
Gas	12.7

$CookTime_{baseline}$ = The amount of time to cook on load of the food product (min)

= Actual, or if unknown, use:

Equipment Type	CookTime (minutes)
Electric	15.2
Gas	15.3

100,000 = Btu to therms conversion factor

For example, for a measure case electric pressure fryer replacing a baseline natural gas pressure fryer using the default values from the measure case in Electric Energy Savings above and the base case in Natural Gas Savings below would save:

SiteEnergySavings (MMBTUs) = $[GasConsumptionReplaced] - [ElectricalConsumptionAdded]$
$= [(DailyIdleEnergy_{GasBase} + DailyActiveEnergy_{GasBase}) * Days / 1{,}000{,}000] - [(DailyIdleEnergy_{ElectricMeasure} + DailyActiveEnergy_{ElectricMeasure}) * Days * 3{,}412 / 1{,}000{,}000]$

$DailyIdleEnergy_{GasBase}$ = $IdleRate_{Gasbase} * TimeIdle$
= 10,500 * 9.50
= 99,750 btu

$DailyActiveEnergy_{GasBase}$ = $TimeActive * InputRate_{GasBase}$
= 2.64 * 75,000
= 198,000 btu

$DailyIdleEnergy_{ElectricMeasure}$ = $IdleRate_{ElectricMeasure} * TimeIdle$
= 0.700 * 9.50
= 6.65 kWh

$DailyActiveEnergy_{ElectricMeasure}$ = $TimeActive * InputRate_{ElectricMeasure} * CookTimeSaved$
= 2.64 * 17 * 0.88
= 39.49 kWh

SiteEnergySavings (MMBTUs) = [(99,750 + 198,000) * 326 / 1,000,000] – [(6.65 + 39.49) * 326 * 3,412 / 1,000,000]
= 45.9 MMBTU

If supported by an electric utility = $SiteEnergySavings * 1{,}000{,}000 / 3{,}412$
= 45.9 * 1,000,000 / 3,412
= 13,440 kWh

For example, for a measure case electric pressures compared to the baseline gas pressure fryer using the default values from above would save:

ΔAnnual_Therms = $(\Delta DailyIdleEnergy + \Delta DailyActiveEnergy) * Days / 100{,}000$

Where:

ΔDailyIdleEnergy = (10,500 – 9,000) * 9.50

= 14,250 Btu

ΔDailyActiveEnergy = (2.64 * 75,000) – ((2.64 * 60,000) * 0.83)

= 66,528 Btu

ΔAnnual_Therms = (14,250 + 66,528) * 326 / 100,000

= 263 Therms

For example, for a measure case electric pressure fryer compared to the baseline electric pressure fryer using the default values from above would save:

ΔAnnual_kWh = $(\Delta DailyIdleEnergy + \Delta DailyActiveEnergy) * Days$

Where:

ΔDailyIdleEnergy = (1.0 – 0.7) * 9.50

= 2.850 kWh

ΔDailyActiveEnergy = (2.64 * 16) – ((2.64 * 17) * 0.88)

= 2.746 kWh

ΔAnnual_kWh = (2.850 + 2.746) * 326

= 1,824 kWh

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = $[Gas\ Cooking\ Consumption\ Replaced]$

=$[((IdleRate_{base} * TimeIdle) + ((TimeActive * InputRate_{base}) * CookTimeSaved)) * Days / 100{,}000]$

ΔkWh = $[Electric\ Cooking\ Consumption\ Added]$

=$- [((IdleRate_{measure} * TimeIdle) + ((TimeActive * InputRate_{measure}) * CookTimeSaved)) * Days / 1{,}000]$

REVIEW DEADLINE: 1/1/2028

4.2.25 Efficient Cooktops

DESCRIPTION

This measure applies to new induction or natural gas cooktops installed in a commercial kitchen which have minimum heavy load cooking efficiency and maximum idle rate standards as defined below, based on lab testing following ASTM F1521-22 Standard Test Methods for Performance of Range Tops.[389]

This measure was developed to be applicable to the following program types: TOS and NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The measure case is described as a new cooktop which has a tested minimum cooking efficiency defined below, as determined by lab testing following ASTM F1521. Where applicable, values align with ENERGY STAR[390] program criteria.[391]

Induction Cooktop Measure Case:

	Minimum Cooking Efficiency
Induction Cooktop	80%
Gas Cooktop	43%

DEFINITION OF BASELINE EQUIPMENT

The base case cooktop is described as a new natural gas or electric induction cooktop with a tested average cooking efficiency which does not meet the measure case criteria. This measure has not been designed to support electric resistance-based burner designs.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected effective useful life of the measure cooktop is estimated to be 12 years.[392] [393]

DEEMED MEASURE COST

The incremental capital cost for this measure is defined below, normalized per burner:[394]

Fuel Source	Incremental Measure Cost
Electric	$560
Gas	$127
Fuel-Switch	$950

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

[390] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[391] ENERGY STAR Commercial Electric Cooktops, version 1.0, drafted January 12, 2023

[392] Itron, Inc. 2005. *2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report*. Prepared for Southern California Edison.

[393] California Public Utilities Commission (CPUC), Energy Division. 2003. *Energy Efficiency Policy Manual v 2.0.*

[394] Frontier Energy, Inc. 2023. "Cooktop_Supporting_Data_R2 2023-07-30.xlsx".

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 0.900[4]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS AND FOSSIL FUEL SAVINGS[395]

Non Fuel-Switch Measures:

The algorithms below apply to electric cooktops only.

ΔAnnual_kWh = $(\Delta DailyCookingEnergy) * Days$

ΔDailyCookingEnergy = $(Food * (130 / 3{,}412) / CookingEff_{base}) - (Food * (130 / 3{,}412) / CookingEff_{measure})$

The algorithms below apply to gas cooktops only.

ΔAnnual_Therms = $(\Delta DailyCookingEnergy + \Delta DailyPilotEnergy) * Days / 100{,}000$

ΔDailyCookingEnergy =$(Food * 130 / CookingEff_{base}) - (Food * 130 / CookingEff_{measure})$

ΔDailyPilotEnergy =$(PilotRate_{base} * (24 - Food / ProdCap_{base})) - (PilotRate_{measure} * (24 - Food / ProdCap_{measure}))$

Fuel-Switch / Electrification Measures:

Fuel switch / electrification measures must product positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. The following algorithm can be used to determine eligibility:

SiteEnergySavings (MMBTUs) = $[GasConsumptionReplaced] - [ElectricalConsumptionAdded]$

=$[DailyCookingEnergy_{GasBase} + DailyPilotEnergy_{GasBase}] - [DailyCookingEnergy_{ElectricMeasure}]$

It should be noted that the Food variable shall be similar from one unit to the other when fuel-switching.

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claims are dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remain the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:[7]

Days = Annual days of operation

[395] Frontier Energy, Inc. 2023. "Cooktop_Supporting_Data_R2 2023-07-30.xlsx"

= Actual, or if unknown, use 326 days per year

Food = Average pounds of food cooked per day

= Actual, or if unknown, use 108 lb/day for an electric cooktop or 143lb/day for a gas cooktop. For fuel switching scenarios, use same Food assumption for both baseline and efficient.

130 = ASTM energy to food ratio; the energy absorbed by the food during cooking in Btu/lb

3412 = Btu to kWh conversion factor

$CookingEff_{base}$ = Heavy load cooking energy efficiency of the baseline cooktop

= Actual, or if unknown, use:

Equipment Type	Cooking Efficiency
Electric	75%
Gas	34%

$CookingEff_{measure}$ = Heavy load cooking energy efficiency of the measure induction cooktop

= Actual, or if unknown, use:

Equipment Type	Cooking Efficiency
Electric	84%
Gas	47%

100,000 = Btu to therms conversion factor

$PilotRate_{base}$ = Input energy rate of pilot found on baseline gas cooktop

= Actual, or if unknown, use 500 Btu/h

$PilotRate_{measure}$ = Input energy rate of pilot found on measure gas cooktop

= Actual, or if unknown, use 460 Btu/h

24 = Hours in a day

$ProdCap_{base}$ = Production Capacity of baseline gas cooktop

= Actual, or if unknown, use 78 lb/h

$ProdCap_{measure}$ = Production Capacity of measure gas cooktop

= Actual, or if unknown, use 66 lb/h

For example, for a measure case induction cooktop compared to the baseline induction cooktop using the default values from above would save:

ΔAnnual_kWh = $\Delta DailyCookingEnergy * Days$

Where:

ΔDailyCookingEnergy = (108 * (130 / 3412) / 0.75) – (108 * (130 / 3412) / 0.84)

= 0.588 kWh

ΔAnnual_kWh = 0.588 * 326

= 191.628 kWh

For example, for a measure case gas cooktop compared to the baseline gas cooktop using the default values from above would save:

ΔAnnual_Therms = $(\Delta DailyCookingEnergy + \Delta DailyPilotEnergy) * Days / 100{,}000$

Where:

ΔDailyCookingEnergy = (143 * 130 / 0.34) – (143 * 130 / 0.47)

= 15,123 Btu

ΔDailyPilotEnergy = 500 * (24 – 143 / 78) – 460 * (24 – 143 / 66)

= 1040 Btu

ΔAnnual_Therms = (15,123 + 1040) * 326 / 100,000

= 52.69 Therms

For example, for a measure case electric induction cooktop replacing a baseline natural gas cooktop using the default values from the measure case in Electric Energy Savings above and the base case in Natural Gas Savings below would save:

SiteEnergySavings (MMBTUs) = $[GasConsumptionReplaced] - [ElectricalConsumptionAdded]$
$=[(DailyCookingEnergy_{GasBase} + DailyPilotEnergy_{GasBase}) * Days / 1{,}000{,}000 - [DailyCookingEnergy_{ElectricMeasure} * Days * 3{,}412 / 1{,}000{,}000]$

DailyCookingEnergy$_{GasBase}$ = $Food * 130 / CookingEff_{GasBase}$
= 143 * 130 / 0.34
= 54,677 btu

DailyPilotEnergy$_{GasBase}$ = $PilotRate_{GasBase} * (24 - Food / ProdCap_{GasBase})$
= 500 * (24 – 143 / 78)
= 11,083 btu

DailyCookingEnergy$_{ElectricMeasure}$ = $Food * 130 / 3{,}412 / CookingEff_{ElectricMeasure}$
= 143 * 130 / 3,412 / 0.84
= 6.49 kWh

SiteEnergySavings (MMBTUs) = $[(54{,}677 + 11{,}083) * 326 / 1{,}000{,}000] - [6.49 * 326 * 3{,}412 / 1{,}000{,}000]$
= 14.2 MMBTU

If supported by an electric utility = $SiteEnergySavings * 1{,}000{,}000 / 3{,}412$
= 14.2 * 1,000,000 / 3,412
= 4,169 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = $\Delta kWh / (Hours * Days) * CF$

Where:[396]

ΔkWh = Annual kWh savings from measure as calculated above

Hours = Average daily hours of operation
= Actual, or if unknown, use 6 hours

Days = Annual days of operation
= Actual, or if unknown, use 326 days per year

CF = Summer Peak Coincidence Factor for measure
= 0.900

[396] Itron, Inc. 2005. *2004-2005 Database for Energy Efficiency Resources (DEER) Update Study - Final Report*. Prepared for Southern California Edison.

For example, for a measure case induction cooktop compared to the baseline induction cooktop using the default values from above would save:

ΔkW = $\Delta kWh \ / \ (Hours * Days) * CF$

Where:

ΔkWh = Annual kWh savings from measure as calculated from the previous example using default values

= 191.628 kWh

ΔkW = 191.682 / (6 * 326) * 0.900

= 0.088 kW

ΔDailyCookingEnergy = (93 * (130 / 3412.14) / 0.75) – (93 * (130 / 3412.14) / 0.84)

= 0.506176 kWh

ΔAnnual_kWh = 0.506176 * 326

= 119.458 kWh

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = $[Gas\ Cooking\ Consumption\ Replaced]$

= $[((PilotRate_{base} * (24 - Food \ / \ ProdCap_{base})) + (Food * 130 \ / \ CookingEffe_{Gasbas})) * Days \ / \ 100{,}000]$

ΔkWh = $[Electric\ Cooking\ Consumption\ Added]$

= $-[(Food * (130 \ / \ 3{,}412) \ / \ CookingEff_{Elecmeasure}) * Days]$

MEASURE CODE: CI-FSE-INDC-V02-260101

REVIEW DEADLINE: 1/1/2028

4.3. Hot Water End Use

4.3.1 Water Heater

DESCRIPTION

This measure is for upgrading from minimum code to a high efficiency water heater. Storage water heaters are used to supply hot water for a variety of commercial building types. Storage capacities vary greatly depending on the application. Large consumers of hot water include (but not limited to) industries, hotels/motels and restaurants.

Tankless water heaters function similar to standard hot water heaters except they do not have a storage tank. When there is a call for hot water, the water is heated instantaneously as it passes through the heating element and then proceeds to the user or appliance calling for hot water. Tankless water heaters achieve savings by eliminating the standby losses that occur in stand-alone or tank-type water heaters and by being more efficient than the baseline storage hot water heater.

Heat pump water heaters use electricity to move heat from one place to another instead of generating heat directly and can allow for additional energy savings. Savings are presented dependent on the heating system installed in the home due to the impact of the heat pump water heater on the heating loads.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The minimum specifications of the high efficiency equipment should be defined by the programs.

DEFINITION OF BASELINE EQUIPMENT

Time of Sale: The baseline condition is assumed to be a new standard water heater of same type as the existing unit being replaced, meeting the Federal Standard for ≤75,000 Btuh units and IECC 2021 for all others. If existing type is unknown, assume same water heater type as the efficient unit.

For Residential-sized >55 gallon HPWH tanks, the baseline should assume the same capacity and use the appropriate standard listed below, unless it can be confirmed that the existing tank being replaced was <55 gallon (and the larger tank is only being used to achieve greater efficiency of the heat pump cycle and prevent the unit from going in to resistance mode), in which case the existing unit capacity and the <55 gallon algorithms should be used.

New Construction: The baseline condition is a new standard water heater of the same type as the efficient, meeting the IECC code level in place at the time the building permit was issued. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints. Note, IECC 2021 became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code.

Note the same draw pattern (very small, low, medium and high draw) should be used for both baseline and efficient units. Definitions of draw pattern are provided below.

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[397]
Residential Gas Storage Water Heaters ≤75,000 Btu/h	≤55 gallon tanks	Very small	UEF = 0.3456 – (0.0020 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5982 – (0.0019 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6483 – (0.0017 * Rated Storage Volume in Gallons)
		High	UEF = 0.6920 – (0.0013 * Rated Storage Volume in Gallons)
		Very small	UEF = 0.6470 – (0.0006 * Rated Storage Volume in Gallons)

[397] All Residential sized Federal Standards are from DOE Standard 10 CFR 430, Residential-Duty and Commercial Federal Standard are from DOE Standard 10 CFR 431.

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[397]
	>55 gallon and ≤100 gallon tanks	Low	UEF = 0.7689 – (0.0005 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.7897 – (0.0004 * Rated Storage Volume in Gallons)
		High	UEF = 0.8072 – (0.0003 * Rated Storage Volume in Gallons)
Residential-duty Commercial High Capacity Storage Gas-Fired Storage Water Heaters > 75,000 Btu/h	≤120 gallon tanks	Very small	UEF = 0.2674 – (0.0009 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5362 – (0.0012 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6002 – (0.0011 * Rated Storage Volume in Gallons)
		High	UEF = 0.6597 – (0.0009 * Rated Storage Volume in Gallons)
Commercial Gas Storage Water Heaters >75,000 Btu/h and ≤155,000 Btu/h	>120 gallon tanks	All	80% $E_{thermal}$, Standby Losses = (Q /800 + 110√Rated Storage Volume in Gallons)
Commercial Gas Storage Water Heaters >155,000 Btu/h			
Residential Gas Instantaneous Water Heaters ≤ 200,000 Btu/h	≤2 gal	Very low	UEF = 0.80
		All other	UEF = 0.81
Commercial Gas Instantaneous Water Heaters > 200,000 Btu/h	<10 gal	All	80% $E_{thermal}$
	≥10 gal	All	80% $E_{thermal}$
Residential Electric Storage Water Heaters ≤ 75,000 Btu/h	≤55 gallon tanks	Very small	UEF = 0.8808 – (0.0008 * Rated Storage Volume in Gallons)
		Low	UEF = 0.9254 – (0.0003 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.9307 – (0.0002 * Rated Storage Volume in Gallons)
		High	UEF = 0.9349 – (0.0001 * Rated Storage Volume in Gallons)
	>55 gallon and ≤120 gallon tanks [398]	Very small	UEF = 1.9236 – (0.0011 * Rated Storage Volume in Gallons)
		Low	UEF = 2.0440 – (0.0011 * Rated Storage Volume in Gallons)
		Medium	UEF = 2.1171 – (0.0011 * Rated Storage Volume in Gallons)
		High	UEF = 2.2418 – (0.0011 * Rated Storage Volume in Gallons)
Residential Electric Instantaneous Water Heaters	≤12kW and ≤2 gal	All other	UEF = 0.91
		High	UEF = 0.92
Residential-duty Commercial Electric Instantaneous Water Heaters	> 12kW and ≤58.6 kW and ≤2 gal	All	UEF = 0.80

Residential-duty Commercial Water Heaters meet the following criteria:

- Is not designed to provide outlet hot water at temperatures greater than 180 °F; and
- If electric, must use a single-phase external power supply; and
- Gas-fired Storage Water Heater with a rated input no greater than 105 kBtu/h and a DOE Rated Storage volume no greater than 120 gallons.
- Electric Instantaneous with a rated input no greater than 58.6 kW and a DOE Rated Storage volume no greater than 2 gallons.

Draw patterns are based on first hour rating (gallons) for storage tanks and maximum flow (GPM) for instantaneous as shown below:[399]

[398] It is assumed that tanks <75,000Btu/h and >55 gallons will not be eligible measures due to the high baseline.

[399] Definitions provided in 10 CFR 430, Subpart B, Appendix E, Section 5.4.1.

Storage Water Heater Draw Pattern	
Draw Pattern	**First Hour Rating (gallons)**
Very Small	≥ 0 and < 18
Low	≥ 18 and < 51
Medium	≥ 51 and < 75
High	≥ 75

Instantaneous Water Heater Draw Pattern	
Draw Pattern	**Max GPM**
Very Small	≥ 0 and < 1.7
Low	≥ 1.7 and < 2.8
Medium	≥ 2.8 and < 4
High	≥ 4

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years for storage[400] and heat pump units[401], 5 years for electric tankless,[402] and 20 years for gas tankless.[403]

DEEMED MEASURE COST

The full install cost and incremental cost assumptions are provided below. Actual costs should be used where available:

Gas storage water heaters:[404]

Equipment Type	Category	Install Cost	Incremental Cost
Gas Storage Water Heaters ≤ 75,000 Btu/h, ≤55 Gallons	Baseline	$616	N/A
	Efficient	$1,055	$440
Gas Storage Water Heaters > 75,000 Btu/h	0.80 Et	$4,886	N/A
	0.83 Et	$5,106	$220
	0.84 Et	$5,299	$413
	0.85 Et	$5,415	$529
	0.86 Et	$5,532	$646
	0.87 Et	$5,648	$762
	0.88 Et	$5,765	$879
	0.89 Et	$5,882	$996
	0.90 Et	$6,021	$1,135

For electric water heaters, the incremental capital cost for this measure is assumed to be:[405]

[400] DEER 08, EUL_Summary_10-1-08.xls.
[401] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.
[402] Ohio Technical Reference Manual 8/2/2010 referencing CenterPoint Energy-Triennial CIP/DSM Plan 2010-2012 Report; Additional reference stating >20 years is soured from the US DOE Energy Savers for Tankless or Demand-Type Water Heaters.
[403] Ibid.
[404] Cost information is based upon data from "2010-2012 WA017 Ex Ante Measure Cost Study Draft Report", Itron, February 28, 2014. See "NR HW Heater_WA017_MCS Results Matrix - Volume I.xls" for more information.
[405] Act on Energy Commercial Technical Reference Manual, Table 9.6.1-4

Tank Size	Incremental Cost
50 gallons	$1050
80 gallons	$1050
100 gallons	$1950

The incremental capital cost for an electric tankless heater this measure is assumed to be:[406]

Output (gpm) at delta T 70	Incremental Cost
5	$1050
10	$1050
15	$1950

The incremental capital cost for a gas fired tankless heater is assumed to be[407]:

Output (gpm) at delta T 70	Incremental Cost
5.0	$1,500
10.0	$1,500
15.0	$2,400

For a heat pump water heater, the incremental installation cost (including labor) should be used. Defaults are provided below.[408] Actual efficient costs can also be used although care should be taken as installation costs can vary For a heat pump water heater, the incremental installation cost (including labor) should be used. Defaults are provided below.[409] Actual efficient costs can also be used although care should be taken as installation costs can vary significantly due to complexities of a particular site.

Capacity	Efficiency Range	Baseline Installed Cost	Efficient Installed Cost	Incremental Installed Cost
≤55 gallons	<2.6 UEF	$1,032	$2,062	$1,030
	≥2.6 UEF	$1,032	$2,231	$1,199
>55 gallons	<2.6 UEF	$1,319	$2,432	$1,113
	≥2.6 UEF	$1,319	$3,116	$1,797

LOADSHAPE

For electric hot water heaters, use Loadshape C02 - Commercial Electric DHW.

[406] Act on Energy Technical Reference Manual, Table 9.6.2-3
[407] Act on Energy Commercial Technical Reference Manual, Table 9.6.3-4. Please see file 'Ameren C and I TRM.pdf' for further details.
[408] Costs for <2.6 UEF are based upon averages from the NEEP Phase 3 Incremental Cost Study. The assumption for higher efficiency tanks is based upon averaged from NEEP Phase 4 Incremental Cost Study. See 'HPWH Cost Estimation.xls' for more information.
[409] Costs for <2.6 UEF are based upon averages from the NEEP Phase 3 Incremental Cost Study. The assumption for higher efficiency tanks is based upon averaged from NEEP Phase 4 Incremental Cost Study. See 'HPWH Cost Estimation.xls' for more information.

COINCIDENCE FACTOR

The coincidence factor is assumed to be 0.925.[410]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS

Non-Fuel Switch Measures:

Electric energy savings are calculated for electric water heaters per the equations given below.

Electric units ≤12 kW:

$$\Delta kWh = \frac{(T_{out} - T_{in}) \ * \ HotWaterUse_{Gallon} * \gamma Water * 1 * \left(\frac{1}{UEF_{elecbase}} - \frac{1}{UEF_{Eff}}\right)}{3412}$$

$$+HPWHWasteHeat_{cool} - \ HPWHWasteHeat_{heat}$$

Electric units > 12kW:

$$\Delta kWh = \frac{\left((T_{out} - T_{air}) * V * \gamma Water * 1 * \left(\frac{SL_{elecbase} - \ SL_{eff}}{100}\right)\right) * 8766}{3412}$$

Natural gas energy savings are calculated for natural gas storage water heaters per the equations given below.

$$\Delta Therms = \frac{(T_{out} - T_{in}) \ * \ HotWaterUse_{Gallon} * \gamma Water * 1 * \left(\frac{1}{UEF_{gasbase}} - \frac{1}{UEF_{Eff}}\right)}{100{,}000} - \ HPWHWasteHeat_{GasHeat}$$

Additional Standby Loss Savings:

Gas Storage Water Heaters >75,000 Btu/h can claim additional savings due to lower standby losses.

$$\Delta Therms_{Standby} = \frac{(SL_{gasbase} - SL_{eff}) * 8766}{100{,}000}$$

Fuel Switch/Electrification Measures:

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

Electric units ≤12 kW:

SiteEnergySavings (MMBTUs) = [GasConsumptionReplaced] – [ElectricConsumptionAdded]

[410] Coincidence factor based on Average W in peak period/Max W from Itron eShape data for Missouri, calibrated to Illinois loads.

$$= \left[\frac{(T_{out}-T_{in}) * HotWaterUse_{Gallon}*\gamma Water*1*\left(\frac{1}{UEF_{gasbase}}\right)}{1{,}000{,}000}\right] - \left[\frac{(T_{out}-T_{in}) * HotWaterUse_{Gallon}*\gamma Water*1*\left(\frac{1}{UEF_{Eff}}\right)}{1{,}000{,}000} + HPWHWasteHeat_{cool} - HPWHWasteHeat_{heat}\right]$$

Electric units > 12kW and gas units >75,000 Btu/h:

SiteEnergySavings (MMBTUs) = [GasConsumptionReplaced] – [ElectricConsumptionAdded] + (HPWHWasteHeat$_{cool}$ * 0.003412) – (HPWHWasteHeat$_{heat}$ * ConversionToMMBtu)

$$[\text{GasConsumptionReplaced}] = \left[\frac{(T_{out}-T_{in}) * HotWaterUse_{Gallon}*\gamma Water*1*\left(\frac{1}{UEF_{gasbase}}\right)}{1{,}000{,}000} + \frac{(SL_{gasbase}*8766)}{1{,}000{,}000}\right]$$

$$[\text{ElectricConsumptionAdded}] = \left[\frac{(T_{out}-T_{in}) * HotWaterUse_{Gallon}*\gamma Water*1*\left(\frac{1}{UEF_{Eff}}\right)}{1{,}000{,}000} + \frac{\left((T_{out}-T_{air})*V*\gamma Water*1*\left(\frac{SL_{eff}}{100}\right)\right)*8766}{1{,}000{,}000}\right]$$

$$\text{HPWHWasteHeat}_{cool} = \left[\frac{\left((T_{OUT}-T_{IN})* HotWaterUse_{Gallon}*\gamma Water*1*\left(1-\frac{1}{UEF_{Eff}}\right)\right)*LF*25\%*LM}{COP_{COOL}*3412}\right]*Cool$$

$$\text{HPWHWasteHeat}_{heat} =$$

$$\text{If Electric Heat} = \left[\frac{\left((T_{OUT}-T_{IN})* HotWaterUse_{Gallon}*\gamma Water*1*\left(1-\frac{1}{UEF_{Eff}}\right)\right)*\text{LF}*35\%}{\text{COP}_{\text{HEAT}}*3412}\right]*\text{ElectricHeat}$$

$$\text{If Gas Heat} = \left[\frac{\left((T_{OUT}-T_{IN})* HotWaterUse_{Gallon}*\gamma Water*1*\left(1-\frac{1}{UEF_{Eff}}\right)\right)*\text{LF}*35\%}{100{,}000*\eta Heat}\right]*(1-\text{ElectricHeat})$$

ConversionToMMBtu =

If Electric Heat = 0.003412 kWh/MMBtu

If Gas Heat = 0.1 Therms/MMBtu

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure Supported By:	Electric Utility Claims (kWh):	Gas Utility Claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:

T_{OUT} = Tank temperature

= 125°F

T_{IN} = Incoming water temperature from well or municiple system

= 50.7°F [411]

$HotWaterUse_{Gallon}$ = Estimated annual hot water consumption (gallons)

= Actual if possible to provide reasonable custom estimate. If not, two methodologies are provided to develop an estimate:

1. Consumption per usable storage tank capacity

   = Capacity * Consumption/cap

   Where:

   Capacity = Usable capacity of hot water storage tank in gallons

   = Actual

   Consumption/cap = Estimate of consumption per gallon of usable tank capacity, based on building type:[412]

Building Type[413]	Consumption/Cap
Convenience	528
Education	568
Grocery	528
Health	788
Large Office	511
Large Retail	528
Lodging	715
Other Commercial	341

[411] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[412] Methodology based on Cadmus analysis. Annual hot water usage in gallons based on CBECS (2012) and RECS (2009) consumption data of East North Central (removed outliers of 1,000 kBtuh or less) to calculate hot water usage. Annual hot water gallons per tank size gallons based on the tank sizing methodology found in ASHRAE 2011 HVAC Applications. Chapter 50 Service Water Heating. Demand assumptions (gallons per day) for each building type based on ASHRAE Chapter 50 and to LBNL White Paper. LBL-37398 Technology Data Characterizing Water Heating in Commercial Buildings: Application to End Use Forecasting. Assumes hot water heater efficiency of 80%.

[413] According to CBECS 2012 "Lodging" buildings include Dormitories, Hotels, Motel or Inns and other Lodging and "Nursing" buildings include Assisted Living and Nursing Homes.

Building Type[413]	Consumption/Cap
Restaurant	622
Small Office	511
Small Retail	528
Warehouse	341
Nursing	672
Multi-Family	894
Unknown	555[414]

2. Consumption per unit area by building type
= (Area/1000) * Consumption/1,000 sq.ft.

Where:

Area = Area in sq.ft that is served by DHW boiler

= Actual

Consumption/1,000 sq.ft. = Estimate of DHW consumption per 1,000 sq.ft. based on building type:[415]

Building Type[416]	Consumption/1,000 sq.ft.
Convenience	4,594
Education	7,285
Grocery	697
Health	24,540
Large Office	1,818
Large Retail	1,354
Lodging	29,548
Other Commercial	3,941
Restaurant	44,439
Small Office	1,540
Small Retail	6,111
Warehouse	1,239
Nursing	30,503
Multi-Family	15,434

γWater = Specific weight capacity of water (lb/gal)

= 8.33 lbs/gal

1 = Specific heat of water (Btu/lb.°F)

$UEF_{elecbase}$ = Rated efficiency of baseline water heater expressed as Uniform Energy Factor (UEF);

[414] From a historical average of all Ameren Illinois commercial & industrial water heater applications from 2013-2022

[415] Methodology based on Cadmus analysis. Annual hot water usage in gallons based on CBECS (2012) and RECS (2009) consumption data of East North Central (removed outliers of 1,000 kBtuh or less) to calculate hot water usage. Annual hot water gallons per tank size gallons based on the tank sizing methodology found in ASHRAE 2011 HVAC Applications. Chapter 50 Service Water Heating. Demand assumptions (gallons per day) for each building type based on ASHRAE Chapter 50 and to LBNL White Paper. LBL-37398 Technology Data Characterizing Water Heating in Commercial Buildings: Application to End Use Forecasting. Assumes hot water heater efficiency of 80%.

[416] According to CBECS 2012 “Lodging” buildings include Dormitories, Hotels, Motel or Inns and other Lodging and “Nursing” buildings include Assisted Living and Nursing Homes.

Note the same draw pattern (very small, low, medium and high draw) should be used for both baseline and efficient units.

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[417]
Residential Electric Storage Water Heaters ≤ 75,000 Btu/h	≤55 gallon tanks	Very small	UEF = 0.8808 – (0.0008 * Rated Storage Volume in Gallons)
		Low	UEF = 0.9254 – (0.0003 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.9307 – (0.0002 * Rated Storage Volume in Gallons)
		High	UEF = 0.9349 – (0.0001 * Rated Storage Volume in Gallons)
	>55 gallon and ≤120 gallon tanks [418]	Very small	UEF = 1.9236 – (0.0011 * Rated Storage Volume in Gallons)
		Low	UEF = 2.0440 – (0.0011 * Rated Storage Volume in Gallons)
		Medium	UEF = 2.1171 – (0.0011 * Rated Storage Volume in Gallons)
		High	UEF = 2.2418 – (0.0011 * Rated Storage Volume in Gallons)
Residential Electric Instantaneous Water Heaters	≤12kW and ≤2 gal	All other	UEF = 0.91
		High	UEF = 0.92
Residential-duty Commercial Electric Instantaneous Water Heaters	> 12kW and ≤58.6 kW and ≤2 gal	All	UEF = 0.80

Draw patterns are based on first hour rating (gallons) for storage tanks and maximum flow (GPM) for instantaneous as shown below:[419]

Storage Water Heater Draw Pattern	
Draw Pattern	**First Hour Rating (gallons)**
Very Small	≥ 0 and < 18
Low	≥ 18 and < 51
Medium	≥ 51 and < 75
High	≥ 75

Instantaneous Water Heater Draw Pattern	
Draw Pattern	**Max GPM**
Very Small	≥ 0 and < 1.7
Low	≥ 1.7 and < 2.8
Medium	≥ 2.8 and < 4
High	≥ 4

UEF_{eff} = Rated efficiency of efficient water heater expressed as Uniform Energy Factor (UEF)

= Actual

3412 = Converts Btu to kWh

$HPWHWasteheat_{cool}$ = Heat Pump Water Heater Only - Cooling savings from conversion of heat in building to water heat[420]

[417] All Residential sized Federal Standards are from DOE Standard 10 CFR 430, Residential-Duty and Commercial Federal Standard are from DOE Standard 10 CFR 431.

[418] It is assumed that tanks <75,000Btu/h and >55 gallons will not be eligible measures due to the high baseline.

[419] Definitions provided in 10 CFR 430, Subpart B, Appendix E, Section 5.4.1.

[420] This algorithm calculates the heat removed from the air by subtracting the HPWH electric consumption from the total water heating energy delivered. This is then adjusted to account for location of the HP unit and the coincidence of the waste heat with cooling requirements, the efficiency of the central cooling, and latent cooling demands.

$$= \left[\frac{\left((T_{OUT} - T_{IN}) * HotWaterUse_{Gallon} * \gamma Water * 1 * \left(1 - \frac{1}{UEF_{Eff}}\right)\right) * LF * 25\% * LM}{COP_{COOL} * 3412} \right] * Cool$$

Where:

LF = Location Factor
= 1.0 for HPWH installation in a conditioned space
= 0.5 for HPWH installation in an unknown location[421]
= 0.0 for installation in an unconditioned space

25% = Portion of reduced waste heat that results in cooling savings[422]

COP_{COOL} = COP of Central Air Conditioner
= Actual - If unknown, assume 3.25 (11.1 SEER2 / 3.412) [423]

LM = Latent multiplier to account for latent cooling demand
= 1.33 [424]

Cool = 1 if building has central cooling, 0 if not cooled

$HPWHWasteheat_{Heat}$ = Heat Pump Water Heater Only - Heating cost from conversion of heat in building to water heat (dependent on heating fuel)

$$= \left(\frac{\left((T_{OUT} - T_{IN}) * HotWaterUse_{Gallon} * \gamma Water * 1 * \left(1 - \frac{1}{UEF_{Eff}}\right)\right) * \text{LF} * 35\%}{\text{COP}_{\text{HEAT}} * 3412} \right) * \text{ElectricHeat}$$

Where:

35% = Portion of reduced waste heat that results in increased heating load[425]

COP_{HEAT} = COP of electric heating system
= Actual system efficiency including duct loss - If not available, use:

[421] Note unconditioned means a space that is not intentionally heated via furnace vents or boiler radiators. The presence of and/or leakage from a heating system in a space doesn't in itself imply the space is conditioned.
[422] This is estimated based on the percentage of lighting savings that result in reduced cooling loads (lighting is used as a proxy for hot water heating since load shapes suggest their seasonal usage patterns are similar). This is based on the WHFe for unknown non-residential buildings (1.08) and assuming an average cooling COP of 3.08 (1.08 = 1 + 0.246/3.08).
[423] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER value converted to SEER2 by multiplying by 0.95 and multiplied by 0.95 distribution efficiency.
[424] A sensible heat ratio (SHR) of 0.75 corresponds to a latent multiplier of 4/3 or 1.33. SHR of 0.75 for typical split system from page 10 of "Controlling Indoor Humidity Using Variable-Speed Compressors and Blowers" by M. A. Andrade and C. W. Bullard, 1999: www.ideals.illinois.edu/bitstream/handle/2142/11894/TR151.pdf
[425] This is estimated based on the percentage of lighting savings that result in increased heating loads (lighting is used as a proxy for hot water heating since load shapes suggest their seasonal usage patterns are similar). The WHFh for unknown non-residential buildings is 35%.

System Type	HSPF2 Estimate	ηHeat (Effective COP Estimate) (HSPF2/3.413)*0.95 (Distribution Efficiency)
Heat Pump	7.37[426]	2.05
Resistance	N/A	1

ElectricHeat = 1 if building is electrically heated, 0 if not

For example, for a 50 gallon, 95% UEF storage unit installed in a 1500 ft^2 restaurant:

ΔkWh = ((125 – 50.7) * ((1,500/1,000) * 44,439) * 8.33 * 1 * (1/0.88 - 1/0.95))/3412 + 0 + 0

= 1012 kWh

Electric units > 12kW:

T_{air} = Ambient Air Temperature

= 70°F

V = Rated tank volume in gallons

= Actual

$SL_{elecbase}$ = Standby loss of electric baseline unit (%/hr)

= 0.30 + 27/V

SL_{eff} = Nameplate standby loss of new water heater, in BTU/h

8766 = Hours per year

For example, >12kW, 100 gallon storage unit with rated standby loss of 0.5 %/hr:

SLbase = 0.3 + (27 / 100)

= 0.57%/hr

ΔkWh = (((125 – 70) * 100 * 8.33 * 1 * (0.57- 0.5)/100) * 8766)/3412

= 82.4 kWh

Gas units:

100,000 = Converts Btu to Therms

$EF_{gasbase}$ = Rated efficiency of baseline water heater (expressed as Uniform Energy Factor (UEF) or Thermal Efficiency as provided below).

Note the same draw pattern (very small, low, medium and high draw) should be used for both baseline and efficient units.

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[427]
Residential	≤55 gallon tanks	Very small	UEF = 0.3456 – (0.0020 * Rated Storage Volume in Gallons)

[426] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note HSPF value converted to HSPF2 by multiplying by 0.85.

[427] All Residential sized Federal Standards are from DOE Standard 10 CFR 430, Residential-Duty and Commercial Federal Standard are from DOE Standard 10 CFR 431.

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[427]
Gas Storage Water Heaters ≤75,000 Btu/h		Low	UEF = 0.5982 – (0.0019 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6483 – (0.0017 * Rated Storage Volume in Gallons)
		High	UEF = 0.6920 – (0.0013 * Rated Storage Volume in Gallons)
	>55 gallon and ≤100 gallon tanks	Very small	UEF = 0.6470 – (0.0006 * Rated Storage Volume in Gallons)
		Low	UEF = 0.7689 – (0.0005 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.7897 – (0.0004 * Rated Storage Volume in Gallons)
		High	UEF = 0.8072 – (0.0003 * Rated Storage Volume in Gallons)
Residential-duty Commercial High Capacity Storage Gas-Fired Storage Water Heaters > 75,000 Btu/h	≤120 gallon tanks	Very small	UEF = 0.2674 – (0.0009 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5362 – (0.0012 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6002 – (0.0011 * Rated Storage Volume in Gallons)
		High	UEF = 0.6597 – (0.0009 * Rated Storage Volume in Gallons)
Commercial Gas Storage Water Heaters >75,000 Btu/h and ≤155,000 Btu/h	>120 gallon tanks	All	80% $E_{thermal}$, Standby Losses = (Q /800 + 110√Rated Storage Volume in Gallons)
Commercial Gas Storage Water Heaters >155,000 Btu/h			
Residential Gas Instantaneous Water Heaters ≤ 200,000 Btu/h	≤2 gal	Very low	UEF = 0.80
		All other	UEF = 0.81
Commercial Gas Instantaneous Water Heaters > 200,000 Btu/h	<10 gal	All	80% $E_{thermal}$
	≥10 gal	All	78% $E_{thermal}$

Draw patterns are based on first hour rating (gallons) for storage tanks and maximum flow (GPM) for instantaneous as shown below:[428]

Storage Water Heater Draw Pattern	
Draw Pattern	**First Hour Rating (gallons)**
Very Small	≥ 0 and < 18
Low	≥ 18 and < 51
Medium	≥ 51 and < 75
High	≥ 75

Instantaneous Water Heater Draw Pattern	
Draw Pattern	**Max GPM**
Very Small	≥ 0 and < 1.7
Low	≥ 1.7 and < 2.8
Medium	≥ 2.8 and < 4

$HPWHWasteHeat_{GasHeat}$ = Heat Pump Water Heater Only - Heating cost from conversion of heat in building to water heat (dependent on heating fuel)

[428] Definitions provided in 10 CFR 430, Subpart B, Appendix E, Section 5.4.1.

$$= \left(\frac{\left((T_{OUT} - T_{IN}) * HotWaterUse_{Gallon} * \gamma Water * 1 * \left(1 - \frac{1}{UEF_{Eff}} \right) \right) * \text{LF} * 35\%}{100{,}000 * \eta Heat} \right) * (1 - \text{ElectricHeat})$$

ηHeat = Heating system efficiency including duct loss

= Actual. If unknown assume 0.821.[429]

Where:

$SL_{gasbase}$ = Standby loss of gas baseline unit (Btu/h)

$= Q/800 + 110\sqrt{V}$

Q = Nameplate input rating in Btu/h

V = Rated volume in gallons

SL_{eff} = Nameplate standby loss of new water heater, in Btu/h

8766 = Hours per year

For example, for a 200,000 Btu/h, 150 gallon, 90% UEF storage unit with rated standby loss of 1,029 BTU/h installed in a 1,500 ft^2 restaurant:

ΔTherms = ((125 – 50.7) * ((1,500/1,000) * 44,439) * 8.33 * 1 * (1/0.8 - 1/0.9))/100,000

= 57.3 Therms

$\Delta Therms_{Standby}$ = (((200,000/800 + 110 * √150) – 1,029) * 8,766)/100,000

= 49.8 Therms

ΔThermsTotal = 57.3 + 49.8

= 107.1 Therms

[429] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

Fuel switch: For example, a 160,000 Btu/h, 120 gallon, 80% UEF storage unit with rated standby loss of 1405 BTU/h installed in a 1500 ft^2 restaurant (with gas heat 85% AFUE and cooling) is replaced with a 120 gallon HPWH with medium draw (UEF = 2.1171 – (0.0011 * 100) = 2.0) and standby loss rate of 0.5%/hr installed in a unknown location.

GasConsumptionReplaced = (((125 – 50.7) * ((1,500/1,000) * 44,439) * 8.33 * 1 * 1/0.8)/1,000,000) + ((1,405 * 8,766)/1,000,000)

= 63.8 MMBtu

ElectricConsumptionAdded = (((125 – 50.7) * ((1,500/1,000) * 44,439) * 8.33 * 1 * 1/2.0)/1,000,000) + ((((125 – 50.7) * 120 * 8.33 * 1 * 0.5/100) * 8766)/1,000,000)

= 23.9 MMBtu

$HPWHWasteHeat_{cool}$ = ((125 – 50.7) * ((1,500/1,000) * 44,439) * 8.33 * 1 * (1 - 1/2.0) * 0.5 * 0.25 * 1.33) / (3.08 * 3412 * 1)

= 326 kWh

HPWHWasteHeatGasHeat = ((125 – 50.7) * ((1,500/1,000) * 44,439) * 8.33 * 1 * (1 - 1/2.0) * 0.5 * 0.35) / (100,000 * 0.85 * 1)

= 42 Therms

SiteEnergySavings (MMBTUs) = 63.8 – 23.9 + (326 * 0.003412) – (42 * 0.1)

= 36.8 MMBtu

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh}{Hours} * CF$$

Where:

Hours = Full load hours of water heater

= 6,461 [430]

CF = Summer Peak Coincidence Factor for measure

= 0.925 [431]

For example, >12kW, 100 gallon storage unit with rated standby loss of 0.5 %/hr:

ΔkW = 82.4 / 6,461 * 0.925

= 0.0118 kW

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

DEEMED O&M COST ADJUSTMENT CALCULATION

The deemed O&M cost adjustment for a tankless heaters is $100.[432]

[430] Full load hours assumption based on Wh/Max W Ratio from Itron eShape data for Missouri, calibrated to Illinois loads.
[431] Coincidence factor based on Average W in peak period/Max W from Itron eShape data for Missouri, calibrated to Illinois loads.
[432] Water heaters (WH) require annual maintenance. There are different levels of effort for annual maintenance depending if the unit is gas or electric, tanked or tankless. Electric and gas tank water heater manufacturers recommend an annual tank

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

Electric units ≤12 kW:

ΔTherms = [GasConsumptionReplaced]

$$= \left[\frac{(T_{out} - T_{in}) \ * \ HotWaterUse_{Gallon} * \gamma Water * 1 * \left(\frac{1}{UEF_{gasbase}}\right)}{100{,}000}\right]$$

ΔkWh = [ElectricConsumptionAdded]

$$= -\left[\frac{(T_{out} - T_{in}) \ * \ HotWaterUse_{Gallon} * \gamma Water * 1 * \left(\frac{1}{UEF_{Eff}}\right)}{3{,}412} + HPWHWasteHeat_{cool} - HPWHWasteHeat_{heat}\right]$$

Electric units > 12kW and gas units >75,000 Btu/h:

ΔTherms = [GasConsumptionReplaced]

$$= \left[\frac{(T_{out} - T_{in}) \ * \ HotWaterUse_{Gallon} * \gamma Water * 1 * \left(\frac{1}{UEF_{gasbase}}\right)}{100{,}000} + \frac{(SL_{gasbase} * 8766)}{100{,}000}\right] - (\text{HPWHWasteHeat}_{heat(gas)})$$

ΔkWh = [ElectricConsumptionAdded]

$$= -\left[\frac{(T_{out} - T_{in}) \ * \ HotWaterUse_{Gallon} * \gamma Water * 1 * \left(\frac{1}{UEF_{Eff}}\right)}{1{,}000{,}000} + \frac{\left((T_{out} - T_{air}) * V * \gamma Water * 1 * \left(\frac{SL_{eff}}{100}\right)\right) * 8766}{1{,}000{,}000}\right] + (\text{HPWHWasteHeat}_{cool} \ * \ 0.003412) - (\text{HPWHWasteHeat}_{heat(electric)})$$

drain to clear sediments. Also recommended are "periodic" inspections by qualified service professionals of operating controls, heating element and wiring for electric WHs and thermostat, burner, relief valve internal flue-way and venting systems for gas WHs. Tankless WH require annual maintenance by licensed professionals to clean control compartments, burners, venting system and heat exchangers. This information is from WH manufacturer product brochures including GE, Rennai, Rheem, Takagi and Kenmore. References for incremental O&M costs were not found. Therefore the incremental cost of the additional annual maintenance for tankless WH is estimated at $100.

MEASURE CODE: CI-HWE-STWH-V12-260101

REVIEW DEADLINE: 1/1/2027

4.3.2 Low Flow Faucet Aerators

DESCRIPTION

This measure relates to the direct installation of a low flow faucet aerator in a commercial building. Expected applications include small business, office, restaurant, or motel. Health care-specific inputs are defined for Laminar Flow Restrictor (LFR) devices. For multifamily or senior housing, the residential low flow faucet aerator should be used.

This measure was developed to be applicable to the following program types, DI, KITS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be an energy efficient faucet aerator, for bathrooms rated at 1.5 gallons per minute (GPM) or less, or for kitchens rated at 2.2 GPM or less. For LFR devices, the installed equipment must be a device rated at 2.2 GPM or less. Savings are calculated on an average savings per faucet fixture basis.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is assumed to be a standard bathroom or kitchen faucet aerator. For LFR devices, the baseline condition is assumed to be no aerator at all, due to the contamination risk caused by faucet aerators in health care facilities and the baseline flow rate is assumed to be 3.74 GPM[433]. Note if flow rates are measured, for example through a Direct Install program, then actual baseline flow rates should be used as opposed to the deemed values.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[434]

DEEMED MEASURE COST

The actual full install cost (including labor) for this measure should be used. If unknown assume $8 for faucet aerators[435] and $14.27 for LFR devices.[436]

LOADSHAPE

Loadshape C02 - Commercial Electric DHW

COINCIDENCE FACTOR

The coincidence factor for this measure is dependent on building type as presented below.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Note these savings are *per faucet retrofitted.*[437]

$$\Delta\text{kWh} = \%ElectricDHW * ((GPM_base - GPM_low)/GPM_base) * Usage * EPG_electric * ISR$$

[433] Workpaper WPSCGNRWH150827A, Laminar Flow Restrictors For Hospitals and Health Care Facilities.
[434] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.
[435] Direct-install price per faucet assumes cost of aerator and install time. (2011, Market research average of $3 and assess and install time of $5 (20min @ $15/hr).
[436] Direct install price per faucet assumes cost of LFR ($7.27) and install time ($7) (Southern California Gas Company, Workpaper WPSCGNRWH150827A Revision #0, September, 2015).
[437] This algorithm calculates the amount of energy saved per aerator by determining the fraction of water consumption savings for the upgraded fixture. Due to the distribution of water consumption by fixture type, as well as the different number of fixtures in a building, several variables must be incorporated.

Where:

%ElectricDHW = proportion of water heating supplied by electric resistance heating

DHW Fuel	%Electric_DHW
Electric	100%
Fossil Fuel	0%
Unknown	32%[438]

GPM_base = Average flow rate, in gallons per minute, of the baseline faucet "as-used"

= 1.39,[439] or custom based on metering studies,[440] or, if measured during DI:

= Measured full throttle flow * 0.83 throttling factor[441]

Baseline for LFRs[442] = 3.74 * 0.83 = 3.10

GPM_low = Average flow rate, in gallons per minute, of the low-flow faucet aerator "as-used"

= 0.94,[443] or custom based on metering studies,[444] or, if measured during DI:

= Rated full throttle flow * 0.95 throttling factor[445]

For LFRs[446] = 2.2 * 0.95 = 2.09

Usage = Estimated usage of mixed water (mixture of hot water from water heater line and cold water line) per faucet (gallons per year)

= If data is available to provide a reasonable custom estimate it should be used; if not, use the following defaults (or substitute custom information in to the calculation):

[438] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024.
[439] DeOreo, B., and P. Mayer. Residential End Uses of Water Study Update. Forthcoming. ©2015 Water Research Foundation. Reprinted With Permission.
[440] Measurement should be based on actual average flow consumed over a period of time rather than a onetime spot measurement for maximum flow. Studies have shown maximum flow rates do not correspond well to average flow rate due to occupant behavior which does not always use maximum flow.
[441] 2008, Schultdt, Marc, and Debra Tachibana. Energy related Water Fixture Measurements: Securing the Baseline for Northwest Single Family Homes. 2008 ACEEE Summer Study on Energy Efficiency in Buildings. Page 1-265.
[442] Using measured flow rate assumption from Workpaper WPSCGNRWH150827A, Laminar Flow Restrictors For Hospitals and Health Care Facilities.
[443] Average retrofit flow rate for kitchen and bathroom faucet aerators from sources 2, 4, 5, and 7. This accounts for all throttling and differences from rated flow rates. Assumes all kitchen aerators at 2.2 gpm or less and all bathroom aerators at 1.5 gpm or less. The most comprehensive available studies did not disaggregate kitchen use from bathroom use, but instead looked at total flow and length of use for all faucets. This makes it difficult to reliably separate kitchen water use from bathroom water use. It is possible that programs installing low flow aerators lower than the 2.2 gpm for kitchens and 1.5 gpm for bathrooms will see a lower overall average retrofit flow rate.
[444] Measurement should be based on actual average flow consumed over a period of time rather than a onetime spot measurement for maximum flow. Studies have shown maximum flow rates do not correspond well to average flow rate due to occupant behavior which does not always use maximum flow.

Motel	20	room	25%	1	faucet per room	365	1,825
Hotel	14	room	25%	1	faucet per room	365	1,278
Other	1	employee	100%	20	employees per faucet	250	5,000

EPG_electric = Energy per gallon of mixed water used by faucet (electric water heater)

= (8.33 * 1.0 * (WaterTemp - SupplyTemp)) / (RE_electric * 3412)

= 0.0879 kWh/gal for Bath, 0.1054 kWh/gal for Kitchen, 0.1477 kWh/gal for LFRs, 0.1004 kWh/gal for unknown

8.33 = Specific weight of water (lbs/gallon)

1.0 = Heat Capacity of water (btu/lb-°F)

WaterTemp = Assumed temperature of mixed water

= 86°F for Bath, 93°F for Kitchen, 91°F for Unknown,[450] 110°F for health care facilities[451]

SupplyTemp = Assumed temperature of water entering building

= 50.7°F [452]

RE_electric = Recovery efficiency of electric water heater

= 98% [453]

[447] Table 2-45 Chapter 49, Service Water Heating, 2007 ASHRAE Handbook, HVAC Applications.

[448] Estimated based on data provided in Appendix E; "Waste Not, Want Not: The Potential for Urban Water Conservation in California", Pacific Institute, November 2003.

[449] Based on review of the Illinois plumbing code (Employees and students per faucet). Retail, grocery, warehouse and health are estimates. Meals per faucet estimated as 4 bathroom and 3 kitchen faucets and average meals per day of 250 (based on California study above) – 250/7 = 36. Fast food assumption estimated.

[450] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group. If the aerator location is unknown an average of 91% should be used which is based on the assumption that 70% of household water runs through the kitchen faucet and 30% through the bathroom (0.7*93)+(0.3*86)=0.91.

[451] Southern California Gas Company, Workpaper WPSCGNRWH150827A Revision #0, September, 2015.

[452] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[453] Electric water heaters have recovery efficiency of 98%, as sourced from available products on the AHRI Certification Directory.

3412 = Converts Btu to kWh (Btu/kWh)

ISR = In service rate of faucet aerators dependant on install method as listed in table below:

Selection	ISR
Direct Install - Deemed[454]	0.95
Efficiency Kits - Default[455]	0.50
Leave-Behind Kit[456]	0.91

For example, a direct installed kitchen faucet in a large office with electric DHW:

ΔkWh = 1 * ((1.39 – 0.94)/1.39) * 11,250 * 0.1054 * 0.95

= 364.7 kWh

For example, a direct installed bathroom faucet in an Elementary School with electric DHW:

ΔkWh = 1 * ((1.39 – 0.94)/1.39) * 3,000 * 0.0879 * 0.95

= 81.1 kWh

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) \ / \ 1{,}000{,}000 \ * \ E_{water\ total}$$

Where

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

=5,010[457]

For example, a direct installed faucet in a large office:

ΔWater (gallons) = ((1.39 – 0.94)/1.39) * 11,250 * 0.95

= 3,640 gallons

ΔkWh_{water} = 3,640/1,000,000*5,010

= 18 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (\Delta kWh \ / \ Hours) \ * \ CF$$

Where:

[454] ComEd Energy Efficiency/Demand Response Plan: Plan Year 2 (6/1/2009-5/31/2010) Evaluation Report: All Electric Single Family Home Energy Performance Tune-Up Program, December 21, 2010, Table 3-8.

[455] Analysis of CY2018, CY2019, and CY2020 Small Business Kit participant survey installation data. Use if annual survey data is not available or applicable. Please see file "SB Kits Survey Analysis TRMv10 Support.xlsx"

[456] Based on DCEO STEP Program GPY5 evaluation report for showerheads and aerators. Guidehouse, *In-Service Rates for a CY2020 Business Remote Assessment Path for Customer Installed Measures*, August 21, 2020. Please see file "Business Program Remote Assessment and Install ISR Memo 2020-08-21.docx"

[457] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

ΔkWh = calculated value above on a per faucet basis. Note do not include the secondary savings in this calculation.

Hours = Annual electric DHW recovery hours for faucet use

= (Usage * 0.44 [458])/GPH

= Calculate if usage is custom, if using default usage use:

Building Type	Annual Recovery Hours
Small Office	20
Large Office	92
Fast Food Rest	78
Sit-Down Rest	129
Retail	30
Grocery	30
Warehouse	20
Elementary School	24
Jr High/High School	73
Health	134
Motel	15
Hotel	10
Other	41

Where:

GPH = Gallons per hour recovery of electric water heater calculated for 89.3F temp rise (140-50.7), 98% recovery efficiency, and typical 12kW electric resistance storage tank.

= 53.9

CF = Coincidence Factor for electric load reduction

= Dependent on building type[459]

Building Type	Coincidence Factor
Small Office	0.0064
Large Office	0.0288
Fast Food Rest	0.0084
Sit-Down Rest	0.0184
Retail	0.0043
Grocery	0.0043
Warehouse	0.0064
Elementary School	0.0096
Jr High/High School	0.0288
Health	0.0144
Motel	0.0006

[458] 44% is the proportion of hot 140°F water mixed with 50.7°F supply water to give 90°F mixed faucet water.

[459] Calculated as follows: Assumptions for percentage of usage during peak period (1-5pm) were made and then multiplied by 65/365 (65 being the number of days in peak period) and by the number of total annual recovery hours to give an estimate of the number of hours of recovery during peak periods. There are 260 hours in the peak period so the probability you will see savings during the peak period is calculated as the number of hours of recovery during peak divided by 260. See 'C&I Faucet Aerator.xls' for details.

Building Type	Coincidence Factor
Hotel	0.0004
Other	0.0128

For example, a direct installed kitchen faucet in a large office with electric DHW:

ΔkW = 364.7/92 * 0.0288

= 0.1142 kW

For example, a direct installed bathroom faucet in an Elementary School with electric DHW:

ΔkW = 81.1/24 * 0.0096

= 0.0324 kW

FOSSIL FUEL SAVINGS

$$\Delta\text{Therms} = \%FossilDHW * ((GPM_base - GPM_low)/GPM_base) * Usage * EPG_gas * ISR$$

Where:

%FossilDHW = proportion of water heating supplied by fossil fuel heating

DHW Fuel	%Fossil_DHW
Electric	0%
Fossil Fuel	100%
Unknown	68%[460]

EPG_gas = Energy per gallon of mixed water used by faucet (gas water heater)

= (8.33 * 1.0 * (WaterTemp - SupplyTemp)) / (RE_gas * 100,000)

= 0.0044 Therm/gal for Bath, 0.0053 Therm/gal for Kitchen, 0.0074 Therm/gal for LFRs, 0.0050 Therm/gal for unknown

Where:

RE_gas = Recovery efficiency of gas water heater

= 67% [461]

100,000 = Converts Btus to Therms (Btu/Therm)

Other variables as defined above.

[460] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024.

[461] Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 75%. Commercial properties are more similar to MF homes than SF homes. MF hot water is often provided by a larger commercial boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of .59 and the .75 for single family home. An average is used for this analysis by default.

For example, a direct installed kitchen faucet in a large office with gas DHW:

ΔTherms = 1 * ((1.39 – 0.94)/1.39) * 11,250 * 0.0053 * 0.95

= 18.3 Therms

For example, a direct installed bathroom faucet in an Elementary School with gas DHW:

ΔTherms = 1 * ((1.39 – 0.94)/1.39) * 3,000 * 0.0044 * 0.95

= 4.06 Therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

ΔWater (gallons) = $((GPM_base - GPM_low)/GPM_base) * Usage * ISR$

Variables as defined above.

For example, a direct installed faucet in a large office:

ΔWater (gallons) = ((1.39 – 0.94)/1.39) * 11,250 * 0.95

= 3,640 gallons

For example, a direct installed faucet in an Elementary School:

ΔWater (gallons) = ((1.39 – 0.94)/1.39) * 3,000 * 0.95

= 971 gallons

REVIEW DEADLINE: 1/1/2030

4.3.3 Low Flow Showerheads

DESCRIPTION

This measure relates to the direct installation of a low flow showerhead in a commercial building. Expected applications include small business, office, restaurant, or small motel. For multifamily or senior housing, the residential low flow showerhead should be used.

This measure was developed to be applicable to the following program types: DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be an energy efficient showerhead rated at 2.0 gallons per minute (GPM) or less. Savings are calculated on a per showerhead fixture basis.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is assumed to be a standard showerhead rated at 2.5 GPM.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[462]

DEEMED MEASURE COST

The actual full install cost (including labor) should be used. If unknown, assume $12 per showerhead.[463]

LOADSHAPE

Loadshape C02 - Commercial Electric DHW

COINCIDENCE FACTOR

The coincidence factor for this measure is assumed to be 2.78%.[464]

Algorithm

CALCULATION OF SAVINGS [465]

ELECTRIC ENERGY SAVINGS

Note these savings are per showerhead fixture.

$$\Delta kWh = \%ElectricDHW * ((GPM_base * L_base - GPM_low * L_low) * NSPD * 365.25) * EPG_electric * ISR$$

Where:

%ElectricDHW = proportion of water heating supplied by electric resistance heating

[462] Table C-6, Measure Life Report, Residential and Commercial/Industrial Lighting and HVAC Measures, GDS Associates, June 2007. Evaluations indicate that consumer dissatisfaction may lead to reductions in persistence, particularly in Multi-Family.
[463] Direct-install price per showerhead assumes cost of showerhead (Market research average of $7 and assess and install time of $5 (20min @ $15/hr).
[464] Calculated as follows: Assume 11% showers take place during peak hours (as sourced from "Analysis of Water Use in New Single Family Homes, Aquacraft Water Engineering and Management, January 2011). There are 65 days in the summer peak period, so the percentage of total annual aerator use in peak period is 0.11*65/365 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 369 = 7.23 hours of recovery during peak period. There are 260 hours in the peak period, so the probability you will see savings during the peak period is 7,23/260 = 0.0278.
[465]Based on excel spreadsheet 120911.xls …on IL-TRM SharePoint.

= 1 if electric DHW; 0 if fuel DHW; if unknown, assume 32%[466]

GPM_base = Flow rate of the baseline showerhead

= 2.67 for Direct-install programs[467]

GPM_low = As-used flow rate of the low flow showerhead, which may, as a result of measurements of program evaulations deviate from rated flows, see table below:

Rated Flow
2.0 GPM
1.75 GPM
1.5 GPM
Custom or Actual[468]

L_base = Shower length in minutes with baseline showerhead

= 8.20 min[469]

L_low = Shower length in minutes with low-flow showerhead

= 8.20 min[470]

365.25 = Days per year, on average.

NSPD = Estimated number of showers taken per day for one showerhead

EPG_electric = Energy per gallon of hot water supplied by electric

= (8.33 * 1.0 * (ShowerTemp - SupplyTemp)) / (RE_electric * 3412)

= (8.33 * 1.0 * (101 – 50.7)) / (0.98 * 3412)

= 0.125 kWh/gal

8.33 = Specific weight of water (lbs/gallon)

1.0 = Heat Capacity of water (btu/lb-°F)

ShowerTemp = Assumed temperature of water

= 101°F [471]

SupplyTemp = Assumed temperature of water entering house

= 50.7°F [472]

RE_electric = Recovery efficiency of electric water heater

[466] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024.
[467] Based on measured data from Ameren IL EM&V of Direct-Install program. Program targets showers that are rated 2.5 GPM or above.
[468] Note that actual values may be either a) program-specific minimum flow rate, or b) program-specific evaluation-based value of actual effective flow-rate due to increased duration or temperatures. The latter increases in likelihood as the rated flow drops and may become significant at or below rated flows of 1.5 GPM. The impact can be viewed as the inverse of the throttling described in the footnote for baseline flowrate.
[469] Representative value from sources 1, 2, 3, 4, 5, and 6 (See Source Table at end of measure section).
[470] Set equal to L_base.
[471] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.
[472] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

= 98% [473]

3412 = Converts Btu to kWh (btu/kWh)

ISR = In service rate of showerhead

= Dependant on program delivery method as listed in table below

Selection	ISR
Direct Install or Guided Self-Install	0.98[474]
Leave-Behind Kit	0.94[475]

For example, a direct-installed 1.5 GPM showerhead in an office with electric DHW where the number of showers is estimated at 3 per day:

ΔkWh = 1 * ((2.67*8.20)- (1.5*8.20)) * 3*365.25) *0.125 * 0.98

= 1288 kWh

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) \ / \ 1{,}000{,}000 \ * \ E_{water\ total}$$

Where

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

=5,010[476]

For example, a direct-installed 1.5 GPM showerhead in an office with where the number of showers is estimated at 3 per day:

ΔWater (gallons) = ((2.67 * 8.20)-(1.5 * 8.20)) * 3 * 365.25 * 0.98

= 10,302 gallons

ΔkWh_{water} = 10,302/1,000,000*5,010

= 52 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh/Hours \ * \ CF$$

Where:

ΔkWh = calculated value above. Note do not include the secondary savings in this calculation.

[473] Electric water heaters have recovery efficiency of 98%, as sourced from available products on the AHRI Certification Directory.

[474] Deemed values are from ComEd Energy Efficiency/ Demand Response Plan: Plan Year 2 (6/1/2009-5/31/2010) Evaluation Report: All Electric Single Family Home Energy Performance Tune-Up Program Table 3-8. Alternative ISRs may be developed for program delivery methods based on evaluation results.

[475] Based on DCEO STEP Program GPY5 evaluation report for showerheads and aerators. Guidehouse, *In-Service Rates for a CY2020 Business Remote Assessment Path for Customer Installed Measures*, August 21, 2020.

[476] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

Hours = Annual electric DHW recovery hours for showerhead use

= $((GPM_base * L_base) * NSPD * 365.25) * 0.608$ [477] / GPH

Where:

GPH = Gallons per hour recovery of electric water heater calculated for 89.3F temp rise (140-50.7), 98% recovery efficiency, and typical 12kW electric resistance storage tank.

= 53.9

CF = Coincidence Factor for electric load reduction

= 0.0278 [478]

For example, a direct-installed 1.5 GPM showerhead in an office with electric DHW where the number of showers is estimated at 3 per day:

ΔkW = (1288 / 271)*0.0278

= 0.132 kW

FOSSIL FUEL SAVINGS

ΔTherms = $\%FossilDHW * ((GPM_base * L_base - GPM_low * L_low) * NSPD * 365.25) * EPG_gas * ISR$

Where:

%FossilDHW = proportion of water heating supplied by fossil fuel heating

DHW Fuel	%Fossil_DHW
Electric	0%
Fossil Fuel	100%
Unknown	68%[479]

EPG_gas = Energy per gallon of Hot water supplied by gas

= $(8.33 * 1.0 * (ShowerTemp - SupplyTemp)) / (RE_gas * 100{,}000)$

= 0.0063 Therm/gal

Where:

RE_gas = Recovery efficiency of gas water heater

= 67% [480]

[477] 60.8% is the proportion of hot 140°F water mixed with 50.7°F supply water to give 105°F shower water.

[478] Calculated as follows: Assume 11% showers take place during peak hours (as sourced from "Analysis of Water Use in New Single Family Homes, Aquacraft Water Engineering and Management, January 2011). There are 65 days in the summer peak period, so the percentage of total annual aerator use in peak period is 0.11*65/365.25 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 369 = 7.23 hours of recovery during peak period where 369 equals the average annual electric DHW recovery hours for showerhead use including SF and MF homes with Direct Install and Retrofit/TOS measures. There are 260 hours in the peak period so the probability you will see savings during the peak period is 7.23/260 = 0.0278.

[479] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024.

[480] Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 75%. Commercial properties are more similar to MF homes than SF homes. MF hot water is often

100,000 = Converts Btus to Therms (btu/Therm)

Other variables as defined above.

For example, a direct-installed 1.5 GPM showerhead in an office with gas DHW where the number of showers is estimated at 3 per day:

ΔTherms = 1.0 * ((2.67 *8.2) – (1.5 * 8.2)) * 3 * 365.25 * 0.0063 * 0.98

= 64.9 therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

ΔWater (gallons) = $((GPM_base * L_base - GPM_low * L_low) * NSPD * 365.25 * ISR$

Variables as defined above

For example, a direct-installed 1.5 GPM showerhead in an office with where the number of showers is estimated at 3 per day:

ΔWater (gallons) = ((2.67 * 8.20)-(1.5 * 8.20)) * 3 * 365.25 * 0.98

= 10,302 gallons

REVIEW DEADLINE: 1/1/2029

provided by a larger commercial boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of .59 and the .75 for single family home. An average is used for this analysis by default.

4.3.4 Commercial Pool Covers

DESCRIPTION

This measure refers to the installation of covers on commercial use pools that are heated with gas-fired equipment located either indoors or outdoors. By installing pool covers, the heating load on the pool boiler will be reduced by reducing the heat loss from the water to the environment and the amount of actual water lost due to evaporation (which then requires additional heated water to make up for it). An additional benefit to pool covers are the electricity savings from the reduced fresh water required to replace the evaporated water.

The main source of energy loss in pools is through evaporation. This is particularly true of outdoor pools where wind plays a larger role. The point of installing pool covers is threefold. First, it will reduce convective losses due to the wind by shielding the water surface. Second, it will insulate the water from the colder surrounding air. And third, it will reduce radiative losses to the night sky. In doing so, evaporative losses will also be minimized, and the boiler will not need to work as hard in replenishing the pool with hot water to keep the desired temperature.

This measure can be used for pools that (1) currently do not have pool covers, (2) have pool covers that are past the useful life of the existing cover, or (3) have pool covers that are past their warranty period and have failed. Please note, IECC 2021 requires pool covers in outdoor applications, making this measure ineligible for new construction projects with outdoor pools. IECC 2021 has become effective statewide as of January 1, 2024, and is the baseline for all New Construction permits from that date onward. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

DEFINITION OF EFFICIENT EQUIPMENT

For indoor pools, the efficient case is the installation of an indoor pool cover with a 5 year warranty on an indoor pool that operates all year.

For outdoor pools, the efficient case is the installation of an outdoor pool cover with a 5 year warranty on an outdoor pool that is open through the summer season.

DEFINITION OF BASELINE EQUIPMENT

For indoor pools, the base case is an uncovered indoor pool that operates all year.

For outdoor pools, the base case is an outdoor pool that is uncovered and is open through the summer season.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The useful life of this measure is assumed to be 6 years.[481]

DEEMED MEASURE COST

The table below shows the costs for the various options and cover sizes. Since this measure covers a mix of various sizes, the average cost of these options is taken to be the incremental measure cost.[482] Costs are per square foot.

[481] The effective useful life of a pool cover is typically one year longer than its warranty period. SolaPool Covers. Pool Covers Website, FAQ- "How long will my SolaPool cover blanket last?". Pool covers are typically offered with 3 and 5 year warranties with at least one company offering a 6 year warranty. Conversation with Trade Ally. Knorr Systems.

[482] Pool Cover Costs: Lincoln Commercial Pool Equipment online catalog. Accessed 8/26/11.

Cover Size	Edge Style	
	Hemmed (indoor)	Weighted (outdoor)
1000-1,999 sq. ft.	$2.19	$2.24
2,000-2,999 sq. ft.	$2.01	$2.06
3,000+ sq. ft.	$1.80	$1.83
Average	$2.00	$2.04

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons)\ /\ 1{,}000{,}000\ *\ E_{water\ supply}$$

Where

$E_{water\ supply}$ = Water Supply Energy Factor (kWh/Million Gallons)

= 2,571[483]

For example,

2400ft^2 Indoor Swimming Pool:

ΔWater = $WaterSavingFactor\ x\ Size\ of\ Pool$

= 15.28 gal./ft^2/year x 2400 ft^2

= 36,672 gal./year

ΔkWhwater = $\Delta Water\ /\ 1{,}000{,}000\ *\ Ewater\ supply$

= 36,672 gal./year / 1,000,000 * 2,571 kWh/million gallons

= 96.3 kWh/year

2400ft^2 Outdoor Swimming Pool:

ΔWater = $WaterSavingFactor\ x\ Size\ of\ Pool$

= 8.94 gal./ft^2/year x 2400 ft^2

= 21,456 gal./year

ΔkWhwater = $\Delta Water\ /\ 1{,}000{,}000\ *\ E_{water\ supply}$

= 21,456 gal./year / 1,000,000 * 2,571 kWh/million gallons

= 55.2 kWh/year

[483] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'. Note since the water loss associated with this measure is due to evaporation and does not discharge into the wastewater system, only the water supply factor is used here.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

The calculations are based on modeling runs using RSPEC! Energy Smart Pools Software that was created by the U.S. Department of Energy. [484]

$$\Delta\text{Therms} = SavingFactor\ x\ Size\ of\ Pool$$

Where

Savings factor = dependant on pool location and listed in table below:[485]

Location	Therm / sq-ft
Indoor	2.61
Outdoor	1.01

Size of Pool = custom input

WATER IMPACT DESCRIPTIONS AND CALCULATION

$$\Delta\text{Water (gallons)} = WaterSavingFactor\ x\ Size\ of\ Pool$$

Where

WaterSavingFactor = Water savings for this measure dependant on pool location and listed in table below:[486]

Location	Annual Savings Gal / sq-ft
Indoor	15.28
Outdoor	8.94

Size of Pool = Custom input

DEEMED O&M COST ADJUSTMENT CALCULATION

There are no O&M cost adjustments for this measure.

MEASURE CODE: CI-HWE-PLCV-V06-250101

REVIEW DEADLINE: 1/1/2029

4.3.5 Tankless Water Heater – Measure combined with 4.3.1 Water Heater in Version 8

4.3.6 Ozone Laundry

DESCRIPTION

A new ozone laundry system(s) is added-on to new or existing commercial washing machine(s) using hot water heated with natural gas. The system generates ozone (O_3), a naturally occurring molecule, which helps clean fabrics by chemically reacting with soils in cold water. Adding an ozone laundry system(s) will reduce the amount of chemicals, detergents, and hot water needed to wash linens. Using ozone also reduces the total amount of water consumed, saving even more in energy.

Natural gas energy savings will be achieved at the hot water heater/boiler as they will be required to produce less hot water to wash each load of laundry. The decrease in hot water usage will increase cold water usage, but overall water usage at the facility will decrease.

Electric savings can be realized through reduced washer cycle length and reduced pumping load at the boiler feeding the commercial washers. The increased usage associated with operating the ozone system should also be accounted for when determining total kWh impact. Data reviewed for this measure characterization indicated that pumping savings should be accounted for, but washer savings and ozone generator consumption are comparatively so small that they can be ignored.

The reduced washer cycle length may decrease the dampness of the clothes when they move to the dryer. This can result in shorter runtimes which result in gas and electrical savings. However, at this time, there is inconclusive evidence that energy savings are achieved from reduced dryer runtimes so the resulting dryer effects are not included in this analysis. Additionally, there would be challenges verifying that dryer savings will be achieved throughout the life of the equipment.

This incentive only applies to the following facilities with on-premise laundry operations:

- Hotels/motels
- Fitness and recreational sports centers.
- Healthcare (excluding hospitals)
- Assisted living facilities
- Laundromats

Ozone laundry system(s) could create significant energy savings opportunities at other larger facility types with on-premise laundry operations (such as correctional facilities, universities, and staff laundries), however, the results included in this analysis are based heavily on past project data for the applicable facility types listed above and may not apply to facilities outside of this list due to variances in number of loads and average pound (lbs.)-capacity per project site. Projects at these facilities should continue to be evaluated through custom programs and the applicable facility types and the resulting analysis should be updated based on new information.

Laundromats are the only application where number of washing units needs to be used to calculate total site energy savings. All other applications use site assumptions to calculate total site savings.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

A new ozone laundry system(s) is added-on to new or existing commercial washing machine(s) using hot water heated with natural gas. The ozone laundry system(s) must transfer ozone into the water through:

- Venturi Injection
- Bubble Diffusion
- Additional applications may be considered upon program review and approval on a case by case basis
- For laundromats, the ozone laundry system(s) must be connected to both the hot and cold water inlets of the clothes washing machine(s) so that hot water is no longer provided to the clothes washer.

DEFINITION OF BASELINE EQUIPMENT

The base case equipment is a conventional washing machine system with no ozone generator installed. The washing machines are provided hot water from a gas-fired boiler.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure equipment effective useful life (EUL) is estimated at 10 years based on typical lifetime of the ozone generator's corona discharge unit.[487]

DEEMED MEASURE COST

The actual measure costs should be used if available. If not, the following deemed values should be used:

Application	Deemed Measure Cost
Laundromat	$25.53 / lbs capacity[488]
Hotel/Motel	$79.84 / lbs capacity[489]
Fitness and Recreation	
Healthcare	
Assisted Living	

LOADSHAPE

Loadshape C53 – Flat

COINCIDENCE FACTOR

Past project documentation and data collection is not sufficient to determine a coincidence factor for this measure. Value should continue to be studied and monitored through additional studies due to limited data points used for this determination.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Electric savings can be realized through reduced washer cycle length and reduced pumping load at the boiler feeding the commercial washers. There is also an increased usage associated with operating the ozone system. Data reviewed for this measure characterization indicated that while pumping savings is significant and should be accounted for, washer savings and ozone generator consumption are negligible, counter each other out and are well within the margin of error so these are not included to simplify the characterization.[490]

$$\Delta kWh_{PUMP} = HP * HP_{CONVERSION} * Hours * \%water_savings$$

Where:

[487] Aligned with other national energy efficiency programs and confirmed with national vendors

[488] Average cost per unit of capacity for laundromats was generated using data collected from previous Peoples Gas and North Shore Gas custom projects

[489] Average costs per unit of capacity were generated using data collected from existing ozone laundry projects that received incentives under the Non-Residential Retrofit Demand Reduction program (NRR-DR), as well as from the Nicor Custom Incentive Program, and the Nicor Emerging Technology Program (ETP). See referenced document Table 2 and RSMeans Mechanical Cost Data, 31st Annual Edition (2008)

[490] Washer savings were reviewed but were considered negligible and not included in the algorithm (0.00082 kWh / lbs-capacity, determined through site analysis through Nicor Emerging Technology Program (ETP) and confirmed with national vendors). Note that washer savings from Nicor's site analysis are smaller than those reported in a WI Focus on Energy case study (0.23kWh/100lbs, Hampton Inn Brookfield, November 2010). Electric impact of operating ozone generator (0.0021 kWh / lbs-capacity same source as washer savings) was also considered negligible and not included in calculations. Values should continue to be studied and monitored through additional studies due to limited data points used for this determination.

ΔkWh_{PUMP} = Electric savings from reduced pumping load

HP = Brake horsepower of boiler feed water pump;

= Actual, or use 5 HP if unknown[491]

$HP_{CONVERSION}$ = Conversion from Horsepower to Kilowatt

= 0.746

Hours = Actual associated boiler feed water pump hours

= Must be a custom calculation for laundromats, but 800 hours can be used for other applications if unknown[492]

%water_savings = water reduction factor: how much more efficient an ozone injection washing machine is compared to a typical conventional washing machine as a rate of hot and cold water reduction.

Application	%water_savings
Laundromat	10%[493]
Hotel/Motel	25%[494]
Fitness and Recreation	
Healthcare	
Assisted Living	

Using defaults above:

$\Delta kWh_{PUMP_LAUNDROMAT}$ = $5 * 0.746 * Hours * 0.10$

= $0.373\ kWh * Hours$

$\Delta kWh_{PUMP_All\ OTHER}$ = $5 * 0.746 * 800 * 0.25$

= $746\ kWh$

Default per pound: = $\Delta kWh_{PUMP} \ / \ Lbs - Capacity$

Where:

Lbs-Capacity = Total washer capacity measured in pounds of laundry

Application	Lbs-Capacity
Laundromat	Actual combined capacity of ozone connected washers
Hotel/Motel	254.38 lbs per site[495]
Fitness and Recreation	
Healthcare	

[491] Assumed average horsepower for boilers connected to applicable washer.

[492] Engineered estimate provided by CLEAResult review of Nicor custom projects. Machines spent approximately 7 minutes per hour filling with water and were in operation approximately 20 hours per day. Total pump time therefore estimated as 7/60 * 20 * 365 = 852 hours, and rounded down conservatively to 800 hours.

[493] Page 7, Laundries and Dry-Cleaning Operations, Watersmart Guidebook EBMUD_WaterSmart_Guide_Laundries_Dry-Cleaning_Operations.pdf.

[494] Average water reduction factors were generated using data collected from existing ozone laundry projects that received incentives under the Non-Residential Retrofit Demand Reduction program (NRR-DR). Table 6 summarizes data gathered from several NRR-DR projects, Nicor Custom projects, and Nicor ETP projects. Nicor Savings Numbers are associated with ACEE_AWE_Ozone Laundry / From Gas Savings Calculations.

[495] Average lbs-capacity per project site was generated using data collected from existing ozone laundry projects that received incentives under the Non-Residential Retrofit Demand Reduction program (NRR-DR), as well as from the Nicor Custom Incentive Program, and the Nicor Emerging Technology Program (ETP). See referenced document Table 2.

Application	Lbs-Capacity
Assisted Living	

$\Delta kWh_{PUMPALL\ OTHERS}$ per pound = 746/254.38

= 2.93 kWh/lb

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) / 1{,}000{,}000 * E_{water\ total}$$

Where:

$\Delta Water\ (gallons)_{LAUNDROMAT}$ = $239 * Lbs_Capacity$[496]

$\Delta Water\ (gallons)_{ALL\ OTHERS}$ = $464{,}946$[497]

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

=5,010[498]

Deemed savings using defaults:

$\Delta kWh_{water_LAUNDROMAT}$ = $(239 * Lbs - Cpacity)/1{,}000{,}000 * 5{,}010$

$\Delta kWh_{water_ALL\ OTHERS}$ = $464{,}946/1{,}000{,}000 * 5{,}010$

= $2{,}329\ kWh$

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Past project documentation and data collection is not sufficient to determine summer coincident peak demand savings for this measure. Value should continue to be studied and monitored through additional studies due to limited data points used for this determination. In absence of site-specific data, the summer coincident peak demand savings should be assumed to be zero.

ΔkW = 0

FOSSIL FUEL SAVINGS

$$\Delta Therm = Therm_{Baseline} * \%hot_water_savings$$

Where:

ΔTherm = Gas savings resulting from a reduction in hot water use, in therm.

$Therm_{Baseline}$ = Annual Baseline Gas Consumption

= $WHE * WUtiliz * WUsage_hot$

Where:

WHE = water heating energy: energy required to heat the hot water used

[496] See the "Water Impact Descriptions and Calculation" section of this measure for more information.
[497] See the "Water Impact Descriptions and Calculation" section of this measure for more information.
[498] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

= 0.00885 therm/gallon[499]

WUtiliz = washer utilitzation factor: the annual pounds of clothes washed per year

= actual, if unknown the values below:

Application	WUtiliz
Laundromat	2,190[500] cycles per year * Lbs-Capacity
Hotel/Motel	916,150 lbs[501] (Approx. 4,745 cycles per year) per site
Fitness and Recreation	
Healthcare	
Assisted Living	

WUsage_hot = hot water usage factor: how much hot water a typical conventional washing machine utilizes, normalized per pounds of clothes washed

Application	WUsage_hot
Laundromat	0.64 gallons/lb[502]
Hotel/Motel	1.19 gallons/lb[503]
Fitness and Recreation	
Healthcare	
Assisted Living	

Using defaults above:

$Therm_{Baseline_LAUNDROMAT}$ = 0.00885 * (2,190 cycles per year * Lbs-Capacity) * 0.64

= 12.4 therms * Lbs-Capacity

$Therm_{Baseline_ALL\ OTHERS}$ = 0.00885 * 916,150 * 1.19

= 9648 therms

%hot_water_savings = hot water reduction factor: how much more efficient an ozone injection washing machine is, compared to a typical conventional washing machine, as a rate of hot water reduction

Application	%hot_water_savings
Laundromat	100%
Hotel/Motel	81%[504]
Fitness and Recreation	
Healthcare	

[499] Assuming boiler efficiency is the regulated minimum efficiency (80%), per Title 20 Appliance Standard of the California Energy Regulations (October 2007). The incoming municipal water temperature is assumed to be 55°F with an average hot water supply temperature of 140°F, based on default test procedures on clothes washers set by the Department of Energy's Office of Energy Efficiency and Renewable Energy (Federal Register, Vol. 52, No. 166). Enthalpies for these temperatures (107 btu/lbs at 140°F, 23.07 btu/lbs at 55°F) were obtained from ASHRAE Fundamentals.

[500] DOE Technical Support Document Chapter 6, 2010 https://www.regulations.gov/contentStreamer?documentId=EERE-2006-STD-0127-0118&attachmentNumber=8&disposition=attachment&contentType=pdf

[501] Average utilization factors were generated using data collected from existing ozone laundry projects that received incentives under the NRR-DR program. Table 3 summarizes data gathered from several NRR-DR projects, Nicor Custom projects, and Nicor ETP projects.

[502] Calculated as WUsage * Average % Hot water (estimated at 59% from Custom laundromat data); 1.09*0.59 = 0.64 gal / lbs laundry.

[503] Average hot water usage factors were generated using data collected from existing ozone laundry projects that received incentives under the NRR-DR program. Summarizes data gathered from several NRR-DR projects.

[504] Average hot water reduction factors were generated using data collected from existing ozone laundry projects that received incentives under the Non-Residential Retrofit Demand Reduction program (NRR-DR). Table 5 summarizes data gathered from several NRR-DR projects, Nicor Custom projects, and Nicor ETP projects. Nicor Savings Numbers are associated with ACEE_AWE_Ozone Laundry / From Gas Savings Calculations.

Application	%hot_water_savings
Assisted Living	

Savings using defaults above:

$\Delta Therm = Therm_{Baseline} * \%hot_water_savings$

$\Delta Therm_{LAUNDROMAT} = 12.4 * Lbs - Capacity * 100\%$

$= 12.4\ therms * Lbs - Capacity$

$\Delta Therm_{ALL\ OTHER} = 9648 * 81\%$

$= 7815\ therms\ per\ site$

Default per lb capacity:

$\Delta Therm_{LAUNDROMAT}$ / lb $= 12.4 * Lbs - Capacity\ /\ lb\ capacity$

$= 12.4\ therms\ /\ lb$

$\Delta Therm_{ALL\ OTHER}$ / lb $= 7815\ /\ 254.38$

$= 30.7\ therms\ /\ lb$

WATER IMPACT DESCRIPTIONS AND CALCULATION

The water savings calculations listed here account for the combination of hot and cold water used. Savings calculations for this measure were based on the reduction in total water use from implementing an ozone washing system to the base case. There are three main components in obtaining this value:

$\Delta Water\ (gallons) = WUsage * WUtiliz * \%water_savings$

Where:

ΔWater (gallons) = reduction in total water use from implementing an ozone washing system to the base case

WUsage = water usage factor: amount of total water used by a conventional washing machine normalized per unit of clothes washed

$WUsage_{LAUNDROMATS}$ = 1.09 gallons / lbs laundry[505]

$WUsage_{ALL\ OTHERS}$ = 2.03 gallons/lbs laundry[506]

WUtiliz = washer utilization factor: the annual pounds of clothes washed per year

= actual, if unknown use the values below:

Application	WUtiliz
Laundromat	2,190[507] cycles per year * Lbs-Capacity
Hotel/Motel	916,150 lbs[508] (Approx. 4,745 cycles per year) per site
Fitness and Recreation	
Healthcare	

[505] Based on Peoples Gas custom project data.

[506] Average water usage factors were generated using data collected from existing ozone laundry projects that received incentives under the NRR-DR program. summarizes data gathered from several NRR-DR projects.

[507] DOE Technical Support Document Chapter 6, 2010 https://www.regulations.gov/contentStreamer?documentId=EERE-2006-STD-0127-0118&attachmentNumber=8&disposition=attachment&contentType=pdf

[508] Average utilization factors were generated using data collected from existing ozone laundry projects that received incentives under the NRR-DR program. Table 3 summarizes data gathered from several NRR-DR projects, Nicor Custom projects, and Nicor ETP projects.

Application	WUtiliz
Assisted Living	

%water_savings = water reduction factor: how much more efficient an ozone injection washing machine is compared to a typical conventional washing machine as a rate of hot and cold water reduction.

Application	%water_savings
Laundromat	10%[509]
Hotel/Motel	25%[510]
Fitness and Recreation	
Healthcare	
Assisted Living	

Savings using defaults above:

$\Delta Water = WUsage * WUtiliz * \%water_savings$

$\Delta Water_{LAUNDROMATS} = 1.09 * WUtiliz * 0.1$

$= 1.09 * (2{,}190 * Lbs - Capacity) * 0.1$

$= 239 * Lbs - Capacity$

$\Delta Water_{ALL\ OTHERS} = 2.03 * 916{,}150 * 0.25$

$= 464{,}946\ gallons\ per\ site$

Default per pound:

$\Delta Water_{LAUNDROMATS}$ / lb capacity $= (239 * Lbs - Capacity) / lb - capacity$

$= 239\ gallons/lb$

Δ Water $_{ALL\ OTHERS}$ / lb-capacity $= 464{,}946 / 254.38$

$= 1{,}828\ gallons / lb$

DEEMED O&M COST ADJUSTMENT CALCULATION

Maintenance is required for the following components annually:[511]

- Ozone Generator: filter replacement, check valve replacement, fuse replacement, reaction chamber inspection/cleaning, reaction chamber o-ring replacement
- Air Preparation – Heat Regenerative: replacement of two medias
- Air Preparation – Oxygen Concentrators: filter replacement, pressure relief valve replacement, compressor rebuild
- Venturi Injector: check valve replacement

Maintenance is expected to cost $0.79 / lbs capacity.

[509] Page 7, Laundries and Dry-Cleaning Operations, Watersmart Guidebook EBMUD_WaterSmart_Guide_Laundries_Dry-Cleaning_Operations.pdf.

[510] Average water reduction factors were generated using data collected from existing ozone laundry projects that received incentives under the Non-Residential Retrofit Demand Reduction program (NRR-DR). Table 6 summarizes data gathered from several NRR-DR projects, Nicor Custom projects, and Nicor ETP projects. Nicor Savings Numbers are associated with ACEE_AWE_Ozone Laundry / From Gas Savings Calculations.

[511] Confirmed through communications with national vendors and available references, via an online forum (The Ozone Laundry Blog – The Importance of Maintenance).

MEASURE CODE: CI-HWE-OZLD-V07-230101

REVIEW DEADLINE: 1/1/2030

4.3.7 Multifamily Central Domestic Hot Water Plants

DESCRIPTION

This measure covers multifamily central domestic hot water (DHW) plants with thermal efficiencies greater than or equal to 88%. This measure is applicable to any combination of boilers and storage tanks provided the thermal efficiency of the boiler(s) is greater than 88%. Plants providing other than solely DHW are not applicable to this measure.

This measure was developed to be applicable to the following program types: TOS, NC, ER.

If applied to other program types, the measure savings should be verified.

Note, IECC 2021 has become effective statewide as of January 1, 2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. As code requirements and adoption can differ from municipality to municipality, the user should always verify which version of code is applicable.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify, the boiler(s) must have a Thermal Efficiency of 88% or greater and supply domestic hot water to multi-family buildings.

DEFINITION OF BASELINE EQUIPMENT

For TOS, the baseline boiler is assumed to have a Thermal Efficiency of 80%.[512]

For Early Replacement, the savings are calculated between existing unit and efficient unit consumption during the remaining life of the existing unit, and between new baseline unit as above and efficient unit consumption for the remainder of the measure life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for the domestic hot water boilers is 15 years.[513]

DEEMED MEASURE COST

TOS: The actual install cost should be used for the efficient case, minus the baseline cost assumption provided below:

Capacity Range	Baseline Installed Cost per kBtuh[514]
< 300 kBtuh	$65 per kBtuh
300 – 2500 kBtuh	$38 per kBtuh
> 2500 kBtuh	$32 per kBtuh

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

There are no anticipated electrical savings from this measure.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

Time of Sale:

ΔTherms $= Hot\ Water\ Savings\ +\ Standby\ Loss\ Savings$

$=[(MFHH * \#Units * GPD * Days/yr * \gamma_{Water} * (T_{out} - T_{in}) * (1/Eff_{base} - 1/Eff_{ee})) / 100{,}000] + [((SL * Hours/yr * (1/Eff_{base} - 1/Eff_{ee})) / 100{,}000]$

Early Replacment:[515]

ΔTherms for remaining life of existing unit (first 5 years):

$=[(MFHH * \#Units * GPD * Days/yr * \gamma_{Water} * (T_{out} - T_{in}) * (1/Eff_{exist} - 1/Eff_{ee})) / 100{,}000] + [((SL * Hours/yr * (1/Eff_{exist} - 1/Eff_{ee})) / 100{,}000]$

ΔTherms for remaining measure life (next 10 years):

$=[(MFHH * \#Units * GPD * Days/yr * \gamma_{Water} * (T_{out} - T_{in}) * (1/Eff_{base} - 1/Eff_{ee})) / 100{,}000] + [((SL * Hours/yr * (1/Eff_{base} - 1/Eff_{ee})) / 100{,}000]$

Where:

MFHH = number of people in multifamily household

Household Unit Type	Household[516]		
	IQ Participants	Non-IQ Participants	All Participants
Multifamily - Deemed	2.3	2.09	2.18
Custom	Actual Occupancy or Number of Bedrooms[517]		

#Units = Number of units served by hot water boiler

= Actual

GPD = Gallons of hot water used per person per day

[515] The two equations are provided to show how savings are determined during the initial phase of the measure (existing to efficient) and the remaining phase (new baseline to efficient). In practice, the screening tools used may either require a First Year savings (using the first equation) and then a "number of years to adjustment" and "savings adjustment" input which would be the (new base to efficient savings)/(existing to efficient savings).

[516] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.

[517] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

= Actual. If unknown assume 17.6 gallons per person per day[518]

Days/yr = 365.25

γ_{Water} = Specific Weight of Water

= 8.33 gal/lb

T_{out} = tank temperature of hot water

= 125°F or custom

T_{in} = Incoming water temperature from well or municipal system

= 50.7°F [519]

Eff_{base} = thermal efficiency of base unit

= 80%[520]

Eff_{ee} = thermal efficiency of efficient unit complying with this measure

= Actual. If unknown assume 88%

Eff_{exist} = thermal efficiency of existing unit

= Actual. If unknown assume 73%[521]

SL = Standby Loss[522]

= (Input rating / 800) + (110 * √(Tank Volume)).

Input rating = Name plate input capacity in btuh

Tank Volume = Rated volume of the tank in gallons

Hours/yr = 8766 hours

100,000 = btu/therm

[519] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[520] IECC 2021, Table C404.2, Minimum Performance of Water-Heating Equipment, hot water supply boiler, gas.

[521] Based upon DCEO data provided 10/2014; average age adjusted efficiency of existing units replaced through the program. Efficiency age adjustment of 0.5% per year based upon NREL "Building America Performance Analysis Procedures for Existing Homes".

[522] Stand-by loss is provided in IECC 2012/2015/2018, Table C404.2, Minimum Performance of Water-Heating Equipment.

Time of Sale:

For example, an 88% 1000-gallon boiler with 150,000 btuh input rating installed serving 50 units with average 2.1 people per unit.

ΔTherms $= Hot\ Water\ Savings\ +\ Standby\ Loss\ Savings$

$=[(MFHH * \#Units * GPD * Days/yr * \gamma_{Water} * (T_{out} - T_{in}) * (1/Eff_{base} - 1/Eff_{ee}))\ /\ 100{,}000] + [((SL * Hours/yr * (1/Eff_{base} - 1/Eff_{ee}))\ /\ 100{,}000]$

$= [(2.1 * 50 * 17.6 * 8.33 * 365.25 * 1.0 * (125 - 50.7) * (1/0.8 - 1/0.88))\ /\ 100{,}000] + [((150{,}000/800 + (110 * \sqrt{1000}) * 8766 * (1/0.8 - 1/0.88))\ /\ 100{,}000]$

$= 475 + 37$

$= 512\ therms$

Early Replacement:

For example, an 88% 1000-gallon boiler with 150,000 btuh input rating installed serving 50 units with average 2.1 people per unit replaces a working unit with unknown efficiency.

ΔTherms for remaining life of existing unit first 5 years):

$= [(2.1 * 50 * 17.6 * 8.33 * 365.25 * 1.0 * (125 - 50.7) * (1/0.73 - 1/0.88))\ /\ 100{,}000] + [((150{,}000/800 + (110 * \sqrt{1000}) * 8766 * (1/0.73 - 1/0.88))\ /\ 100{,}000]$

$= 975 + 75$

$= 1050\ therms$

ΔTherms for remaining measure life (next 10 years):

= 475 + 37 (as above)

= 512 therms

4.3.8 Controls for Central Domestic Hot Water

DESCRIPTION

Demand control recirculation pumps seek to reduce inefficiency by combining control via temperature and demand inputs, whereby the controller will not activate the recirculation pump unless both (a) the recirculation loop return water has dropped below a prescribed temperature (e.g., 100°F) and (b) a CDHW demand is sensed as water flow through the CDHW system.

This measure was developed to be applicable to the following program types: TOS, RF, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

There are three efficient technologies to be considered:

- Timer-based: allows the user to program a schedule to perform recirculation during specific windows throughout the day.
- Aquastat-controlled: calls for recirculation when the water temperature at one point in the system falls below a certain pre-programmed setpoint (e.g., 100°F).
- On-Demand: senses the demand as water flow through the CDHW system. These types of system are most adequate on small central water heating systems.

DEFINITION OF BASELINE EQUIPMENT

The baseline for this measure category is existing, uncontrolled recirculation pumps on gas-fired CDHW system.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The effective useful life is 15 years.[523]

DEEMED MEASURE COST

The average cost of the demand controller circulation kit is $1,442 with an installation cost of $768 for a total measure cost of $2,210.[524]

LOADSHAPE

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \Delta kWh_{heater} + \Delta kWh_{pump}$$

ΔkWh_{heater} = $\%ElecDHW * Boiler\ Capacity * (t_{normal\ occ} * R_{normal\ occ} + t_{low\ occ} * R_{low\ occ}) / 3{,}412$

ΔkWh_{pump} = $(HP_{recirc} * 0.746 * (8760 - Pump_{hrs\ controlled}) / Motor_{eff}$

ΔkWh_{pump} = 1,103[525] kWh as default value if values unknown.

Where:

%ElecDHW = proportion of water heating supplied by electric resistance heating

= 1 if electric DHW; 0 if fuel DHW. If unknown, assume 32%[526]

Boiler Capacity = Input Capacity of the Domestic Hot Water boiler in BTU/hr. When paired with the installation of a new boiler, use the actual capacity of the new boiler.

= If the facility uses the same boiler for space heat and domestic hot water, estimate the boiler input capacity for only domestic hot water loads. If this cannot be estimated, use the table below:

Building Type	% of Boiler Input Capacity	Or Use the Following Formulas
Multifamily	22.75%[527]	= 12,493 BTU/hr * (#Apartments) [528]
Dormitories	16.48%[529]	= 4,938 BTU/hr * (#Rooms) [530]
Hotels/Motels	12.33%[531]	= 3,696 BTU/hr * (#Rooms) [532]
Offices	Use Actual Size	Use Actual Size

[525] This value is the average kWh saved per pump based on results from Multi-Family buildings studied in Nicor Gas Emerging Technology Program study, Southern California Gas' study in multiple dormitory buildings, and Minnesota's Evaluation of New DHW System Controls in Hospitality and Commercial Buildings. Note this value does not reflect savings from electric units but electrical savings from gas-fired units. See 'CDHW Controls Summary Calculations.xlsx' for more information.

[526] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024.

[527] This is an average number based on Residential Energy Consumption Survey (2009) data and Commercial Building Energy Consumption Survey (2012) data compiled by U.S. Energy Information Administration, for buildings with more than 5 apartments in Illinois and Nursing Home and Assisted Living facilties in Midwest.

[528] This is based on studies done in multiple university dormitory buildings in the California region, for Southern California Gas' PREPS Program, 2012. It closely matches the design guidelines outlined in 2007 ASHRAE Handbook, Chapter 49: Service Water Heating, Table 7, and assumes 1 to 2 students per dorm room based on typical dorm room layouts. This source provides the source for dormitory assumptions of Boiler Input Capacity, $t_{low\ occ}$, $R_{normal\ occ}$ and $R_{low\ occ}$.

[529] This is based on Commercial Building Energy Consumption Survey (2012) data compiled by U.S. Energy Information Administration, for Education facilities in East North Central.

[530] This is based on studies done at Multi-Family Buildings for the Nicor Gas Emerging Technology Program by Gas Technology Institute. It closely matches the design guidelines outlined in 2007 ASHRAE Handbook, Chapter 49: Service Water Heating, Table 9, and assumes 2.1 persons per apartment as per ComEd PY3 Multi-Family Home Energy Savings Program Evaluation Report Final, May 16, 2012, by Navigant. This source provides the source for dormitory assumptions of Boiler Input Capacity, $t_{low\ occ}$, $R_{normal\ occ}$ and $R_{low\ occ}$.

[531] This value is ratioed upon the Btu per Dwelling per Hotel/Motel vs Dormitory building type assuming the same heating capacity requirements based upon the similarity between the building types.

[532] Calculated based upon ASHRAE 2015 ASHRAE HVAC Applications Table 6 and IL TRM assumptions. See 'CDHW Controls Summary Calculations.xlsx' for more information

$t_{normal\ occ}$ = Total operating hours of domestic hot water burner when the facility has normal occupancy. If unknown, use the following table.

$t_{low\ occ}$ = Total operating hours of domestic hot water burner, when the facility has low occupancy.[533] If unknown, use the following table.

$R_{normal\ occ}$ = Reduction(%) in total operating hours of domestic hot water burner, due to installed central domestic hot water controls, during normal occupancy period. Values are set in the table below.

$R_{low\ occ}$ = Reduction(%) in total operating hours of domestic hot water burner, due to installed central domestic hot water controls, during low occupancy period. Values are set in the table below.

Building Type	$t_{normal\ occ}$ (hours)	$t_{low\ occ}$ (hours)	$R_{normal\ occ}$ (%)	$R_{low\ occ}$ (%)
Multi-Family	2,089[534]	0	24.02%	0%
Dormitories	1,688[535]	520[536]	22.44%	44.57%[537]
Hotels/Motels	2,428[538]	0	13.44%[539]	0%
Offices	2,857[540]	1,231	22.90%	41.70%

$HP_{recirculating}$ = the size of the recirculating pump in HP

0.746 = Conversion factor kW/HP

8760 = Hours of operation of uncontrolled recirculating pump

$Pump_{hrs\ controlled}$ = The table below corresponds to the control types for commercial buildings

Hours of Operation[541]	
Timer	6,570
Aquastat-Controlled	1,095
On Demand	122

$Motor_{eff}$ = The efficiency of the pump motor. Use actual or, if unknown, use the table below:

[533] Low occupancy periods for dormitory buildings can be assumed as vacation day or holiday occupancy.
[534] Based on results of the studies done at Multi-Family Buildings for the Nicor Gas Emerging Technology Program:
Gas Technology Institute. (2014). *1003: Demand-based domestic hot water recirculation Public project report.* Des Plaines, IL: Prepared for Nicor Gas, January 7, 2014.
[535] Based on results of studies performed in multiple university dormitory buildings in the California region, for Southern California Gas' PREPS Program, 2012.
[536] Low occupancy periods for dormitory buildings can be assumed as vacation day or holiday occupancy.
[537] Estimated from low occupancy hours
[538] Calculated from the Btu per dwelling unit and average annual therm consumption for DHW for all Hospitality Buildings noted in "Evaluation of New DHW System Controls in Hospitality and Commercial Buildings", MN Commerce Department Energy Resources, 06/30/2018.
[539] Average Hospitallity Savings, "Evaluation of New DHW System Controls in Hospitality and Commercial Buildings", MN Commerce Department Energy Resources, 06/30/2018.
[540] Based on the report, Energy Efficiency with Domestic Water Heating in Commercial Buildings, ACEEE Summer Study on Energy Efficiency in Buildings, 2010. Using the tables of results for Tuesday, Saturday and Sunday to estimate blended values for $t_{normal\ occ}$, $t_{low\ occ}$, $R_{normal\ occ}$ and $R_{low\ occ}$.
[541] The Hours of operation of recirculating pump for commercial buildings in general from Research and Analysis of the Benefits of Appliance Standards for Domestic Hot Water Circulator Pumps. Energy Solutions (October 2021)

Motor HP	Efficiency
0.25	66.7%
0.33	70.6%
0.5	75.3%
0.75	79.6%
1.0	81.2%
1.5	84.8%
2.0	85.8%
3.0	87.2%

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

Gas savings for this measure can be calculated by using site specific boiler size and boiler usage information or deemed values are provided based on number of rooms for Dormitories and number of apartments for multifamily buildings.[543]

$$\Delta\text{Therms} = \%FossilDHW * Boiler\ Input\ Capacity * (t_{normal\ occ} * Rnormal\ occ + t_{low\ occ} * R_{low\ occ}) / 100{,}000$$

Where:

%FossilDHW = proportion of water heating supplied by fossil fuel heating.

= 0 if electric DHW; 1 if fuel DHW. If unknown, assume 68%[544]

Boiler Input Capacity = Input capacity of the Domestic Hot Water boiler in BTU/hr.

= If the facility uses the same boiler for space heat and domestic hot water, estimate the boiler input capacity for only domestic hot water loads. If this cannot be estimated, use the following table:

[542] Blended efficiencies for small motors IECC 2021, Table C405.8(2), Table C405.8(3) and Table C405.8(3)

[543] See 'CDHW Controls Summary Calculations.xlsx' for more information.

[544] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024.

Building Type	% of Boiler Input Capacity	Or Use the Following Formulas
Multifamily	22.75% [545]	= 12,493 BTU/hr * (#Apartments) [546]
Dormitories	16.48% [547]	= 4,938 BTU/hr * (#Rooms) [548]
Hotels/Motels	12.33% [549]	= 3,696 BTU/hr * (#Rooms) [550]
Offices	Use Actual Size	Use Actual Size

Other variables as provided above.

Based on defaults above:

ΔTherms = 30.1 * number of rooms (for dormitories)

= 62.7 * number of apartments (for multifamily buildings)

= 12.06 * number of rooms (hotels/motels)

For example, a dormitory building has a 400,000 BTU/hr boiler whose burner operates for an estimated 580 hours during vacation months and 1,300 hours during regular occupancy months. Savings from installing central domestic hot water controls in this building are:

ΔTherms = 400,000 BTU/hr * (1,300 * 0.2244 + 580 * 0.4457) / 100,000

= 2,201 therms

4.3.9 Heat Recovery Grease Trap Filter

DESCRIPTION

A heat recovery grease trap filter combines grease filters and a heat exchanger to recover heat leaving kitchen hoods. As a direct replacement for conventional hood mounted filters in commercial kitchens, they are plumbed to the domestic hot water system to provide preheating energy to incoming water.

This measure was developed to be applicable to the following program types: NC and RF. If applied to other program types, the measure savings should be verified. For NC projects, this measure may be applicable if code requirements are otherwise satisfied.

DEFINITION OF EFFICIENT EQUIPMENT

Grease filters with heat exchangers carrying domestic hot water in kitchen exhaust air ducts.

DEFINITION OF BASELINE EQUIPMENT

Kitchen exhaust air duct with constant air flow and no heat recovery.[551]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years.[552]

DEEMED MEASURE COST

Full installation costs, including plumbing materials, labor and any associated controls, should be used for screening purposes.

LOADSHAPE

Loadshape C01 - Commercial Electric Cooking

COINCIDENCE FACTOR

Summer Peak Coincidence Factor for measure is provided below for different building type:[553]

Location	CF
Fast Food Limited Menu	0.32
Fast Food Expanded Menu	0.41
Pizza	0.46
Full Service Limited Menu	0.51
Full Service Expanded Menu	0.36
Cafeteria	0.36
Unknown	0.40

[551] Savings methodology factors are for a constant speed fan.
[552] Professional judgement, consistent with expected lifetime of kitchen demand ventilation controls and other kitchen equipment.
[553]Minnesota 2012 Technical Reference Manual, Electric Food Service_v03.2.xls

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

For electric hot water heaters:

$$\Delta kWh = [(Meal/Day * HW/Meal * Days/Year) * lbs/gal * BTU/lb.°F * (\Delta T/filter * Qty_Filter) * 0.000293] / (\eta_{HeaterElec})$$

Where:

Meal/Day = Average number of meals served per day. If not directly available, see Table 1.

HW/Meal = Hot water required per meal

= 3 gal/meal[554]

Days/Year = Number of days kitchen operates per year. If not directly available, see Table 1.

Lbs/gal = Density of water

= 8.3 lbs/gal

BTU/lb.°F = Specific heat of water

= 1.0

ΔT/filter = Temperature difference of domestic water across each filter

= 5.8°F/filter[555]

Qty_Filter = Number of heat recovery grease trap filters installed. If not directly available, see Table 1.

Commercial Kitchen Load based on Building Type

Building Type	Meals/Day[556]	Assumed days/Year	Number of Filters[557]
Primary School	400	312	2
Secondary School	600	312	3
Quick Service Restaurant	800	312	5
Full Service Restaurant	780	312	4
Large Hotel	780	356	4
Hospital	800	356	4

$\eta_{HeaterElec}$ = Efficiency of the Electric water heater.

= Actual. If unknown, for retrofit use the table C404.2 in IECC 2012. For new construction use the active code at time the permit was issued.

[554] Average dishwashing and faucet water usage taken from Chapter 8, Table 8.3.3 Normalized Annual End Uses of Water in Select Restaurants in Western United States.

REVIEW DEADLINE: 1/1/2027

4.3.10 DHW Boiler and Water Heater Tune-up

DESCRIPTION

Domestic hot water (DHW) boilers and water heaters provide hot water for bathrooms, kitchens, tubs and other appliances. Several commercial and industrial facilities such as multi-family buildings, lodging and restaurants have a separate hot water boiler serving DHW loads. Unlike space heating boilers, DHW boilers operate year round, which means they have a greater need to be properly maintained and tuned up.

This measure calculates savings for tuning up a DHW boiler or water heater to improve its efficiency and reduce its consumption. A boiler or water heater tune-up involves cleaning/inspecting burners, burner nozzles and combustion chambers, adjusting air flow and burner gas input to reduce stack temperatures, and checking venting and safety controls. A pre- and post- tune up combustion efficiency ticket (from combustion analyzer) can be used to confirm the improvement in boiler efficiency.

Boilers that serve only a DHW load are eligible for this measure, as are all types of central gas water heaters (including gas storage and tankless water heaters) for multifamily properties.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the facility must, as applicable, complete the tune-up requirements[560] listed below, by approved technician:

- Measure combustion efficiency using an electronic flue gas analyzer
- Adjust airflow and reduce excessive stack temperatures
- Adjust burner and gas input, manual or motorized draft control
- Check for proper venting
- Complete visual inspection of system piping and insulation
- Check safety controls
- Check adequacy of combustion air intake
- Clean fireside surfaces.
- Inspect all refractory. Patch and wash coat as required.
- Inspect gaskets on front and rear doors and replace as necessary.
- Seal and close front and rear doors properly.
- Clean low and auxiliary low water cut-off controls, then re-install using new gaskets.
- Clean plugs in control piping.
- Remove all hand hole and man hole plates. Flush boiler or water heater with water to remove loose scale and sediment.
- Replace all hand hole and man hole plates with new gaskets.
- Open feedwater tank manway, inspect and clean as required. Replace manway plate with new gasket.
- Clean burner and burner pilot.
- Check pilot electrode and adjust or replace.
- Clean air damper and blower assembly.
- Clean motor starter contacts and check operation.
- Make necessary adjustments to burner for proper combustion.

[560] Act on Energy Commercial Technical Reference Manual No. 2010-4, 9.2.2 Gas Boiler Tune-up.

- Perform all flame safeguard and safety trip checks.
- Check all hand hole plates and man hole plates for leaks at normal operating temperatures and pressures.
- Troubleshoot any boiler system or water heater problems as requested by on-site personnel

DEFINITION OF BASELINE EQUIPMENT

The baseline condition of this measure is a boiler or central water heater for a multifamily property that has not had a tune-up within the past 36 months.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life of this measure is 3 years.[561]

DEEMED MEASURE COST

The cost of this measure is $0.83/MBtu/hr per tune-up.[562]

FOSSIL FUEL SAVINGS

$$\Delta\text{Therms} = ((T_{out} - T_{in}) * HotWaterUse_{Gallon} * \gamma_{water} * 1 * (1/Eff_{before} - 1/Eff_{after}))/100{,}000$$

Where:

T_{OUT}	= Hot water storage tank temperature
	= 125°F
T_{IN}	= Incoming water temperature from well or municipal system
	= 50.7°F [563]
$HotWaterUse_{Gallon}$	= Estimated annual hot water consumption (gallons)
	= Actual if possible to provide reasonable custom estimate. If not, the following methods are provided to develop an estimate:[564]

[561] Act on Energy Commercial Technical Reference Manual No. 2010-4, 9.2.2 Gas Boiler Tune-up.
[562] Work Paper – Tune up for Boilers serving Space Heating and Process Load by Resource Solutions Group, January 2012
[563] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.
[564] Methodology based on Cadmus analysis. Annual hot water usage in gallons based on CBECS (2012) and RECS (2009) consumption data of East North Central (removed outliers of 1,000 kBtuh or less) to calculate hot water usage. Annual hot water gallons per tank size gallons based on the tank sizing methodology found in ASHRAE 2011 HVAC Applications. Chapter 50

1. Consumption per usable storage tank capacity

= Capacity * Consumption/cap

Where:

Capacity = Usable capacity of hot water storage tank in gallons

= Actual

Consumption/cap = Estimate of consumption per gallon of usable tank capacity, based on building type:

Building Type[565]	Consumption/Cap
Convenience	528
Education	568
Grocery	528
Health	788
Large Office	511
Large Retail	528
Lodging	715
Other Commercial	341
Restaurant	622
Small Office	511
Small Retail	528
Warehouse	341
Nursing	672
Multi-Family	894

2. Consumption per unit area by building type

= (Area/1000) * Consumption/1,000 sq.ft.

Where:

Area = Area in sq.ft that is served by DHW boiler or water heater

= Actual

Consumption/1,000 sq.ft. = Estimate of DHW consumption per 1,000 sq.ft. based on building type:

Building Type	Consumption/1,000 sq.ft.
Convenience	4,594
Education	7,285
Grocery	697
Health	24,540
Large Office	1,818
Large Retail	1,354
Lodging	29,548

Service Water Heating. Demand assumptions (gallons per day) for each building type based on ASHRAE Chapter 50 and to LBNL White Paper. LBL-37398 Technology Data Characterizing Water Heating in Commercial Buildings: Application to End Use Forecasting. Assumes hot water heater efficiency of 80%.

[565] According to CBECS 2012 “Lodging” buildings include Dormitories, Hotels, Motel or Inns and other Lodging and “Nursing” buildings include Assisted Living and Nursing Homes.

Building Type	Consumption/1,000 sq.ft.
Other Commercial	3,941
Restaurant	44,439
Small Office	1,540
Small Retail	6,111
Warehouse	1,239
Nursing	30,503
Multi-Family	15,434

3. Consumption by number of people per household

= GPD * Household * 365.25

Where:

GPD = Gallons Per Day of hot water use per person

= 45.5 gallons hot water per day per household / 2.59 people per household.[566]

= 17.6

Household = Average number of people per household

Household Unit Type	Household[567]		
	IQ Participants	Non-IQ Participants	All Participants
Multifamily - Deemed	2.3	2.09	2.18
Custom	Actual Occupancy or Number of Bedrooms[568]		

Use Multifamily if: Building meets utility's definition for multifamily

365.25 = Days per year, on average

γ_{water} = Specific weight capacity of water (lb/gal)

= 8.33 lbs/gal

1 = Specific heat of water (Btu/lb.°F)

Eff_{before} = Efficiency of the boiler or water heater before tune-up

Eff_{after} = Efficiency of the boiler or water heater after tune-up

100,000 = Converts Btu to therms

Note: Contractors should select a mid-level firing rate that appropriately represents the average building operating condition over the course of the year and take readings at a consistent firing rate for pre and post tune-up.

[566] Deoreo, B., and P. Mayer. Residential End Uses of Water Study Update. Forthcoming. ©2015 Water Research Foundation. Reprinted With Permission.

[567] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.

[568] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

For example, tune up of a DHW Boiler heating a 100 gallon storage tank in a nursing home, measuring 80% AFUE prior to tune up and 82.2% AFUE after.

ΔTherms = $((T_{out} - T_{in}) * HotWaterUse_{Gallon} * \gamma_{water} * 1 * (1/Eff_{before} - 1/Eff_{after}))/100{,}000$

= ((125 – 50.7) * (100 * 672) * 8.33 * 1 * (1/0.8 – 1/0.822))/100,000

= 13.9 therms

4.3.11 Tunnel Washers

DESCRIPTION

Laundry equipment can be found at a variety of facilities, including hospitals, hotels, health clubs, penitentiaries, and others. Typically, these facilities use conventional batch washing machines for laundering their linens, towels, napkins and tablecloths, and uniforms. The uniformity of the feedstocks makes them good candidates for conversion to a continuous-batch tunnel washing machine system, which ultimately utilizes less water and detergent than conventional systems. The water savings are ultimately based on a comparison of the water efficiencies between the baseline and efficient equipment (measured in gallons of water per pound of laundry).

DEFINITION OF EFFICIENT EQUIPMENT

A tunnel washing machine utilizes a porous Archimedes screw to move laundry and wash water in opposite (or counterflow) directions. The laundry travels in the upslope direction, while the wash water travels downslope through the holes in the Archimedes screw. The laundry gets progressively cleaner as it travels up the screw, while the wash water gets progressively dirtier as it travels down the screw. The screw can be programmed to intermittently change direction, to provide additional agitation. The mechanical action of the screw and travel path of the wash water through holes helps significantly with the cleaning action of the tunnel washer, allowing a reduction in the amount of detergent and rinse water required.

In contrast to the baseline equipment, the tunnel washer reuses the “rinse” water from the top section of the tunnel into the lower “wash” water sections, along with the gradual introduction of detergent. The continuous counterflow of laundry and wash water ultimately results in a more water-efficient system.

Tunnel washers also utilize automated PLC computer controls to constantly monitor water temperatures in each section of the tunnel and to automate the introduction of fresh water and detergent. The speed of the Archimedes screw can adjust for the varying dirt load of the laundry input. The computer system can typically collect performance data (gallons of water, pounds of detergent, pounds of laundry) over time to continuous evaluate system efficiency.

Tunnel washers can utilize either a hydraulic press extractor to “squeeze” water out of the linen or a more conventional centrifugal extractor that spins the linen to remove the water.

Tunnel washers can also reduce manhours required to process the laundry, as a staff is not required to manually load and unload each batch. The continuous feed of laundry in a tunnel washing machine system requires less labor and reduces the potential for injury from sticking hand and arms into a conventional washing machine drum.

Tunnel washers are quite large compared to conventional washers and require a significant footprint in the facility. In addition, they require approximately 12 feet of ceiling clearance above the top of the tunnel washer for proper installation.

DEFINITION OF BASELINE EQUIPMENT

A traditional batch washing machine has discrete washing and rinsing cycles, wherein the water gets completely drained at the end of each cycle.

Typical top-loading washing machines used in homes and laundromats use approximately 40 gallons of water per load. This equates to 20 gallons for the wash cycle and 20 gallons for the rinse cycle. Some facilities will even utilize a second rinse cycle. The vertical axis design requires enough water in the drum to suspend the fabric in the soapy water.

The next step up in efficiency is a front-loading (or horizontal axis) washing machines. They typically use 20 to 30 gallons of water per load. This equates to 10-15 gallons for the wash cycle and 10-15 gallons for the rinse cycle.

Larger horizontal-axis washing machines can consume up to 45 gallons of water per load, equating to 22 gallons for the wash cycle and 22 gallons for the rinse cycle.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life of this measure is assumed to be 15 years for a new tunnel washing machine.[569]

DEEMED MEASURE COST

The actual cost of the measure should be used.[570]

Algorithm

CALCULATION OF ENERGY SAVINGS

Energy savings from conversion from conventional washing machines to tunnel washing machines are the result of reduced water consumption and reduced natural gas consumption from heating water. There are indirect electric energy savings from reduced potable water treatment and wastewater treatment.

ELECTRIC ENERGY SAVINGS

The electric energy savings are based indirectly on the reduced electricity usage attributed to the water savings from the tunnel washing machine. By applying an "Energy Factor", the water savings (in gallons/year) can be converted to electricity savings (in kWh/year). This "Energy Factor" considers the electric energy requirements of water treatment plants and water distribution infrastructure, and wastewater treatment and distribution infrastructure.

The methodology for estimating water savings is as follows:

$$\Delta Water = [BWME - TWME] \; x \; PLD \; x \; ADPY$$

ΔWater =	Total Water Savings (gallons/year)
BWME =	Baseline Washing Machine Efficiency (gal of water / lb. of laundry)
TWME =	Tunnel Washing Machine Efficiency (gal of water / lb. of laundry)
PLD =	Pounds of Laundry Per Day (lb. laundry/day)
ADPY =	Annual Days Per Year (days/year)

The values for BWME and TWME should be taken from actual equipment specifications or actual measurements (water flow meters and mechanical scales).

Typical values for TWME can be range from 0.75-1.0 gal. of water/lb. of laundry.[571] Some equipment vendors have claimed TWME approaching 0.3-0.4 gal. of water/lb. of laundry.[572] For the purposes of this measure, a TWME value of 0.87 gal. of water/lb. of laundry will be used.

[569] Table 8-18: Average Useful Lifetime of Commercial Washing Equipment, Energy Savings Potential and RD&D Opportunities for Commercial Building Appliances, Navigant Consulting, December 21, 2009.
[570] One study found the average cost of tunnel washers to be $1,100,000. Energy Savings Potential and RD&D Opportunities for Commercial Building Appliances, Navigant Consulting, December 21, 2009. https://www1.eere.energy.gov/buildings/publications/pdfs/corporate/commercial_appliances_report_12-09.pdf
[571] Matt Poe. "Efficient, Flexible Tunnel Washers: Tunnel washers have made leaps forward in technology, productivity in the past 10 years", *American Laundry News,* 12/11/18. <https://americanlaundrynews.com/articles/efficient-flexible-tunnel-washers>
[572] Ibid.

Typical values for BWME can range from 1.8-3.0 gal. of water/lb. of laundry.[573] For the purposes of this measure, a BWME value of 2.03 gal. of water/lb. of laundry will be used.[574]

The PLD is specific to each individual facility. An occupied hotel room typically produces 11 pounds of laundry per day.[575] An occupied hospital bed likely produces a similar amount of laundry load. The laundry loads of restaurants, health clubs, prisons, and other facilities need to be quantified using actual facility data.

The PLD can also be estimated from the Ozone Laundry Measure in the IL TRM, section 4.3.6. This measure gives a Washer Utilization Factor (Wutil) of 916,150 pounds/year of laundry for a typical facility.[576] Assuming 365 days/year of laundry activity, this would give a PLD of 2,508 pounds of laundry per day.

The ADPY is often 365 days per year for facilities that never shut down, including hospitals, hotels, and prisons. Other facilities may have regular shutdown periods, so the ADPY value should be adjusted as necessary.

The electricity savings for this measure can be calculated by applying the energy factor to the ΔWater. This EF considers savings from both potable water treatment and wastewater treatment.

$$\Delta\text{kWhwater} = \Delta Water\ (gallons) \ / \ 1{,}000{,}000 \ * \ Ewater\ total$$

Where

Ewater total = IL Total Water Energy Factor (kWh/Million Gallons)
= 5,010[577]

For example, switching from conventional washing machine technology to tunnel washing machine technology, at a facility that processes the defined 916,150 pounds/year (Wutil) and is open every day of the year.

$\Delta\text{Water} = [BWME \ - \ TWME] \ x \ PLD \ x \ ADPY$
= [(2.03 – 0.87) gal. of water/lb. of laundry] x (916,150 lb. of laundry/year)
= 1,062,734 gal. of water/year

$\Delta\text{kWhwater} = \Delta Water \ / \ 1{,}000{,}000 \ * \ Ewater\ total$
= (1,062,734 gal. of water/year) / 1,000,000 * 5,010 kWh/million gallons
= 5,324 kWh/year

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Since the times of day from the water savings measure do not necessarily coincide with the times of day that the water treatment and distribution equipment is in use, the coincident peak demand savings cannot be determined.

FOSSIL FUEL SAVINGS

With reduced water use by the installation of a tunnel washer, the DHW boiler used to heat the incoming water will use significantly less gas. The below algorithm can be used to calculate natural gas savings for hot water heating.

[573] Theresa Boehl. "Tunnel Washers: The Answer to Rising Labor, Utility Costs?", *American Laundry News,* 5/27/14. <https://americanlaundrynews.com/articles/tunnel-washers>

[576] IL TRM Section 4.3.6 footnote for W_{util}, which states "Average utilization factors were generated using data collected from existing ozone laundry projects that received incentives under the NRR-DR program."
[577] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

$$\Delta\text{Therms} = ((T_{out} - T_{in}) * HotWaterReduction_{Gallon} * \gamma_{water} * 1 * (1/Eff))/100{,}000$$

Where:

T_{OUT}	= Hot water storage tank temperature
	= 125°F
T_{IN}	= Incoming water temperature from well or municipal system
	= 50.7°F [578]
$HotWaterReduction_{Gallon}$	= Estimated annual hot water reduction (gallons)
	= Actual custom estimate
γ_{water}	= Specific weight capacity of water (lb/gal)
	= 8.33 lbs/gal
1	= Specific heat of water (Btu/lb.°F)
Eff	= Efficiency of the boiler
	= Use actual efficiency, otherwise use 80% AFUE
100,000	= Converts Btu to therms

For example, a DHW Boiler with an efficiency of 80% AFUE heats a 100 gallon storage tank in a laundry facility using a tunnel washer. Use of the tunnel washer will save the original laundry site an estimated 1,062,734 gallons of water the below example savings:

$$\Delta\text{Therms} = ((T_{out} - T_{in}) * HotWaterUse_{Gallon} * \gamma_{water} * 1 * (1/Eff))/100{,}000$$

= ((125 – 50.7) * 1,062,734 * 8.33 * 1 * (1/0.8))/100,000

= 8221.8 therms

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

The water savings from the tunnel washing machines will help preserve water supplies, extend the life of water treatment and wastewater treatment plants. The reduction in detergent requirements will also have cost and environmental benefits.

DEEMED O&M COST ADJUSTMENT CALCULATION

Actual O&M cost adjustments should be used for this measure.[579]

4.3.12 Tank Insulation

DESCRIPTION

This measure provides rebates for installation of 1" or 2" fiberglass, mineral fiber, or other types of insulation with similar properties to existing bare heated tanks for industrial and some commercial installations. Storage tanks can hold any heated material including, but not limited to, hot water, thermal oil, chemicals, and asphalt.

Default per square foot savings estimates are provided for both exposed indoor and outdoor storage tanks that are heated by heat transfer fluids including steam and thermal oil. Only systems heated with natural gas are eligible for this measure.

Indoor tanks require at least 1" of insulation and outdoor tanks must have at least 2 inches of insulation and include an all-weather protective jacket. New advanced insulating materials may be thinner and savings can be calculated with 3E Plus v4.1.[580]

This measure was developed to be applicable to the following program types: RF (Retrofit), DI (Direct Install). If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is installing tank insulation to an uninsulated, heated material storage tank. Indoor tanks must have at least 1 inch of insulation (R-value of 2.1) and outdoor tanks must have at least 2" of insulation (R--value of 4.2) and include an all-weather protective jacket.

DEFINITION OF BASELINE EQUIPMENT

The base case for savings estimates is a bare, steel tank. Other tank materials can be used to calculate savings with 3E Plus v4.1. Tanks are not required by mechanical codes to be insulated and are commonly found without any insulation.[581]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 15 years.[582]

INCREMENTAL MEASURE COST

The incremental cost for this measure is $12/ft^2.[583]

$$\Delta\text{Therms} = [ESF_b * A_b + ESF_e * A_e] * Hours * LF * TRF / (100{,}000 * \eta)$$

Where:

ESF_b = Energy savings factor from tank body defined as the difference in heat loss between an insulated condition and a bare condition as found in table below [Btu/hr/ft^2]

A_b = Area of tank body [ft^2]

= Actual

ESF_e = Energy savings factor from tank endcap(s) defined as the difference in heat loss between an insulated condition and a bare condition as found in table below [Btu/hr/ft^2]

A_e = Area of endcap(s) [ft^2]

= Combined area of endcaps if tank is oriented horizontally, separate areas if tank is oriented vertically or only one endcap is insulated

= Actual

Hours = Operating hours of heating system

= Actual

LF = Load factor of heating system

= Annual gas consumption / (Hours * Nameplate Heating Capacity)

TRF = Thermal Regain Factor for tank location and use, see table below. The Custom TRF option may be used on any tank location, including tank locations with deemed TRFs specifically listed in the table below, if supporting justification and calculations for the Custom TRF are provided.

May vary seasonally such as: TRF[summer] * summer hours + TRF[winter] * winter hours where TRF values reflecting summer and winter conditions are apportioned by the hours for those conditions. TRF may also be adjusted by building specific balance point temperature (BPT) and operating hours above and below that BPT.[584]

Tank Location	Assumed Regain	TRF, Thermal Regain Factor
Outdoor	0%	1.0
Indoor, conditioned, annual use (e.g. hot water or process loads), 55°F BPT	45%	0.55
Indoor, semi-conditioned, annual use, 55°F BPT	16%	0.84

[584] Zimmerman, Cliff, Franklin Energy, "Thermal Regain Factor_4-30-14.docx", 2014. Based on climate zone 2. Note 'Location not specified – Commercial' assumes pipes provide DHW year round. 'Location not specified – Commercial' assumes semi-conditioned annual usage.

Tank Location	Assumed Regain	TRF, Thermal Regain Factor
Indoor, unconditioned spaces, (no heat transfer to conditioned space)	0%	1.0
Location not specified - Commercial	45%	0.55
Location not specified – Industrial	16%	0.84
Custom	Custom	1 – assumed regain

100,000 = Conversion factor from BTUs to Therms

η = Efficiency of heating equipment used to heat tanks

= Actual, or if unknown assume 79%[585]

The following table shows conductivities and maximum temperature ratings of similar insulation materials. The average value was used with 3EPlus software to generate the Energy Savings Factors used in the savings algorithm.

Table 1: Insulation Types

Insulation Type	Conductivity (Btu.in/ hr.ft^2.°F @ 300°F)	Max Temp (°F)
Mineral Fiber Pipe and Tank Wrap	0.48	650
Mineral Fiber Board	0.44	850
Polyurethane	0.5	400
Average	0.47	

The tank surface temperature assumption depends on the system type. The following table should be used to select the appropriate Energy Savings Factor based on the fluid temperature:

Table 2: Heating Fluid Temperatures

System Type	Fluid Temperature Assumption (°F)
Low Pressure Steam (< 15 psi)	225
High Pressure Steam (> 60 psi)	315
Thermal Oil	425

The energy savings factors (ESF) were developed using the 3E Plus v4.1 software program, and are derived as the difference in heat loss per square foot of a bare tank and an insulated tank.[586] The energy savings analysis is based on adding 1" (indoor) or 2" (outdoor) thick insulation around bare tanks. Outdoor conditions are assumed to be 48.6°F with a wind speed of 5.0 mph.[587] The thermal conductivity of tank insulation varies by material and temperature rating; to obtain a typical value, a range of materials allowed for this measure was averaged. For insulation materials not in the table above, use 3E Plus v4.1 software to calculate ESF_b and ESF_e.

Energy Savings Factors [Btu/hr/ft^2]

[585] Minimum efficiency for steam boilers as set in IECC 2018 code C403.3.2.

[586] Tank insulation calc_8-4-20.xlsx including tables obtained from 3E Plus v4.1 software.

[587] DOE Weather Data, TMY3 (Typical Meteorological Year), developed by NREL for the average ambient temperature and wind speed for Aurora, IL. Adjusted to align with ASHRAE 24.4 Terrain Category 1 for Large city centers with densely populated, tall buildings (2017).

		Low Pressure Steam	High Pressure Steam	Thermal Oil
Vertical Tank - Body	Indoor	290.2	559.0	991.8
	Outdoor	373.4	666.0	1132.0
Horizontal Tank - Body	Indoor	290.2	559.0	991.8
	Outdoor	373.4	666.0	1132.0
Vertical Tank End - Top	Indoor	336.8	642.8	783.9
	Outdoor	426.3	756.2	1269.6
Vertical Tank End - Bottom	Indoor	189.8	380.0	712.1
	Outdoor	288.1	515.7	897.3
Horizontal Tank End	Indoor	290.2	559.0	991.8
	Outdoor	373.4	666.0	1132.0

For example, an outdoor, vertical, cylindrical tank with a radius of 5 ft and height of 15 ft heated by a thermal oil heating system that is insulated around the body and top of the tank would save (assuming 4380 hours of operation, 70% load factor, and 78% efficient thermal oil heater):

ΔTherms $=[ESF_b * A_b + ESF_e * A_e] * Hours * LF * TRF / (100{,}000 * \eta)$

ESF_b = 1132.0 Btu/hr/ft^2

A_b = 2 * π * r * h

= 471.2 ft^2

ESF_e = 1269.6 Btu/hr/ft^2

A_e = π * r^2

= 78.5 ft^2

Hours = 4380

LF = 0.7

TRF = 1.0

η = 0.78

ΔTherms = [1132.0 * 471.2 + 1269.6 * 78.5] * 4380 * 0.7 * 1 / (100,000 * 0.78)

= 24,884 therms

4.3.13 Tankless Water Heater Array

DESCRIPTION

A Central Condensing Tankless Water Heater (CCTWH) array is a type of domestic hot water heating system formed by integrating multiple condensing tankless water heating units in a modular style to increase overall system capacity, turndown capability and to reduce standby energy losses. Hot water energy savings resulting from reduction in standby losses and improved system efficiency are detailed in this measure.

Traditional domestic water heaters for large commercial applications come in two basic designs: conventional tank type water heaters and boilers with external storage tanks. Both these systems produce large volumes of hot water even when there is no demand, resulting in significant standby energy losses. For facilities with peak domestic hot water loads, the water heating system will be sized and installed to meet peak hot water loads. These large systems will often have low turndown ratios and will result in lower efficiencies during lower hot water loads.

On the other hand, gas fired instantaneous or tankless water heaters are defined by code for federal regulations[588] as water heaters which produce not less than 4,000 Btu/hr per gallon of storage. Multiple individual condensing gas fired tankless water heating units are integrated together with specific system controls to form a CCTWH array.

As a replacement to conventional central domestic hot water systems, CCTWH arrays primarily yield energy savings by minimizing standby heat losses and providing high turn-down ratios and there by maximizing the "condensing" efficiency of the water heating system. The temperature difference between supply water temperature and inlet water temperature of the water heater determines the efficiency if the water heater. The inlet/return water temperatures need to be lower to achieve higher efficiencies. Without a storage tank, CCTWH arrays have lower thermal mass and lower return water temperatures to achieve high condensing level efficiencies. Typical points of application of CCTWH array are building types with high peak water heating demands and high turn down ratios like Multifamily, Hotels/ Motels, Hospitals and Universities/ Schools.

This measure involves estimation of hot water energy savings for multiple varying building specific and system specific parameter inputs to estimate hot water usage and energy savings. An external spreadsheet calculator[589] located at [link] has been developed which utilizes the following inputs to facilitate the estimation of the hot energy savings for this measure.

- Measure type (New construction NC or Time of sale TOS)
- Building type[590]
    - Application type: Multifamily, Hotels and Motels.
        - Number of units served by the water heater.
    - Application type: Hospital and Healthcare buildings
        - Number of beds in the spaces served by the water heater.
    - Application type: Offices, Schools, and Universities.
        - Daily occupancy in the spaces served by the water heater.
    - Application type: Other Commercial buildings.
        - Gross building floor area served by the water heater.
- Climate Zone: Rockford, Chicago, Springfield, Belleville, Marion
- Baseline water heater type, firing rate, storage volume and rated stand by loss for measure type Time of sale (TOS).
- CCTWH array firing rate, storage volume, peak flow rate at 70°F ΔT and rated standby loss.

This measure was developed to be applicable to the following program types: NC and TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Central Condensing Tankless Water Heater array (CCTWH array) are formed by integrating individual gas fired condensing tankless water heating units into a modular system with specific system controls. Gas fired Instantaneous or Tankless water heaters shall produce not less than 4,000 Btu/hr per gallon of storage as defined by federal code for regulations[591]. CCTWH array system to be used as part of this measure should be greater than 200,000 Btu/hr

[588]Gas fired Instantaneous water heater as defined in code for federal regulations. eCFR :: 10 CFR Part 431 Subpart G -- Commercial Water Heaters, Hot Water Supply Boilers and Unfired Hot Water Storage Tanks

[589] Externally attached spreadsheet tool 'Energy Savings Calculator for Central Condensing Tankless Water Heater Array.xlsm'.

[590] Building type definitions are as defined in Illinois Technical Reference Manual version 11, Volume 1: Overview and User Guide, Section 3.6 Glossary. IL-TRM_Effective_010123_v11.0_Vol_1_Overview_09222022_FINAL.pdf (ilsag.info)

[591] Gas fired Instantaneous water heater as defined in code for federal regulations. eCFR :: 10 CFR Part 431 Subpart G -- Commercial Water Heaters, Hot Water Supply Boilers and Unfired Hot Water Storage Tanks

and produce not less than 4,000 Btu/hr per gallon of stored water. CCTWH array system as a part of the measure shall have a rated thermal efficiency greater than 90%.

DEFINITION OF BASELINE EQUIPMENT

Time of Sale: This measure type is only applicable for existing commercial gas fired water heaters being replaced after the end of their useful life. The baseline condition is assumed to be a new standard water heater of same type as the existing unit being replaced. The efficiency of the baseline water heater in this case, would be or minimum efficiency as required by the federal standards[592]. If existing equipment type is unknown, the baseline condition is assumed to be a standard commercial gas fired storage type water heater meeting federal minimal efficiency standards listed in table below.

New Construction: The baseline condition is assumed to be a new standard commercial gas fired storage type water heater meeting federal minimum efficiency standards listed in table below.

Equipment Type[593]	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor
Commercial Gas Storage Water Heaters (Including Storage water heaters and Service hot water boilers with external storage tanks)	>75,000 Btu/hr	All	80% $E_{thermal}$, Btu/hr Standby Losses = (Q /800 + 110√Rated Storage Volume in Gallons), Btu/hr
Commercial Gas Instantaneous Water Heaters	<10 gal and >200,000 Btu/hr	All	80% $E_{thermal}$, Btu/hr Standby Losses = NA
	≥10 gal and >200,000 Btu/hr	All	80% $E_{thermal}$, Btu/hr Standby Losses = (Q /800 + 110√Rated Storage Volume in Gallons), Btu/hr

For the purpose of calculating baseline water heater standby losses in measure type NC, Capacity of the Baseline water heater (NC) is calculated as follows:

(NC)Baseline water heater capacity (Btu/hr) = Recovery demand * ΔT * 8.33/ŋ

Recovery demand (gph)	= Peak flow (gpm) * 30
Peak flow (gpm)	= Peak flow of the CCTWH array at 70 °F ΔT temperature rise.
30	= A peak flow of 30 minutes is assumed to estimate peak gallons per hour recovery demand.
8.33	= 8.33 lb/gal of water
ŋ	= 0.8 (Efficiency of the (NC) Baseline water heater)
(NC) Baseline water heater storage (Gal)	= (NC) Baseline water heater capacity (Btu/hr) /3,999

[592] Residential-Duty and Commercial Federal Standard are from DOE Standard 10 CFR 431. eCFR :: 10 CFR Part 431 Subpart G -- Commercial Water Heaters, Hot Water Supply Boilers and Unfired Hot Water Storage Tanks

[593] Commercial Water heater equipment type definitions are per U.S Department of Energy, federal code for regulation standards.

3,999	= Conversion factor to estimate minimum storage volume to be defined as a storage type water heater per U.S. federal code for standards.

Note that (NC) Baseline water heater capacity and (NC) Baseline water heater storage are only utilized to calculate baseline system standby loss for calculating measure energy savings.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years[594].

DEEMED MEASURE COST

Actual costs should be used where available. Total equipment cost assumptions for the measure can used from table below if actual costs are unknown. Depending on actual site demand requirements, CCTWH array is expected to have higher firing rate than a storage water heater, to meet the same hot water demand. While computing incremental costs for this measure, corresponding firing rates shall be utilized for the Baseline water heater and the CCTWH array.

Capacity	Total Equipment Cost- CCTWH Array	Total Equipment Cost Baseline[595]	
		Storage Type Water Heater	Service Hot Water Boiler with Storage Tanks
≤800 kBtu/hr	14.45 $/kBtu/hr[596]	34.67 $/kBtu/hr	27.50 $/kBtu/hr
>800 kBtu/hr	31.21 $/kBtu/hr[597]		

Incremental Cost	= (Unit Cost CCTWH Array * Eff firing rate) – (Unit Cost Baseline * Baseline firing rate)
Unit Cost	= Cost per firing rate of the water heating equipment ($/kBtu/hr).
Eff firing rate	= Firing rate(kBtu/hr) of the Central condensing tankless water heater array.
Baseline firing rate	= Firing rate(kBtu/hr) of the Baseline domestic water heater.

For baseline water heater firing rate in measure type NC, refer to Definition of baseline equipment section.

[594] California ETRM, Tankless water heater commercial measure (Version SWWH006-07) lists a useful life of 20 years. California Public Utilities Commission (CPUC), Energy Division. 2014. "DEER2014-EUL-table-update_2014-02-05.xlsx." https://www.caetrm.com/login/?next=/measure/SWWH006/07/

[595] Baseline install costs are based on data from 2010-2012_WO017_Ex_Ante_Measure_Cost_Study_-_Final_Report.pdf (calmac.org) . Only equipment and miscellaneous costs are considered excluding labor costs for a non-condensing 82% TE storage type water heater. Average of equipment and miscellaneous costs for Large storage water heater Et=80% and SHW Boilers Et=82% are used to estimate equipment cost per kBtu/hr.

[596] Install cost from Swierczyna, R., P. Glanville, M. Mensinger Jr., A. Haynor, B. Schoenbauer. 2022. Demonstration of Packaged Central Condensing Tankless Water Heating Systems in Multifamily Buildings. Minnesota Commerce Department. https://mn.gov/commerce/energy/conserving-energy/applied-research-development/

[597] Install cost for CCTWH array greater than 800 kBtu/hr are from GTI Energy field demonstration projects in Illinois.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

There are no anticipated electrical energy savings for this measure.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

$$\Delta Therms = \{[G \; x \; 8.33 \; x \; 1 \; x \; (Tout - Tin) \; x \; ((1/\eta base) - (1/\eta eff))] + (SLbase - SLeff)\} / 1{,}000{,}00$$

Where:

G = Annual hot water use (in gallons).

= Actual annual hot water usage (If hot water usage is metered in measure type TOS)

= Average daily hot water use x Operating days in a year. (if daily use is listed in table below.

Operating days in a year = Actual or If unknown, use values from table below.

Building Type[598] [599]	Operating Days per Year
Offices	250
Restaurant	365
Retail	365
Grocery stores/ Convenience stores	365
Warehouses	250
Schools	200
Universities	200
Health	365
Hotels, Motels	365
Multifamily	365
Other Commercial	250

Average daily hot water use to be calculated from table below based on building type.

Building Type	Consumption	Unit
Multi-family	36.9	Gal/unit/day[600]
Hotels <=20 units	20	Gal/unit/day[601]

Hotels 21-99 Units	14	Gal/unit/day
Hotels 100+ units	10	Gal/unit/day
School (Jr/Sr High)	1.8	Gal/student/day
Elementary school	0.6	Gal/student/day
Universities	1.8	Gal/person/day
Hospitals	18.4	Gal/bed/day
Office	1	Gal/person/day
Retail >=30,000 SF	1,354	Gal/1000 SF/year[602]
Retail < 30,000 SF	6,111	Gal/1000 SF/year
Restaurants	44,439	Gal/1000 SF/year
Grocery store	697	Gal/1000 SF/year
Convenience	4,594	Gal/1000 SF/year
Warehouse	1,239	Gal/1000 SF/year
Other Commercial	3,941	Gal/1000 SF/year

8.33 = Density of water lb/gal.

1 = Specific heat capacity of water Btu/lb ^{o}F.

Tout = water heater set point (^{o}F) (demand temperature) is assumed to be 125 ^{o}F. If custom higher water temperatures are used, actual tank water temperature should be verified.

Tin = Average inlet water temperature (^{o}F) is based on the building location nearest to zones listed in table below.

Typical Entering Cold-Water Temperatures[603] in ^{o}F			
Zones	**Min**	**Avg**	**Max**
(1)Rockford	40.86	53.80	66.31
(2)Chicago O'Hare	44.10	56.17	67.85
(3)Springfield	46.05	59.38	72.30
(4)Belleville	48.24	60.08	71.55
(5)Marion	49.63	62.09	74.19

ηbase = Rated efficiency of baseline water heater in Thermal efficiency (Et) can be actual value if known or can be taken from per table in definition of baseline equipment.

ηnew = Rated efficiency of the efficient CCTWH array in Thermal efficiency (Et).

SLbase = Annual Standby energy loss of the baseline water heater in btu.

= SL rated base X H

SL rated base = Rated Standby loss rating of the baseline water heater in Btu/hr.

= Actual or if unknown, Use calculation below to estimate standby losses.

= (Q /800 + 110√Rated Storage Volume in Gallons), Btu/hr

[602] 2022 IL Technical reference manual, version 11, volume 2, section 4.3.1., lists consumption/ cap for retail spaces, restaurants, grocery stores, convenience stores, Warehouses and other commercial spaces. Update with reference from 4.3.1

[603] Cold water temperatures are taken From US DOE, Building America Analysis Spreadsheets

Q = Capacity/ Firing rate of the Baseline water heater in Btu/hr

H = 8760 annual hours of operation is assumed for estimating stand by losses.

SLeff = Annual Standby energy loss of the efficient CCTWH array in btu.

= SL rated eff X H

SL rated eff = Rated Standby loss rating of the efficient CCTWH array in Btu/hr

= or Actual Standby loss rating values based on CCTWH system operation. This will need to be verified to be utilized in the measure.

=If unknown and CCTWH array rated storage volume is greater than or equal to 10 gallons, assume a standby loss of,

Qeff /800 + 110√Rated Storage Volume in Gallons), Btu/hr

Qeff = Capacity/ Firing rate of the CCTWH array in Btu/hr.

For example, savings for a CCTWH array with 796 kbtu/hr input rating, 20 gpm peak flow at 70 ^{o}F ΔT and 96% TE is installed serving 23 units in a multi-family building in Chicago, replacing a storage type water heater 199 kBtu/hr input rating, 100-gallon storage and 80% TE, is calculated as follows:

Following inputs listed below shall be utilized to estimate Therms savings in the external spreadsheet calculator.

Description	Input	Calculated Annual Therms Savings
Measure type	Time of Sale (TOS)	489 Therms
Building Type	Multi-family	
Number of units served by the water heater	23	
Building location: Climate Zone	Climate Zone2: Chicago	
Baseline water heater type	Commercial gas fired storage water heater	
Baseline water heater Firing rate input	199 kBtu/hr	
Baseline water heater storage capacity	100 Gallons	
CCTWH array system firing rate input	796 kBtu/hr	
CCTWH array system Thermal efficiency	96%	

The same example; when a CCTWH array with 796 kbtu/hr input rating, 20 gpm peak flow at 70 °F ΔT and 96% TE is installed serving 23 units in a multi-family building in Chicago is installed in New Construction, Hot water energy savings are estimated as based on input listed below.

Description	Input	Calculated Annual Therms Savings
Measure type	New Construction (NC)	518 Therms
Building Type	Multi-family	
Number of units served by the water heater	23	
Building location: Climate Zone	Climate Zone2: Chicago	
Baseline water heater type	Commercial gas fired storage water heater	
CCTWH array system firing rate input	796 kBtu/hr	
CCTWH array system Thermal efficiency	96%	
CCTWH array system Peak flow at 70 °F temperature rise	20 gpm

REVIEW DEADLINE: 1/1/2029

4.4. HVAC End Use

Many of the commercial HVAC measures use equivalent full load hours (EFLH) to calculate heating and cooling savings. The tables with these values are included in this section and referenced in each measure.

To calculate the updated EFLHs by building type and climate zone provided below, most of the eQuest models that were previously developed by a TAC Subcommittee utilizing building energy models originally developed for ComEd[604], were migrated to OpenStudio by a parametric calibration process. The parametric runs were controlled with a genetic learning algorithm to characteristically adjust the seed models to achieve an acceptable target error against the existing eQuest model population. The breadth of the characteristic variations was informed through a sensitivity analysis, the IL joint assessment survey, and the existing eQuest models. The DOE prototypical models served as the initial seed model for most instances of calibration except where a direct map to available prototypes was unavailable.

The building characteristics of the eQuest models can be found in the reference table named "EFLH Building Descriptions Updated 2014-11-21.xlsx". The OpenStudio models are based upon the DOE Prototypes described in NREL's "U.S. Department of Energy Commercial Reference Building Models of the National Building Stock" and a calibration log file that documents all of the variations made to each model to get them calibrated is provided in "IL-Calibration-Log_2019-08-27.xlsx". These documents and all the models are all available on the SharePoint site.

Note, for greenhouse boiler control measures, like Modulating Boiler Controls and/or Boiler Oxygen Trim Controls it is recommended to use methodology detailed in 4.4.21 Linkageless Boiler Controls for Space Heating and 4.4.22 Oxygen Trim Controls for Space Heating Boilers, respectively.

Note where a measure installation is within a building or application that does not fit with any of the defined building types below, the user should apply custom assumptions where it is reasonable to estimate them, else the building of best fit should be utilized.

4.4.1 Air Conditioner Tune-up

DESCRIPTION

An air conditioning system that is operating as designed saves energy and provides adequate cooling and comfort to the conditioned space

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be a unitary or split system air conditioner at least 3 tons and preapproved by program. The measure requires that a certified technician performs the following items:

- Check refrigerant charge
- Identify and repair leaks if refrigerant charge is low
- Measure and record refrigerant pressures
- Measure and record temperature drop at indoor coil
- Clean condensate drain line
- Clean outdoor coil and straighten fins
- Clean indoor and outdoor fan blades
- Clean indoor coil with spray-on cleaner and straighten fins
- Repair damaged insulation – suction line
- Change air filter
- Measure and record blower amp draw

A copy of contractor invoices that detail the work performed to identify tune-up items, as well as additional labor and parts to improve/repair air conditioner performance must be submitted to the program.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline condition is assumed to be an AC system that that does not have a standing maintenance contract or a tune up within in the past 36 months.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 3 years.[608]

DEEMED MEASURE COST

Tune-up costs can vary considerably, particularly if refrigerant leak detection, remediation and recharge is necessary. Actual invoiced tune-up costs should be used.

LOADSHAPE

Loadshape C03 - Commercial Cooling

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [609]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

[608] 3 years is given for "Clean Condenser Coils – Commercial" and "Clean Evaporator Coils". DEER2014 EUL Table.
[609] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

= 47.8%[610]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWH = (kBtu/hr) * [(1/EERbefore) - (1/EERafter)] * EFLH$$

Where:

kBtu/hr = capacity of the cooling equipment actually installed in kBtu per hour (1 ton of cooling capacity equals 12 kBtu/hr).

=Actual

EERbefore = Energy Efficiency Ratio of the baseline equipment prior to tune-up[611]

=Actual

EERafter = Energy Efficiency Ratio of the baseline equipment after to tune-up

=Actual

EFLH = Equivalent Full Load Hours for cooling in Existing Buildings are provided in section 4.4 HVAC End Use

Where it is not possible or appropriate to perform Test in and Test out of the equipment, the following deemed methdology can be used:

$$\Delta kWh = (kBtu/hr) \,/\, EERbefore * EFLH * \%Savings$$

Where:

%Savings = Deemed percent savings per Tune-Up component. These are additive if condenser cleaning, evaporator cleaning and refrigerant charge correction are performed (totals provided below)[612]

Tune-Up Component	% Savings
Condenser Cleaning	6.10%
Evaporator Cleaning	0.22%
Refrig. Charge Off. <=20%	0.68%
Refrig. Charge Off. >20%	8.44%

[610]Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[611] In the context of this measure Energy Efficiency Ratio (EER) refers to field-measured steady-state rate of heat energy removal (e.g., cooling capacity) by the equipment in Btuh divided by the steady-state rate of energy input to the equipment in watts. This ratio is expressed in Btuh per watt (Btuh/watt). The cooling capacity may be derived using either refrigerant or air-side measurements. The measurement is performed at the outdoor and indoor environmental conditions that are present at the time the tune-up is being performed, and should be normalized using a correction function to the AHRI 210/240 Standard test conditions. The correction function should be developed based on manufacturer's performance data. Care must be taken to ensure the unit is fully loaded and operating at or near steady-state. Generally, this requires that the outside air temperature is at least 60°F, and that the unit runs with all stages of cooling enabled for 10 to 15 minutes prior to making measurements. For more information, please see "IL TRM_Normalizing to AHRI Conditions Method".

[612] Savings estimates are determined by applying the findings from DNV-GL "Impact Evaluation of 2013-2014 HVAC3 Commercial Quality Maintenance Programs", April 2016, to simulate the inefficient condition within select eQuest models and across climate zones. The percent savings were consistent enough across building types and climate zones that it was determined appropriate to apply a single set of assumptions for all. See 'eQuest C&I Tune up Analysis.xlsx' for more information.

Tune-Up Component	% Savings
Combined (Refrig. Charge Off. <=20%)	7.00%
Combined (Refrig. Charge Off. >20%)	14.76%

For example, a 12 EER 5-ton rooftop air conditioner on a department store in Rockford receives a tune-up that includes both condenser and evaporator cleaning:

ΔkWh = (5*12) / 12 * 1,392 * 6.32%

= 440 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW_{SSP} = (kBtu/hr * (1/EERbefore - 1/EERafter)) * CF_{SSP}$$

$$\Delta kW_{PJM} = (kBtu/hr * (1/EERbefore - 1/EERafter)) * CF_{PJM}$$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [613]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [614]

Where it is not possible or appropriate to perform Test in and Test out of the equipment, the following deemed methdology can be used:

$$\Delta kW = (kBtu/hr) / EERbefore * \%Savings * CF$$

4.4.2 Space Heating Boiler Tune-up

DESCRIPTION

This measure is for a non-residential boiler that provides space heating. The tune-up will improve boiler efficiency by cleaning and/or inspecting burners, combustion chamber, and burner nozzles. Adjust air flow and reduce excessive stack temperatures, adjust burner and gas input. Check venting, safety controls, and adequacy of combustion air intake. Combustion efficiency should be measured before and after tune-up using an electronic flue gas analyzer.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the facility must, as applicable, complete the tune-up requirements listed below[615] by approved technician:

- Measure combustion efficiency using an electronic flue gas analyzer
- Adjust airflow and reduce excessive stack temperatures
- Adjust burner and gas input, manual or motorized draft control
- Check for proper venting
- Complete visual inspection of system piping and insulation
- Check safety controls
- Check adequacy of combustion air intake
- Clean fireside surfaces.
- Inspect all refractory. Patch and wash coat as required.*
- Inspect gaskets on front and rear doors and replace as necessary.*
- Seal and close front and rear doors properly.*
- Clean low and auxiliary low water cut-off controls, then re-install using new gaskets.*
- Clean plugs in control piping.*
- Remove all hand hole and manhole plates. Flush boiler with water to remove loose scale and sediment.*
- Replace all hand hole and manhole plates with new gaskets.*
- Open feedwater tank manway, inspect and clean as required. Replace manway plate with new gasket.*
- Clean burner and burner pilot.
- Check pilot electrode and adjust or replace.
- Clean air damper and blower assembly.
- Clean motor starter contacts and check operation.*
- Make necessary adjustments to burner for proper combustion.
- Perform all flame safeguard and safety trip checks.
- Check all hand hole plates and manhole plates for leaks at normal operating temperatures and pressures.
- Troubleshoot any boiler system problems as requested by on-site personnel

Note: Tune-up activities marked with an asterisk (*) are eligible to be performed by internal maintenance staff at periods of boiler shutdown.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition of this measure is a boiler that has not had a tune-up within the past 36 months.

[615] Act on Energy Commercial Technical Reference Manual No. 2010-4, 9.2.2 Gas Boiler Tune-up

4.4.3 Process Boiler Tune-up

DESCRIPTION

This measure is for a non-residential boiler for process loads. For space heating, see measure 4.4.2. The tune-up will improve boiler efficiency by cleaning and/or inspecting burners, combustion chamber, and burner nozzles. Adjust air flow and reduce excessive stack temperatures, adjust burner and gas input. Check venting, safety controls, and adequacy of combustion air intake. Combustion efficiency should be measured before and after tune-up using an electronic flue gas analyzer.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the facility must, as applicable, complete the tune-up requirements by approved technician[620] as specified below:

- Measure combustion efficiency using an electronic flue gas analyzer
- Adjust airflow and reduce excessive stack temperatures
- Adjust burner and gas input, manual or motorized draft control
- Check for proper venting
- Complete visual inspection of system piping and insulation
- Check safety controls
- Check adequacy of combustion air intake
- Clean fireside surfaces
- Inspect all refractory. Patch and wash coat as required.*
- Inspect gaskets on front and rear doors and replace as necessary.*
- Seal and close front and rear doors properly.*
- Clean low and auxiliary low water cut-off controls, then re-install using new gaskets.*
- Clean plugs in control piping.*
- Remove all hand hole and man hole plates. Flush boiler with water to remove loose scale and sediment.*
- Replace all hand hole and man hole plates with new gaskets.*
- Open feedwater tank manway, inspect and clean as required. Replace manway plate with new gasket.*
- Clean burner and burner pilot.
- Check pilot electrode and adjust or replace.
- Clean air damper and blower assembly.
- Clean motor starter contacts and check operation.*
- Make necessary adjustments to burner for proper combustion.
- Perform all flame safeguard and safety trip checks.
- Check all hand hole plates and man hole plates for leaks at normal operating temperatures and pressures.
- Troubleshoot any boiler system problems as requested by on-site personnel

Note: Tune-up activities marked with an asterisk (*) are eligible to be performed by internal maintenance staff at periods of boiler shutdown.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition of this measure is a boiler that has not had a tune-up within the past 24 months and that does not have a standing maintenance contract.

4.4.4 Boiler Lockout/Reset Controls

DESCRIPTION

This measure relates to improving combustion efficiency by adding controls to non-residential space heating boilers to vary the boiler entering water temperature relative to heating load as a function of the outdoor air temperature to save energy. Energy is saved by increasing the temperature difference between the water temperature entering the boiler in the boiler's heat exchanger and the boiler's burner flame temperature. The flame temperature remains the same while the water temperature leaving the boiler decreases with the decrease in heating load due to an increase in outside air temperature. A lockout temperature is also set to prevent the boiler from turning on when it is above a certain temperature outdoors.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Natural gas customer adding boiler reset controls capable of resetting the boiler supply water temperature in an inverse linear fashion with outdoor air temperature. Boiler lockout temperatures should be set to 55 °F at this time as well, to turn the boiler off when the temperature goes above a certain setpoint.

DEFINITION OF BASELINE EQUIPMENT

Existing boiler without boiler reset controls, any size with constant hot water flow.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life of this measure is 16 years.[626]

DEEMED MEASURE COST

The cost of this measure is $612.[627]

[628] Savings factor is the estimate of annual gas consumption that is saved due to adding boiler reset controls. A comparable savings factor, based on boiler tuneup savings is derived from Xcel Energy "DSM Biennial Plan-Technical Assumptions," Colorado. For further substantiation, Wisconsin Focus on Energy 2020 TRM uses 8%, citing multiple sources. And other prescriptive programs across the country consistently use between 5 and 10% savings factor (Efficiency Vermont - 2020, New York TRM, version 7.0 – 2020 (Cadmus Group, Inc. Home Energy Services Impact Evaluation, August 2012, pg. 20)).

4.4.5 Condensing Unit Heaters

DESCRIPTION

This measure applies to a gas fired condensing unit heater installed in a commercial application.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be a condensing unit heater up to 300 MBH with a Thermal Efficiency > 90% and the heater must be vented, and condensate drained per manufacturer specifications. The unit must be replacing existing natural gas equipment.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline condition is assumed to be a non-condensing natural gas unit heater at end of life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years.[629]

DEEMED MEASURE COST

The incremental capital cost for a unit heater is equal to the input capacity in kBtu/h multiplied by $15.56[630]

Incremental cost = Capacity * $15.56

Where:

Capacity	= Nominal rating of the input capacity of the new condensing unit heater in kBtu/hr
$15.56	= Incremental cost per kBtu/h of input capacity of a new condensing unit heater

LOADSHAPE

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

N/A

[629]DEER 2008

[630]The incremental capitol cost is based on historic project data from Wisconsin Focus on Energy, spanning 2015 through June 2018. The data is aggregated based on 29 projects that comprised of 100 installed unit heaters. The average installed unit heater cost was $22.64 / kBtu/h of input unit capacity. The baseline unit heater cost was estimated to be $7.08 / kBtu/h of input unit capacity, per review of online pricing of Reznor and Modine models on Supply House's website. The incremental cost was sourced from the 2020 Wisconsin Focus on Energy TRM, Public Service Commission of Wisconsin, Cadmus – "Unit Heaters, > 90% Thermal Efficiency (pg. 234)

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

$$\Delta\text{Therms} = ((Capacity * EFLH * UF) / 100) * (1 / Eff_{Base} - 1 / Eff_{EE})$$

Where:

Capacity = Nominal rating of the input capacity of the new condensing unit heater in kBtu/hr

= Actual

UF = Utilization Factor

= 72.5%,[631] or custom

Eff_{Base} = Combustion Efficiency of the baseline unit heater

= Default value is 80%[632]

Eff_{EE} = Combustion Efficiency of the installed unit heater

= Actual. Default value is 90%

100 =converstion from kBtu to therms

EFLH = Equivalent Full Load Hours for in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

For example, a 150 kBtu condensing unit heater with a combustion efficiency of 90% is installed in a garage in Rockford:

Δtherms =((150 * 985 * 0.725) / 100) * (1 / 0.80 – 1 / 0.90)

= 149 therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

MEASURE CODE: CI-HVC-CUHT-V03-230101

REVIEW DEADLINE: 1/1/2027

[631] The utilization factor accounts for the fact that unit heaters are typically over-sized. Value as sourced from the 2020 Wisconsin Focus on Energy Technical Reference Manual, Public Service Commission of Wisconsin, Cadmus – Unit Heaters, ≥ 90% Thermal Efficiency (pg. 234)

[632] Baseline combustion efficiency is sourced from IECC 2021 for all capacity warm-air unit heaters, gas-fired.

4.4.6 Electric Chiller

DESCRIPTION

This measure relates to the installation of a new electric chiller meeting the efficiency standards presented below. This measure could relate to the replacement of an existing unit at the end of its useful life, or the installation of a new chiller or chillers in an existing building (i.e. time of sale) or new construction.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to exceed the efficiency requirements of the baseline defined by the program.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline equipment is assumed to meet the minimum efficiency requirements within the IECC code in effect on the date of the building permit. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Note, users should refer to the website for the Illinois Energy Conservation Code to verify the latest adopted code.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 23 years.[633]

DEEMED MEASURE COST

The incremental capital cost for this measure is provided below:

LOADSHAPE

Loadshape C03 - Commercial Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [638]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [639]

[636] Based on Navigant Consulting, NEEP "Incremental Cost Study Phase Two Final Report", January 2013.
[637] Based on "Water-Cooled Chiller (WCC) (SWHC005-02) Cost Data" by Southern California Edison, November 2020 (SWHC005_Water-Cooled_Chiller_Cost_Data_2020Q3.xlsx)
[638] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[639] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Algorithm

CALCULATION OF SAVINGS

The enhanced electric energy savings calculation should be used as the primary method for more accurate energy savings, with the efficiencies calculated for the specific climate zone and building type for the chiller application. Where the calculated NPLV efficiency of the chiller at the specific conditions is unknown, the basic electric energy savings calculation can be used as a secondary method where the traditional industry-standard IPLV ratings may be more readily available.

ELECTRIC ENERGY SAVINGS

BASIC ELECTRIC ENERGY SAVINGS FOR WATER-COOLED CHILLERS:

$$\Delta kWH = TONS * ((IPLVbase) - (IPLVee)) * EFLH$$

Where:

TONS = chiller actual installed cooling capacity in tons (note: 1 ton = 12,000 Btu/hr)

IPLVbase = efficiency of baseline equipment expressed as Integrated Part Load Value(kW/ton) obtained from current IECC Minimum Efficiency Table – Path (A). Refer to Baseline Efficiency Values by Chiller Type and Capacity in the Reference Tables & Equations section.

IPLVee[640] = efficiency of high efficiency equipment expressed as Integrated Part Load Value (kW/ton)[641]

= Actual installed

EFLH = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

For example, using the default assumptions on the installation of a 150 Ton Centrifugal Water-Cooled Electric Chiller in a Mid-Rise Office in Rockford with an IPLV of .405 kW/ton:

ΔkWh = 150 * (0.550 - 0.405) * 1672

= 36,366 kWh

ENHANCED ELECTRIC ENERGY SAVINGS FOR WATER-COOLED CHILLERS:

$$\Delta kWH = TONS * ((IPLVbase * ILadj) - (NPLV - ILee)) * EFLH$$

Where:

TONS = chiller actual installed cooling capacity in tons (note: 1 ton = 12,000 Btu/hr)

ILadj = adjustment factor to align IPLVbase to Illinois climate and building type. Refer to Table 1 below.

NPLV-ILee[642] = efficiency of proposed high efficiency equipment as Non-Standard Part Load Value (kW/ton) evalutated at Illinois adjusted conditions. All other variables to remain at AHRI standard conditions.

---

[640] Integrated Part Load Value is a seasonal average efficiency rating calculated in accordance with ARI Standard 550/590. It may be calculated using any measure of efficiency (EER, kW/ton, COP), but for consistency with IECC code requirements, it is expressed in terms of IPLV here.

[641] Can determine IPLV from standard testing or looking at engineering specs for design conditions. Standard data is available from AHRI online Certification Directory.

[642] Calculation to be performed using manufacturer-provided efficiency ratings at custom part-load operating points specic to Illinois climate and building type. All other variables to remain at AHRI standard conditions. These custom part-load operating points are based on building load profiles generated from public domain EnergyPlus files developed by Pacific Northwest National Labs in conjunction and with oversight from ASHRAE. The different building types are reflective of certain typical

Chiller manufacturer shall evaluate their chiller's efficiencies at the four unique part-load operating points using entering condenser water temperatures (ECWT) and the adjusted weighted percentages from Table 2 below for the applicable building space type listed[7]. Refer to following NPLV equation:

$$NPLV\ (kw/ton) = 1/[a/A + b/B + c/C + d/D]$$

Where: the lower case letters are the decimal values for weighting and the upper case letters are the chiller efficiency rating at each unique operating point.

EFLH = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

TABLE 1:

Water-Cooled Chillers ILadj Factors to IPLV (Path A) Baseline		
Space Type (occupancy schedule assumption)	Water-Cooled Chiller Type	
	Centrifugal	Screw/Scroll
Office (or unknown[643]) (12hr, 5 days/week)	1.143	1.178
Hospital (24hr, 7 days/week, high occupancy during day)	1.043	1.067
High-Rise Apartments (24hr, 7 days/week, lighter occupancy during day)	1.117	1.155
Primary School (12hr, 5 days/week, seasonal)	1.082	1.127
Hotel (24hr, 7days/week)	1.159	1.186

TABLE 2:

Water-Cooled Chillers NPLV Part-Load Evaluation Conditions Adjusted to Illinois by Building Type								
	% Full Load Cooling Design for Chiller							
	25%		50%		75%		94%	
Space Type	Weight	ECWT [F]	Weight	ECWT [F]	Weight	ECWT [F]	Weight	ECWT [F]
Office (or unknown)	40.1%	68.1	38.3%	74.8	17.9%	80.4	3.7%	84.8
Hospital	15.0%	62.2	44.6%	69.8	35.6%	76.7	4.8%	83.7
High-Rise Apartments	30.1%	68.7	41.6%	73.8	21.3%	78.7	7.0%	83.4
Primary School	25.3%	67.0	26.3%	71.9	31.2%	76.1	17.2%	81.5
Hotel	47.8%	67.0	39.2%	76.1	12.2%	82.2	0.80%	86.9

occupancy schedules. See Reference Tables & Equations section at the end of this measure for additional info and supporting equations.

[643] Office building type is considered a reasonable estimate of the average application.

For example, using the default assumptions on the installation of a 150 Ton Centrifugal Water-Cooled Electric Chiller in a Mid-Rise Office in Rockford with an IPLV of .405 kW/ton:

ΔkWh = 150 * ((0.55 * 1.143) - (1 / ((0.401 / 0.409) + (0.383 / 0.406) + (0.179 / 0.405) + (0.037 / 0.403)))) * 1672

= 55,613.7

BASIC ELECTRIC ENERGY SAVINGS FOR AIR-COOLED CHILLERS:

$$\Delta kWH = TONS * ((12/IPLVbase) - (12/IPLVee)) * EFLH$$

Where:

TONS = chiller actual installed cooling capacity in tons (note: 1 ton = 12,000 Btu/hr)

IPLVbase = efficiency of baseline equipment as Integrated Part Load Value (EER) obtained from current IECC Minimum Efficiency Table – Path (A).. Refer to Baseline Efficiency Values by Chiller Type and Capacity in the Reference Tables & Equations section.

IPLVee[644] = efficiency of proposed high efficiency equipment expressed as Integrated Part Load Value (EER)

EFLH = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

For example, using the default assumptions on the installation of a 150 Ton Centrifugal Air-Cooled Electric Chiller in a Mid-Rise Office in Rockford with an IPLV of 15:

ΔkWh = 150 * ((12 / 14) - (12 / 15)) * 1672

= 14,331.4 kWh

ENHANCED ELECTRIC ENERGY SAVINGS FOR AIR-COOLED CHILLERS:

$$\Delta kWH = TONS * (12/(IPLVbase * ILadj) - 12/(NPLV - ILee)) * EFLH$$

Where:

TONS = chiller actual installed cooling capacity in tons (note: 1 ton = 12,000 Btu/hr)

ILadj = adjustment factor to align IPLVbase to Illinois climate and building type. Refer to Table 3 below.

NPLV-ILee[645] = efficiency of proposed high efficiency equipment as Non-Standard Part Load Value (EER) evalutated at Illinois adjusted conditions. All other variables to remain at AHRI standard conditions. Chiller manufacturer shall evaluate their chiller's efficiencies at the four unique part-load operating points using outdoor design dry bulb (ODDB) and the adjusted weighted percentages from Table 4 below for the applicable building space type listed. Refer to following NPLV equation:

NPLV (EER) = a*A + b*B + c*C + d*D

[644] Integrated Part Load Value is a seasonal average efficiency rating calculated in accordance with AHRI Standard 550/590. It may be calculated using any measure of efficiency (EER, kW/ton, COP), but for consistency with IECC code requirements, it is expressed in terms of IPLV here. IPLV data is available from AHRI online Certification Directory or certified chiller manufacturer's data.

[645] Calculation to be performed using manufacturer-provided efficiency ratings at custom part-load operating points specific to Illinois climate and building type. All other variables to remain at AHRI standard conditions. These custom part-load operating points are based on building load profiles generated from public domain EnergyPlus files developed by Pacific Northwest National Labs in conjunction and with oversight from ASHRAE. The different building types are reflective of certain typical occupancy schedules. See Reference Tables & Equations section at the end of this measure for additional info and supporting equations.

Where: the lower case letters are the decimal values for weighting and the upper case letters are the chiller efficiency rating at each unique operating point.

EFLH = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

TABLE 3:

Air-Cooled Chillers ILadj Factors to IPLV (Path A) Baseline	
Space Type	**Air-Cooled Chiller**
Office (or unknown)	0.860
Hospital	0.925
High-Rise Apartments	0.866
Primary School	0.850
Hotel	0.929

TABLE 4:

Air-Cooled Chillers NPLV Part-Load Evaluation Conditions Adjusted to Illinois by Building Type								
	% Full Load Cooling Design for Chiller							
	25%		50%		75%		94%	
Space Type	**Weight**	**ODDB [F]**	**Weight**	**ODDB [F]**	**Weight**	**ODDB [F]**	**Weight**	**ODDB [F]**
Office (or unknown)	40.1%	69.1	38.3%	77.2	17.9%	83.9	3.7%	89.2
Hospital	15.0%	60.0	44.6%	70.2	35.6%	77.5	4.8%	86.6
High-Rise Apartments	30.1%	67.2	41.6%	75.9	21.3%	83.2	7.0%	89
Primary School	25.3%	68.1	26.3%	74.1	31.2%	79.6	17.2%	85.6
Hotel	47.8%	65.3	39.2%	76.9	12.2%	84.6	0.80%	85.6

For example, using the default assumptions on the installation of a 150 Ton Centrifugal Air-Cooled Electric Chiller in a Mid-Rise Office in Rockford with an IPLV of 15:

ΔkWh = 150 * (12 / (14 * .86) - (12 / ((0.401 * 15.3) + (0.383 * 15.1) + (0.179 * 15) + (0.037 * 14.9)))) * 1,672

= 51,377.5 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$\Delta kW_{SSP} = TONS * ((PEbase) - (PEee)) * CF_{SSP}$

$\Delta kW_{PJM} = TONS * ((PEbase) - (PEee)) * CF_{PJM}$

Where:

PEbase = Peak efficiency of baseline equipment expressed as Full Load (kW/ton)

PEee = Peak efficiency of high efficiency equipment expressed as Full Load (kW/ton)

= Actual installed

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8%

For example, using the default assumptions on the installation of a 150 Ton Centrifugal Water-Cooled Electric Chiller in a Mid-Rise Office in Rockford with a peak efficiency of .409 kW/ton:

ΔkW_{SSP} = 150 * (.550 - .409) * .913

= 19.3

ΔkW_{PJM} = 150 * (.550 - .409) * .478

= 10.1

REFERENCE TABLES

***Chillers Ratings**- Chillers are rated with different units depending on equipment type as shown below

Equipment Type	Unit
Air cooled, electrically operated	Full load EER Part Load EER
Water cooled, electrically operated, positive displacement (reciprocating and rotary screw and scroll)	Full Load kW/ton Part Load kW/ton
Water cooled, electrically operated, centrifugal	Full Load kW/ton Part Load kW/ton

****IPLV Equations and Standard Rating Conditions per AHRI 550/590:**

Expression Of Chiller Efficiency	Equation				
Coefficient Of Performance–COP, W/W, or Energy Efficiency Ratio–EER, Btu/h/W	IPLV or NPLV = 0.01A + 0.42B + 0.45C + 0.12D				
Power Per Ton, kW/ton	IPLV or NPLV = $\frac{1}{\frac{0.01}{A}+\frac{0.42}{B}+\frac{0.45}{C}+\frac{0.12}{D}}$				
	Chiller Energy Efficiency, Load				
	A at 100%	**B** at 75%	**C** at 50%	**D** at 25%	— at 0%
IPLV Rating Conditions					
Condenser, water-cooled only:[a]					
Entering water temperature, F [C]	85 [29.4][b]	75 [23.9]	65 [18.3]	65 [18.3]	65 [18.3]
Flow rate, gpm/ton [Lps per kW]	3.0 [0.054][c]				
Fouling factor, h·ft²·F/Btu [m²·C/W]	0.00025 [0.000044]				
Evaporator:					
Leaving water temperature, F [C]	44 [6.7][b]	—	—	—	44 [6.7]
Flow rate, gpm/ton [Lps per kW]	2.4 [0.043][c]	—	—	—	2.4 [0.043]
Fouling factor, h·ft²·F/Btu [m²·C/W]	0.0001[0.000018]				

***Building Types** - Generalized Occupancy Schedules of Building Types for Reference:

Office –12 hour operation; 5 days a week

Hospital –24 hour operation; 7 days a week; heavier occupancy during the day

High Rise Apts – 24 hour operation; 7 days a week; lighter occupancy during the day

Primary School – 12 hour operation; 5 days a week; seasonal

Hotel –24 hour operation; 7 days a week

****Conversion Factors** – Equations to convert efficiency units where necessary:

kW/ton = 12 / EER

kW/ton = 12 / (COP x 3.412)

COP = EER / 3.412

COP = 12 / (kW/ton) / 3.412

EER = 12 / kW/ton

EER = COP x 3.412

2018 IECC Baseline Efficiency Values by Chiller Type and Capacity (effective 7/1/2019 to 12/31/2022)

			≤ 0.549 IPLV	≤ 0.400 IPLV	≤ 0.500 IPLV	≤ 0.380 IPLV	
	≥ 600 Tons		≤ 0.570 FL	≤ 0.590 FL	≤ 0.560 FL	≤ 0.585 FL	
			≤ 0.539 IPLV	≤ 0.400 IPLV	≤ 0.500 IPLV	≤ 0.380 IPLV	
Air cooled, absorption, single effect	All capacities	COP	≥ 0.600 FL	NA[c]	≥ 0.600 FL	NA[c]	AHRI 560
Water cooled absorption, single effect	All capacities	COP	≥ 0.700 FL	NA[c]	≥ 0.700 FL	NA[c]	
Absorption, double effect, indirect fired	All capacities	COP	≥ 1.000 FL	NA[c]	≥ 1.000 FL	NA[c]	
			≥ 1.050 IPLV		≥ 1.050 IPLV		
Absorption double effect direct fired	All capacities	COP	≥ 1.000 FL	NA[c]	≥ 1.000 FL	NA[c]	
			≥ 1.000 IPLV		≥ 1.050 IPLV		

a. The requirements for centrifugal chiller shall be adjusted for nonstandard rating conditions in accordance with Section C403.3.2.1 and are only applicable for the range of conditions listed in Section C403.3.2.1. The requirements for air-cooled, water-cooled positive displacement and absorption chillers are at standard rating conditions defined in the reference test procedure.

b. Both the full-load and IPLV requirements shall be met or exceeded to comply with this standard. Where there is a Path B, compliance can be with either Path A or Path B for any application.

c. NA means the requirements are not applicable for Path B and only Path A can be used for compliance.

d. FL represents the full-load performance requirements and IPLV the part-load performance requirements.

Absorption double effect, indirect fired	All capacities	COP (W/W)	≥ 1.000 FL	NA[d]	AHRI 560
			≥ 0.150 IPLV.IP		
Absorption double effect, direct fired	All capacities	COP (W/W)	≥ 1.000 FL	NA[d]	AHRI 560
			≥ 1.000 IPLV		

a. Chapter 6 contains a complete specification of the referenced standards, which include test procedures, including the reference year version of the test procedure.
b. The requirements for centrifugal chillers shall be adjusted for nonstandard rating conditions per Section C403.3.2.1 and are applicable only for the range of conditions listed there. The requirements for air-cooled, water-cooled positive displacement and absorption chillers are at standard rating conditions defined in the reference test procedure.
c. Both the full-load and IPLV.IP requirements must be met or exceeded to comply with this standard. When there is a Path B, compliance can be with either Path A or Path B for any application.
d. NA means the requirements are not applicable for Path B, and only Path A can be used for compliance.
e. FL is the full-load performance requirements, and IPLV.IP is for the part-load performance requirements.
f. This table is a replica of ASHRAE 90.1 Table 6.8.1-3 Water-Chilling Packages—Minimum Efficiency Requirements.

MEASURE CODE: CI-HVC-CHIL-V10-250101

REVIEW DEADLINE: 1/1/2028

4.4.7 ENERGY STAR and CEE Tier 2 Room Air Conditioner

DESCRIPTION

This measure relates to the purchase and installation of a room air conditioning unit that meets either the ENERGY STAR[646] or CEE Tier 2 minimum qualifying efficiency specifications, in place of a baseline unit meeting minimum Federal Standard efficiency ratings presented below:[647]

Product Class (Btu/H)	Federal Standard CEER, with louvered sides	Federal Standard CEER, without louvered sides	ENERGY STAR CEER, with louvered sides	ENERGY STAR CEER, without louvered sides	CEE Tier 2 CEER
< 6,000	11.0	10.0	13.1	12.8	14.85
6,000 - 7,999			13.7		
8,000 to 10,999	10.9	9.6	14.7	13.0	14.72
11,000 to 13,999		9.5		12.8	
14,000 to 19,999	10.7	9.3	14.4	12.6	14.45
20,000 to 27,999	9.4	9.4	12.7	12.7	12.69
>= 28,000	9.0		12.2		12.15

Casement	Federal Standard (CEER)	ENERGY STAR (CEER)
Casement-only	9.5	12.8
Casement-slider	10.4	14.0

Reverse Cycle - Product Class (Btu/H)	Federal Standard CEER, with louvered sides	Federal Standard CEER, without louvered sides	ENERGY STAR CEER, with louvered sides	ENERGY STAR CEER, without louvered sides
< 14,000	N/A	9.3	N/A	12.6
>= 14,000	N/A	8.7	N/A	11.7
< 20,000	9.8	N/A	13.2	N/A
>= 20,000	9.3	N/A	12.6	N/A

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

[646] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[647] Federal Baselines defined by Code of Federal Regulations §430.32(d). ENERGY STAR specification defined by Version 5.0 Room Air Conditioners, effective October 30, 2023. CEE specification defined by Room Air Conditioner Specification effective May 17, 2022.
Side louvers that extend from a room air conditioner model in order to position the unit in a window. A model without louvered sides is placed in a built-in wall sleeve and are commonly referred to as "through-the-wall" or "built-in" models.
Casement-only refers to a room air conditioner designed for mounting in a casement window of a specific size.
Casement-slider refers to a room air conditioner with an encased assembly designed for mounting in a sliding or casement window of a specific size. Reverse cycle refers to the heating function found in certain room air conditioner models.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the new room air conditioning unit must meet the ENERGY STAR efficiency standards presented above.

DEFINITION OF BASELINE EQUIPMENT

The baseline assumption is a new room air conditioning unit that meets the current minimum federal efficiency standards presented above.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 12 years. [648]

DEEMED MEASURE COST

The incremental cost for this measure is assumed to be $40 for an ENERGY STAR unit and $261 for a CEE Tier 2 unit.[649]

LOADSHAPE

Loadshape C03 - Commercial Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [650]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [651]

Algorithm

CALCULATION OF SAVINGS

ENERGY SAVINGS

$$\Delta kWh = (FLH_{RoomAC} * Btu/h * (1/CEER_{base} - 1/CEER_{ee}))/1000$$

Where:

FLH_{RoomAC} = Full Load Hours of room air conditioning unit

= Equivalent Full Load Hours for cooling in Existing Buildings are provided in section 4.4 HVAC End Use

[648] Measure Life Report, Residential and Commercial/Industrial Lighting and HVAC Measures, GDS Associates, June 2007.
[649] ENERGY STAR cost based on field study conducted by Efficiency Vermont and Tier 2 based on Efficiency Vermont's characterization of the NEEP Mid-Atlantic TRM's (version 9.0, October 2019) incremental cost analysis. See 'room-ac-cost-analysis-10.2023.xlsx.'
[650] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[651] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year

Btu/h = Input capacity of unit

= Actual. If unknown assume 8,500 Btu/hr [652]

$CEER_{base}$ = Combined Energy Efficiency Ratio of baseline unit

= As provided in tables above

$CEER_{ee}$ = Combined Energy Efficiency Ratio of ENERGY STAR or CEE Super Efficient unit

= Actual. If unknown assume minimum qualifying standard as provided in tables above

For example, for an 8,500 Btu/h capacity ENERGY STAR unit, with louvered sides, in an unknown location in Rockford:

$\Delta kWH_{ENERGY\ STAR}$ = (1133 * 8500 * (1/10.9 – 1/14.7)) / 1000

= 228.4 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = Btu/h * ((1/CEER_{base} - 1/CEER_{ee}))/1000) * CF$$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [653]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8%[654]

Other variable as defined above

For example, for an 8,500 Btu/h capacity ENERGY STAR unit, with louvered sides, in Rockford during system peak:

$\Delta kW_{ENERGY\ STAR}$ = ((8500 * (1/10.9 – 1/14.7)) / 1000) * 0.913

= 0.184 kW

4.4.8 Guest Room Energy Management (PTAC & PTHP)

DESCRIPTION

This measure applies to the installation of a temperature setback and lighting control system for individual guest rooms. The savings are achieved based on Guest Room Energy Management's (GREM's) ability to automatically adjust the guest room's set temperatures and control the HVAC unit for various occupancy modes.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Guest room temperature set point must be controlled by automatic occupancy detectors or keycard that indicates the occupancy status of the room. During unoccupied periods the default setting for controlled units differs by at least 5 degrees from the operating set point. Theoretically, the control system may also be tied into other electric loads, such as lighting and plug loads to shut them off when occupancy is not sensed. This measure bases savings on improved HVAC controls. If the system is connected to lighting and plug loads, additional savings would be realized. The incentive is per guestroom controlled, rather than per sensor, for multi-room suites. Replacement or upgrades of existing occupancy-based controls are not eligible for an incentive.

DEFINITION OF BASELINE EQUIPMENT

Guest room energy management thermostats replace manual heating/cooling temperature set-point and fan On/Off/Auto thermostat controls. Two possible baselines exist based on whether housekeeping staff are directed to set-back (or turn off) thermostats when rooms are not rented.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for GREM is 15 years.[655]

DEEMED MEASURE COST

$260/unit.

The incremental cost documented for this measure is $260 per room HVAC controller, which is the cost difference between a non-programmable thermostat and a GREM.[656]

LOADSHAPE

Loadshape C03 - Commercial Cooling

COINCIDENCE FACTOR

A coincidence factor is not used in the determination of coincident peak kW savings.

Algorithm

CALCULATION OF SAVINGS

Below are the annual kWh savings per installed EMS for different sizes and types of HVAC units. The savings are achieved based on GREM's ability to automatically adjust the guest room's set temperatures and control the HVAC unit to maintain set temperatures for various occupancy modes. Note that care should be taken in selecting a value

[655] DEER 2008 value for energy management systems.

[656] This value was extracted from Smart Ideas projects in PY1 and PY2.

consistent with actual baseline conditions (e.g., whether housekeeping staff are directed to set-back/turn-off the thermostats when rooms are unrented). Different values are provided for Motels and Hotels since significant differences in shell performance, number of external walls per room and typical heating and cooling efficiencies result in significantly different savings estimates. Energy savings estimates are derived using a prototypical EnergyPlus simulation of a motel and a hotel.[657] Model outputs are normalized to the installed capacity and reported here as kWh/Ton, coincident peak kW/Ton and Therms/Ton.

4.4.9 Air and Water Source Heat Pump Systems (Centrally Ducted and Ductless)

DESCRIPTION

This measure applies to the installation of high-efficiency air cooled and water source heat pump systems with conditioned air delivered to the building via ductwork, ductless systems and "hybrid" systems that work in conjunction with fuel-fired heating systems. This measure could apply to replacing an existing unit at the end of its useful life, or installation of a new unit in a new or existing building.

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be a high-efficiency air cooled or water source, heat pump system that exceeds the baseline and meets program requirements.

DEFINITION OF BASELINE EQUIPMENT

New construction / Time of Sale: To calculate savings with an electric baseline, the baseline equipment is assumed to be a standard-efficiency air cooled or water source heat pump system that meets the Code energy efficiency requirements (IECC or Code of Federal Regulations whichever is higher) in effect on the date of equipment purchase (if date unknown assume current Code minimum). The rating conditions for the baseline and efficient equipment efficiencies must be equivalent.

To calculate savings with a furnace/ AC baseline, the baseline equipment is assumed to meet the Code energy efficiency requirements (IECC or Code of Federal Regulations whichever is higher).

Where unknown, the baseline should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition.

In order for this characterization to apply, the baseline equipment is assumed to meet the efficiency requirements within the IECC code in effect on the date of the building permit. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Note, IECC 2021 is became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code. If evaluation determines the applicable version of code, given location and timing, isn't an appropriate baseline due to supply constraints, low compliance, or other issues, the previous iteration of code may be used through 2023.

IECC 2021 leverages new DOE testing methods and associated metrics. The following conversion factors are recommended for use if the efficient equipment is not rated under the new testing procedure but the stipulated baseline is:[658]

SEER2 = X * SEER

EER2 = X * EER

HSPF2 = X * HSPF

Where:

X	SEER2	EER2	HSPF2
Ducted	0.95	0.95	0.85
Ductless	1.00	1.00	0.90
Packaged	0.95	0.95	0.84

[658] Consortium for Energy Efficiency (CEE), Testing, Testing, M1, 2, 3, Transitioning to New Federal Minimum Standards, CEE Summer Program Meeting, August, 2022.

Note: new Federal Standards affecting heat pumps and air conditioning equipment became effective January 1, 2023.

Early replacement / Retrofit: The baseline for this measure is the efficiency of the *existing* heating and cooling equipment for the assumed remaining useful life of the existing unit and a new baseline heating and cooling system meeting the code energy efficiency requirements (IECC or Code of Federal Regulations whichever is higher) for the remainder of the measure life.

A weighted average early replacement rate is provided for use in programs when the actual baseline early replacement rates are unknown.

Deemed Early Replacement Rates For ASHP[659]

Equipment Type	Full System Displacement	Partial System Displacement
Cooling	30%	30%
Heating	30%	100%

Note to apply these deemed early replacement rates, an assumption of the percentage of replacements that are full displacement v partial displacement is required. This should be determined through evaluation, or a deemed ratio of 100% Full Displacement for ducted ASHPs and 50% Full: 50% Partial for Ductless ASHPs can be used. Savings should be calculated following both the full and partial displacement methodology and then this ratio should be used to weight the savings accordingly.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 16 years.[660]

Remaining life of existing equipment is assumed to be 6 years for ASHP and Central AC, 6 years for furnace, 8 years for boilers[661] and 16 years for electric resistance.[662]

DEEMED MEASURE COST

Ducted Air Source Heat Pumps:

New Construction and Time of Sale: For analysis purposes, the incremental capital cost for this measure is assumed as $100 per ton for commercially sized air-cooled units.[663] The incremental cost for all other equipment types should be determined on a site-specific basis.

[659] Consistent with Residential assumptions – should be updated with Commercial data when available. Program tracking data from ComEd and Ameren between 2018 and 2020 was used to develop these assumptions. During this period the air source heat pump programs operated downstream and projects were classified as Time of Sale or Early Replacement. Note that any fuel switch scenario at the time would have been classified as Time of Sale and therefore the rates provided likely represent a low estimate of the true early replacement rates. In the absence of alternative data, the TAC agreed to apply these rates and the deemed full v partial displacement assumptions listed, but these assumptions should be revisited through future evaluation.

[660] Consistent with Residential measure and based on 2016 DOE Rulemaking Technical Support document, as recommended in Guidehouse 'ComEd Effective Useful Life Research Report', May 2018.

[661] Assumed to be one third of effective useful life of replaced equipment.

[662] Assume full measure life (16 years) for replacing electric resistance as we would not expect that resistance heat would fail during the lifetime of the efficient measure.

[663] Based on a review of TRM incremental cost assumptions from Vermont, Wisconsin, and California.

For residential sized ASHP, defaults provided below:[664]

Capacity Range	Incremental Cost per Ton[665]
< 2 tons	$88
≥ 2 to < 3 tons	$70
≥ 3 to < 4 tons	$59
≥ 4 tons	$57

Early Replacement: The actual full installation cost of the Heat Pump (including any necessary electrical or distribution upgrades required) should be used. The assumed deferred cost of replacing existing equipment with a new baseline unit should also be incorporated.

Ductless Minisplit Heat Pumps:

New Construction and Time of Sale: The actual installed cost of the DMSHP (including any necessary electrical or distribution upgrades required) should be used (defaults are provided below), minus the assumed installation cost of the baseline equipment, or assume $4,019 for a new baseline 80% AFUE furnace, or $8,820 for a new 84% AFUE boiler.[666]

The assumed baseline cost for electric equipment is provided below.[667]

Baseline Equipment Type	Capacity Range	Baseline Cost ($/Ton)
Centrally Ducted Air Source Heat Pumps	< 2 tons	$4,602
	≥ 2 to < 3 tons	$3,691
	≥ 3 to < 4 tons	$3,093
	≥ 4 tons	$2,992
Ductless Minisplit Heat Pumps	< 1 ton	$8,156
	≥ 1 to < 2 tons	$5,356
	≥ 2 to < 3 tons	$3,704
	≥ 3 tons	$3,670
Central Air Conditioning	< 2 tons	$2,340
	≥ 2 to < 3 tons	$1,900
	≥ 3 tons	$1,500

Default full cost of the DMSHP is provided below.:[668]

Unit Size	Full Install Cost ($/ton)[669]
< 1 ton	$8,312 + ($600* (HSPF2-7.8))

[664] In 2025, a working group was created to update costs for residential HVAC equipment. Heat Pump and Central Air Conditioning costs are based upon Ameren program data. Furnace and Boiler costs are based on Ameren, Nicor, People's Gas, and North Shore Gas program data. Baseline costs have been determined using ratios from Updated Buildings Sector Appliance and Equipment Costs and Efficiencies by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration. See file "HVAC Costs – 071825_VEIC.xlsx" for more details.

[667] Ibid

[668] Ibid

[669] Ibid

Unit Size	Full Install Cost ($/ton)[669]
≥ 1 to < 2 tons	$5,458 + ($600* (HSPF2-7.8))
≥ 2 to < 3 tons	$3,775 + ($600* (HSPF2-7.8))
≥ 3 tons	$3,740 + ($600* (HSPF2-7.8))

The incremental cost of the DSMHP compared to a baseline minimum efficiency DSMHP is provided in the table below:[670]

Unit Size	Incremental Cost ($/ton)
< 1 ton	$156
≥ 1 to < 2 tons	$102
≥ 2 to < 3 tons	$71
≥ 3 tons	$70

Early Replacement/retrofit (replacing existing equipment): The actual full installation cost of the DMSHP (including any necessary electrical or distribution upgrades required) should be used. The assumed deferred cost (after the appropriate number of years described above in the 'Deemed Lifetime of Efficient Equipment' section) of replacing existing equipment with a new baseline unit is provided in table below for electric equipment, or is assumed to be $4,601 for a new baseline 80% AFUE furnace or $10,563 for a new 84% AFUE boiler.[671] If replacing electric resistance heat, there is no deferred replacement cost. This future cost should be discounted to present value using the nominal societal discount rate.

Equipment Type	Capacity Range	Deferred Baseline Cost per Ton
Centrally Ducted Air Source Heat Pumps	< 2 tons	$5,268
	≥ 2 to < 3 tons	$4,226
	≥ 3 to < 4 tons	$3,541
	≥ 4 tons	$3,425
Ductless Minisplit Heat Pumps	< 1 ton	$9,337
	≥ 1 to < 2 tons	$6,132
	≥ 2 to < 3 tons	$4,240
	≥ 3 tons	$4,202
Central Air Conditioning	< 2 tons	$2,679
	≥ 2 to < 3 tons	$2,175
	≥ 3 tons	$1,717

Where the DMSHP is a supplemental HVAC system, the full installation cost of the DMSHP (including any necessary electrical or distribution upgrades required) should be used without a deferred replacement cost.

If the install cost is unknown a default is provided above. Fuel switch scenarios are likely to require additional installation work which may include adding new electrical circuits, capping existing gas lines and upgrading electrical panels. These costs are likely to range significantly and actual values should be used wherever possible. If unknown, assume an additional $300 for fuel switch installations.

LOADSHAPE

Loadshape C05 - Commercial Electric Heating and Cooling

[670] Ibid

[671] All baseline replacement costs are consistent with their respective measures and include inflation rate of 2.28%.

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [672]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [673]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC AND FOSSIL FUEL ENERGY SAVINGS

Non fuel switch measures:

$$\Delta kWh_{Non\ Fuel\ Switch} = ASHPSiteCoolingImpact + ASHPSiteHeatingImpact$$

Where:

For units with cooling capacities less than 65 kBtu/hr (ASHP only):

ASHPSiteCoolingImpact = $((CoolingLoad/DuctlessSave * (1/(SEER2_base))) - (CoolingLoad * 1/(SEER2_ee\ )))/1{,}000$

ASHPSiteHeatingImpact = $((HeatLoad_Disp/DuctlessSave * (1/(HSPF2_base * HSPF2_ClimateAdj))) - (HeatLoad_Disp * 1/(HSPF2_ee * HSPF2_ClimateAdj)))\ /\ 1{,}000$

For ASHP units with cooling capacities equal to or greater than 65 kBtu/hr and all WSHPs:

$$\Delta kWh_{Non\ Fuel\ Switch} = ASHPSiteCoolingImpact + ASHPSiteHeatingImpact$$

Where:

ASHPSiteCoolingImpact = $((CoolingLoad * (1/(IEER_base))) - (CoolingLoad * 1/(IEER_ee\ )))/1{,}000$

ASHPSiteHeatingImpact = $(HeatLoad_Disp\ /\ 3{,}412 * (1/COP_base - 1/COP_ee))$

Fuel switch measures:

Fuel switch measures must produce positive total lifecycle energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows (note for early replacement measures the lifetime savings should be

[672] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[673] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

calculated by calculating savings for the remaining useful life of the existing equipment and for the remaining measure life):

SiteEnergySavings (MMBTUs) = $FuelSwitchSavings + NonFuelSwitchSavings$

FuelSwitchSavings = $GasHeatReplaced - HPSiteHeatConsumed$

NonFuelSwitchSavings = $FurnaceFanSavings + HPSiteCoolingImpact$

For units with cooling capacities less than 65 kBtu/hr (ASHP only):

ASHPSiteHeatConsumed =$((HeatLoad_Disp * (1/(HSPF2_ee * HSPF2_ClimateAdj * PD_Adj))) / 1{,}000 * 3{,}412) / 1{,}000{,}000$

ASHPSiteCoolingImpact = $(((CoolingLoad/DuctlessSave * (1/(SEER2_base)) - ((CoolingLoad * 1/(SEER2_ee)))/1{,}000 * 3412) / 1{,}000{,}000$

FurnaceFanSavings =$(FurnaceFlag * HeatLoad_Disp/DuctlessSave * 1/AFUE_{base} * Fe) / 1{,}000{,}000$

GasHeatReplaced = $(HeatLoad_Disp/DuctlessSave * 1/AFUE_{base}) / 1{,}000{,}000$

For ASHP units with cooling capacities greater than 65 kBtu/hr and all WSHPs:

ASHPSiteHeatConsumed =$(HeatLoad_Disp * (1/(COP_ee * PD_Adj)) / 1{,}000{,}000$

ASHPSiteCoolingImpact = $(((CoolingLoad * (1/(IEER_base)) - ((CoolingLoad * 1/(IEER_ee)))/1{,}000 * 3{,}412) / 1{,}000{,}000$

FurnaceFanSavings = $(FurnaceFlag * HeatLoad_Disp * 1/AFUE_{base} * F_e) / 1{,}000{,}000$

GasHeatReplaced = $(HeatLoad_Disp * 1/AFUE_{base}) / 1{,}000{,}000$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Note for Early Replacement measures, the efficiency terms of the existing unit should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 6 years for furnace, 8 years for boilers, 15

years for electric resistance), and the efficiency terms for a new baseline unit should be used for the remaining years of the measure. See assumptions below.

Programs where existing system unknown

In programs where the existing fuel or system type is unknown, savings should be apportioned between the Fuel Switch and Non- Fuel Switch scenarios, as follows:

Savings from Non-Fuel Switch (kWh) $=(1 - \%FuelSwitch) * \Delta kWh_{Non\ Fuel\ Switch}$

Plus

Savings from Fuel Switch (MMBtu converted to appropriate fuel as table above)

$= \%FuelSwitch * SiteEnergySavings\ (MMBTUs)$

Where:

%FuelSwitch = The percentage of replacements resulting in fuel-switching.

= 1 when fuel switching is known, 0 if non fuel switch

= when unknown, e.g. midstream program, determine via evaluation

CoolingLoad = Annual cooling load for the building

= $EFLH_{cool}$ * $Capacity_{cool}$

$Capacity_{cool}$ = Output capacity of the cooling equipment in Btu per hour (1 ton of cooling capacity equals 12,000 Btu/hr).

= Actual installed

$SEER2_{base}$ = Seasonal Energy Efficiency Ratio of the baseline equipment

= SEER from tables below, based on the applicable Code on the date of equipment purchase (if unknown assume current Code).

$SEER2_{ee}$ = Seasonal Energy Efficiency Ratio of the energy efficient equipment.

= Actual installed

$EFLH_{cool}$ = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

DuctlessSave = Factor used to adjust ducted heating or cooling load displaced by ductless systems that are not subject to losses from existing ductwork.

= 1-0.15 = 0.85 for ducted system displaced by ductless system

= 1.00 for ducted system displaced by ducted system or ductless system displaced by ductless system

$HSPF2_{base}$ = Heating Seasonal Performance Factor of the baseline equipment

= HSPF from tables below, based on the applicable Code on the date of equipment purchase (if unknown assume a blended baseline value of 4.0 HSPF2[674]).

$HSPF2_{ee}$ = Heating Seasonal Performance Factor of the energy efficient equipment.

= Actual installed. If rating is COP, HSPF = COP * 3.413

[674] Blended Baseline value came from percentage of accounts with heat pumps (15%) at 7.5 HSPF2 and electric furnaces (85%) at 3.412 HSPF, based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024.

HSPF_ClimateAdj = Adjustment factor to account for observed discrepency between seasonal heating performance relative to rated HSPF as provided by standard AHRI 210/240 rating conditions. Note, the adjustment is dependent on the test method use for the rating (i.e. HSPF or HSPF2 rating) [675]:

City (county based upon)	HSPF_ClimateAdj When using HSPF2 rating
1 (Rockford)	77%
2 (Chicago)	77%
3 (Springfield)	91%
4 (Belleville)	91%
5 (Marion)	91%
Weighted Average[676]	
ComEd	77%
Ameren	89%
Statewide	80%

$IEER_{base}$ = Integrated Energy Efficiency Ratio of the baseline equipment

= IEER (or EER2) from tables below, based on the applicable Code on the date of equipment purchase (if unknown assume current Code). For air-cooled units < 65 kBtu/hr, assume the following conversion from SEER2 to EER2 for calculation of peak savings:[677]

$$EER2 = (-0.02 * SEER2^2) + (1.12 * SEER2)$$

$IEER_{ee}$ = Integrated Energy Efficiency Ratio (or EER2) of the energy efficient equipment. For air-cooled units < 65 kBtu/hr, if the actual $EER2_{ee}$ is unknown, assume the conversion from SEER2 to EER2 as provided above.

= Actual installed

HeatLoad_Disp = Annual heat load for the building displaced by the ASHP (Btus)

$= EFLH_{heat} * Capacity_{heat} * HeatLoadFactor$

$EFLH_{heat}$ = heating mode equivalent full load hours in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

$Capacity_{heat}$ = output capacity of the heat pump equipment in Btu per hour.

= Actual installed

HeatLoadFactor = Portion of HeatLoad displaced by ASHP in partial displacement applications. Varies by Switchover Temperature and Climate Region. If Switchover Temperature is unknown, use 32°F.

[675] Adjustment factors are based on findings from NEEA, July 2020 'EXP07:19 Load-based and Climate-Specific Testing and Rating Procedures for Heat Pumps and Air Conditioners'. See 'NEEA HP data' for calculation. Findings were consistent with other reviewed sources including ASHRAE, 2020 'Right-Sizing Electric Heat Pump and Auxiliary Heating for Residential Heating Systems Based on Actual Performance Associated with Climate Zone' and Cadmus, 2022 'Residential ccASHP Building Electrification Study'. The difference between HSPF and HSPF2 ratings is based on the change in testing procedure that will correct for some of this effect where ducted systems will have an approximately 9% lower HSPF2 rating as compared to HSPF, based on CEE presentation, July 2022, 'Testing Testing, M1, 2, 3: Transitioning to New Federal Minimum Standards'.

[676] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[677] Based on Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder. Note this is appropriate for single speed units only.

= 1.0 if full displacement (e.g. cold climate heat pumps and water source heat pumps) or if switchover temperature is lower than 17°F or if Partial Displacement with simultaneous operation

Climate Zone (City based upon)	HeatLoadFactor (by Switchover Temperature)[678]										
	47°F	44°F	41°F	38°F	35°F	32°F	29°F	26°F	23°F	20°F	17°F

3412 = Btu per kWh.

COP_{base} = coefficient of performance of the baseline equipment

= COP from tables below, based on the applicable Code on the date of equipment purchase (if unknown assume current Code). If rating is HSPF2, COP = HSPF2 / 3.413

COP_{ee} = coefficient of performance of the energy efficient equipment.

= Actual installed. If rating is HSPF2, COP = HSPF2 / 3.413

$AFUE_{base}$ = Baseline Annual Fuel Utilization Efficiency Rating. For early replacement measures, use actual AFUE rating for the remaining useful life of the existing equipment (6 years for furnace, 8 years for boilers). For new systems (time of sale, new construction or remaining years of early replacement), use appropriate code level efficiency.

FurnaceFlag = 1 if system replaced is a gas furnace, 0 if not.

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 7.7%[682]

%IncentiveElectric = % of total incentive paid by electric utility

= Actual

%IncentiveGas = % of total incentive paid by gas utility

= Actual

Code of Federal Redulations (baseline effective 1/1/2019):[683]

Equipment type	Cooling capacity	Heating type	Cooling Efficiency level	Heating Efficiency level	Compliance date
Small Commercial Packaged Air Conditioning and Heating Equipment (Air-Cooled)	≥65,000 Btu/h and <135,000 Btu/h	Electric Resistance Heating or No Heating	IEER = 12.2 IEER = 14.1	N/A	1/1/2018 1/1/2024
		All Other Types of Heating	IEER = 12.0 IEER = 13.9	COP = 3.3 COP = 3.4	1/1/2018 1/1/2024
		Electric Resistance Heating or No Heating	IEER = 11.6 IEER = 13.5	N/A	1/1/2018 1/1/2024

[682] F_e is estimated using TRM models for the three most popular building types for programmable thermostats: low-rise office (10.2%), sit-down restaurant (8.6%), and retail – strip mall (4.4%). 7.7% reflects the average Fe of the three building types. See "Fan Energy Factor Example Calculation 2021-06-23.xlsx" for reference.

[683] Code of Federal Regulations: Table 3 to §431.97—Updates to the Minimum Cooling Efficiency Standards for Air Conditioning and Heating Equipment and Table 4 to §431.97—Updates to the Minimum Heating Efficiency Standards for Air-Cooled Air Conditioning and Heating Equipment [Heat Pumps]. For 1/1/2024 compliance dates, note these manufacturing and import federal standards go into effect on 1/1/2023. The measure characterization is recommending delaying adopting these standards until 1/1/2024.

Equipment type	Cooling capacity	Heating type	Cooling Efficiency level	Heating Efficiency level	Compliance date
Large Commercial Packaged Air Conditioning and Heating Equipment (Air-Cooled)	≥135,000 Btu/h and <240,000 Btu/h	All Other Types of Heating	IEER = 11.4 IEER = 13.3	COP = 3.2 COP = 3.3	1/1/2018 1/1/2024
Very Large Commercial Packaged Air Conditioning and Heating Equipment (Air-Cooled)	≥240,000 Btu/h and <760,000 Btu/h	Electric Resistance Heating or No Heating	IEER = 10.6 IEER = 12.5	N/A	1/1/2018 1/1/2024

Non Fuel Switch example, a 5-ton single phase split system 60,000 Btuh capacity heat pump, with an efficiency SEER2 of 16, and an efficient HSPF2 of 9.5, at a new restaurant in Chicago with a building permit dated after 1/1/2023 saves:

ΔkWh =$Annual\ kWh\ Savings_{cool} + Annual\ kWh\ Savings_{heat}$

Annual kWh Savings$_{cool}$ = $(Capacity_{cool} * EFLH_{cool} * (1/SEER_{base} - 1/SEER_{ee}))/1000$

Annual kWh Savings$_{heat}$ =$(HeatLoad * (1/(HSPF_{base} * HSPF_ClimateAdj) - 1/(HSPF_{ee} * HSPF_ClimateAdj)/1000$

ΔkWh = (60,000 * 761 * (1/14.3 – 1/16))/1000 + (60,000 * 797 * (1/(7.5 * 0.7) – 1/(9.5 * 0.7))/1000

= 2257 kWh

Fuel Switch Illustrative Examples

[for illustrative purposes 50:50 Incentive is used for joint programs]

New construction using gas furnace and central AC baseline:

For example, a 60,000 Btu, 16 SEER2, 9.5 HSPF2 single phase split system Air Site Heat Pump installed in a new Chicago restaurant, in place of a 120,000 Btuh natural gas furnace and 5 ton Central AC unit:

SiteEnergySavings (MMBTUs) = $GasHeatReplaced + FurnaceFanSavings - HPSiteHeatConsumed + HPSiteCoolingImpact$

GasHeatReplaced = $(HeatLoad * 1/AFUE_{base})$ / 1,000,000

= $(60{,}000 * 797 * 1/0.8)$ / 1000000

= 59.8 $MMBtu$

FurnaceFanSavings =$(FurnaceFlag * HeatLoad * 1/AFUE_{base} * F_e)$ / 1,000,000

= $(1 * 60{,}000 * 797 * 1/0.8 * 0.077)$ / 1,000,000

= 4.6 $MMBtu$

HPSiteHeatConsumed = $((HeatLoad * (1/(HSPF_{ee} * HSPF_ClimateAdj))) /1000 * 3412)/1{,}000{,}000$

= $((60{,}000 * 797 * (1/(9.5 * 0.77))) / 1000 * 3412) / 1{,}000{,}000$

= 22.3 $MMBtu$

HPSiteCoolingImpact = $((FLHcool * Capacity_{cool} * (1/SEER_{base} - 1/SEER_{ee}))/1000 * 3412) / 1{,}000{,}000$

= $((761 * 60{,}000 * (1/14.3 - 1/16)) / 1000 * 3412)/1{,}000{,}000$

= 1.2 $MMBtu$

SiteEnergySavings (MMBTUs) = 59.8 + 4.6 – 22.3 + 1.2 = 43.3 MMBtu [Measure is eligible]

Fuel Switch Illustrative Example continued

Savings would be claimed as follows:

Measure supported by:	Electric Utility claims:	Gas Utility claims:
Electric utility only	43.3 * 1,000,000/3412 = 12,691 kWh	N/A
Electric and gas utility	0.5 * 43.3 * 1,000,000/3412 = 6,345 kWh	0.5 * 43.3 * 10 = 217 Therms
Gas utility only	N/A	43.3 * 10 = 433 Therms

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = ((Capacity_{cool}/DuctlessSave * 1/EER2_base) - (Capacity_{cool} * 1/EER2_ee)) / 1000 * CF$$

Where CF value is chosen between:

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [684]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [685]

For example, a 5 ton single phase split system air source heat pump, with an efficient EER2 of 12.5 with a building permit dated after 1/1/2023 saves:

ΔkW = ((60,000/1 * 1/9.4) – (60,000 * 1/12.5))/1000 *0.913

= 1.44 kW

FOSSIL FUEL SAVINGS

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from gas to electric.

[684] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[685] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

For the purposes of forecasting load reductions due to fuel switch ASHP projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure. For Early Replacement measures, the efficiency terms of the existing unit should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 7 years for furnace, 8 years for boilers or GSHP, 15 years for electric resistance), and the efficiency terms for a new baseline unit should be used for the remaining years of the measure.

ΔTherms = $[Heating\ Consumption\ Replaced]$

= $[(\%FuelSwitch * HeatLoad_Disp/DuctlessSave * 1/AFUE_{base}) / 100{,}000]$

ΔkWh = $[FurnaceFanSavings] - [HP\ heating\ consumption] + [Cooling\ savings]$

For units with cooling capacities less than 65 kBtu/hr:

= $\%FuelSwitch * [FurnaceFlag * HeatLoad_Disp/DuctlessSave * 1/AFUE_{base} * F_e * 0.000293] - [(HeatLoad_Disp * (1/(HSPF2_{ee} * HSPF2_ClimateAdj * PD_Adj))/1000] + [((CoolingLoad/DuctlessSave * 1/SEER2_{base}) - (CoolingLoad * 1/SEER2_{ee}))/1000]$

For units with cooling capacities greater than 65 kBtu/hr:

= $\%FuelSwitch * [FurnaceFlag * HeatLoad_Disp * 1/AFUE_{base} * F_e * 0.000293] - [HeatLoad_Disp/3412 * 1/(COP_{ee} * PD_Adj)] + [(CoolingLoad * (1/IEER_{base} - 1/IEER_{ee}))/1000]$

MEASURE CODE: CI-HVC-HPSY-V14-260101

REVIEW DEADLINE: 1/1/2028

4.4.10 High Efficiency Boiler

DESCRIPTION

To qualify for this measure the installed equipment must be replacement of an existing boiler at the end of its service life, in a commercial or multifamily space with a high efficiency, gas-fired steam or hot water boiler. High efficiency boilers achieve gas savings through the utilization of a sealed combustion chamber and multiple heat exchangers that remove a significant portion of the waste heat from flue gasses. Because multiple heat exchangers are used to remove waste heat from the escaping flue gasses, some of the flue gasses condense and must be drained.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a boiler used 80% or more for space heating, not process, and boiler AFUE, E_T (thermal efficiency), or E_C (combustion efficiency) rating must be rated greater than or equal to 85% for hot water boilers and 83% for steam boilers.

DEFINITION OF BASELINE EQUIPMENT

Dependent on when the unit is installed and whether the unit is hot water or steam. The baseline efficiency source is the Energy Independence and Security Act of 2007 with technical amendments from Federal Register, volume 81, Number 10, January 15, 2016 for boilers <300,000 and Federal Register, volume 74, Number 139, July 22, 2009 for boilers >300,000 Btu/hr.[686]

For boilers <300,000 Btu/hr the technical amendments include the recent compliance dates for gas-fired hot water and steam boilers manufactured on or after January 15, 2021.[687]

Note, for natural draft steam boilers, as IECC 2021, Illinois state energy code that is expected to become effective statewide in 2024, exceeds the minimum federal efficiency standards, it was replaced in favor of the more aggressive thermal efficiency values in the table below. For new construction applications where the permitting date is prior to the state's adoption of IECC 2021, it is recommended to use the applicable edition of IECC corresponding to that timeline. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Each gas-fired commercial packaged boiler must meet the applicable energy conservation standard levels detailed in the table below.

Boiler baseline efficiency standards

Boiler Type	Efficiency
Hot Water Boiler < 300,000 Btu/h	84% AFUE
Hot Water Boiler ≥ 300,000 Btu/h and ≤ 2,500,000 Btu/h	80% E_T
Hot Water Boiler > 2,500,000 Btu/h	82% E_C
Steam Boiler < 300,000 Btu/h	82% AFUE
Steam Boiler ≥ 300,000 Btu/h and ≤ 2,500,000 Btu/h	79% E_T
Steam Boiler ≥ 2,500,000 Btu/h	79% E_T

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 25 years.[688]

[686] Energy Conservation Standards for Commercial Boilers, Code of Federal Regulations, 10 CFR 431.87
[687] Code of Federal Regulations, effective January 15, 2021 (10 CFR 432(e)(3)).
[688] Consistent with DOE assumption determined through a literature review in Appendix 8-F of the Department of Energy Commercial Technical Support Document.

DEEMED MEASURE COST

The measure cost for this technology is tiered based on the boiler type and combustion efficiencies. As installation costs for the base case and the measure case units are assumed to be the same, labor costs are not specified for this measure.

Incremental and Gross Measure costs for Space Heating Boilers

Boiler Type	Incremental Measure Cost ($/KBtu)[689]	Full Installed Measure Cost ($/KBtu)[690]
Hot Water Boiler ≥85% E_C and <90% E_C	$2.17	$12.94
Hot Water Boiler ≥90% E_C	$12.17	$22.95
Steam Boiler ≥83% E_C and <85% E_C	$4.35	$19.24
Modular Steam Boiler Arrays (≥85% E_C)[691]	Custom

Boiler Capacity and Distribution Type	Efficiency
Hot Water ≥300,000 & ≤2,500,000 Btu/hr[693]	80% E_T
Hot Water Boiler > 2,500,000[694]	82% E_C

Steam boiler baseline:

Boiler Capacity and Distribution Type	Efficiency
Steam <300,000 Btu/hr[695]	82% AFUE
Steam Boiler ≥ 300,000 Btu/h and ≤ 2,500,000 Btu/h [696]	79% E_T
Steam - natural draft ≥300,000 & ≤2,500,000 Btu/hr	79% TE[697]
Steam Boiler >2,500,000 Btu/h	79% E_T
Steam - natural draft >2,500,000 Btu/hr	79% E_T [698]

$Efficiency_{EE}$ = Efficent Boiler Efficiency Rating

=actual value, specified to one significant digit (i.e., 95.7%)

For example, a 150,000 btu/hr water boiler meeting AFUE 90% is installed in Rockford at a high rise office building , in the year 2022

ΔTherms = 2,089* 150,000 * (0.90-0.840)/0.840) / 100,000 Btu/Therm

= 224 Therms

4.4.11 High Efficiency Furnace

DESCRIPTION

This measure covers the installation of a residential sized (<225,000 Btu/hr) or commercial sized (>=225,000 Btu/hr) high efficiency gas furnace in lieu of a standard efficiency gas furnace in a commercial or industrial space. Note commercial sized condensing gas units (>= 225,000 Btu/hr) heating 100% outside air should use 4.4.37 Unitary HVAC Condensing Furnace if appropriate. High efficiency gas furnaces achieve savings through the utilization of a sealed, super insulated combustion chamber, more efficient burners, and multiple heat exchangers that remove a significant portion of the waste heat from the flue gasses. Because multiple heat exchangers are used to remove waste heat from the escaping flue gasses, most of the flue gasses condense and must be drained.

This measure also describes savings from a brushless permanent magnet (BPM) motor (known and referred in this measure as an electronically commutated motor (ECM)) compared to a lower efficiency motor within a residential sized unit. Time of Sale and New Construction scenarios can no longer claim these electrical savings, as federal standards make ECM blower fan motors a requirement for residential-sized furnaces.[699] Savings however are available from replacing an operational inefficient furnace with a new furnace with an ECM prior to the end of its life.

This measure was developed to be applicable to the following program types: TOS, NC and EREP. If applied to other program types, the measure savings should be verified.

Time of sale:

a. The installation of a new high efficiency, gas-fired condensing furnace in a commercial location. This could relate to the replacement of an existing unit at the end of its useful life, or the installation of a new system.

Early replacement:

Early Replacement determination will be based on meeting the following conditions:

- The existing unit is operational when replaced, or
- The existing unit requires minor repairs (<$528).[700]
- All other conditions will be considered Time of Sale.

The Baseline AFUE of the existing unit replaced:

- If the AFUE of the existing unit is known, the Baseline AFUE is the actual AFUE value of the unit replaced.
- If the AFUE of the existing unit is unknown, use assumptions in variable list below (AFUE(exist)).
- If the operational status or repair cost of the existing unit is unknown, use time of sale assumptions.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a furnace with input energy less than 225,000 Btu/hr rated natural gas fired furnace with an Annual Fuel Utilization Efficiency (AFUE) rating and fan electrical efficiency exceeding the program requirements:

DEFINITION OF BASELINE EQUIPMENT

Time of Sale: The current Federal Standard for gas furnaces <225,000 Btu/hr is an AFUE rating of 80%.

[699] As part of the code of federal regulations, energy conservation standards for covered residential furnace fans become effective on July 3, 2019 (10 CFR 430.32(y)). The expectation is the baseline will essentially become an ECM motor.
[700] The Technical Advisory Committee agreed that if the cost of repair is less than 20% of the new baseline replacement cost it can be considered early replacement. Note the non-inflated cost is used as this would be a cost consideration in the program year.

For furnaces ≥225,000 Btu/hr, the baseline AFUE rating is 81%.

Early replacement: The baseline for this measure is the efficiency of the existing equipment for the assumed remaining useful life of the unit and a new baseline 80% AFUE for Residential sized or 81% AFUE for Commercial sized unit for the remainder of the measure life.

DEFINITION OF MEASURE LIFE

The expected measure life is assumed to be 16.5 years.[701]

Remaining life of existing equipment is assumed to be 5.5 years.[702]

DEEMED MEASURE COST

For residential sized units (<225,000 Btu/hr):

Time of Sale: The incremental capital cost for this measure depends on efficiency as listed below:[703]

AFUE	Installation Cost	Incremental Install Cost
Baseline	$4,019	n/a
≤ 95%	$4,327	$307
> 95% - < 97%	$4,524	$505
≥ 97%	$4,699	$679

Early Replacement: The full installation cost is provided in the table above. The assumed deferred cost (after 5.5 years) of replacing existing equipment with a new 80% baseline unit is assumed to be $4,5504.[704] This cost should be discounted to present value using the nominal discount rate.

For commercial sized units (≥225,000 Btu/hr) – actual costs should be used.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Residential sized (<225,000 Btu/hr), Early Replacement Only:

For remaining useful life of the existing furnace (assumed 5.5 years):

$$\Delta kWh = Heating\ Savings\ +\ Cooling\ Savings\ +\ Shoulder\ Season\ Savings$$

[701] Average of 15-18 year lifetime estimate made by the Consortium for Energy Efficiency in 2010.
[702] Assumed to be one third of effective useful life.
[703] In 2025, a working group was created to update costs for residential HVAC equipment. Heat Pump and Central Air Conditioning costs are based upon Ameren program data. Furnace and Boiler costs are based on Ameren, Nicor, People's Gas, and North Shore Gas program data. Baseline costs have been determined using ratios from Updated Buildings Sector Appliance and Equipment Costs and Efficiencies by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration. See file "HVAC Costs – 071825_VEIC.xlsx" for more details.
[704] Baseline cost assumption inflated using 2.28% rate.

Where:

Heating Savings = Brushless DC motor or Electronically commutated motor (ECM)
= 418 kWh[705]

Cooling Savings = Brushless DC motor or electronically commutated motor (ECM) savings during cooling season

If air conditioning = 263 kWh

If no air conditioning = 175 kWh

If unknown (weighted average)= 241 kWh[706]

Shoulder Season Savings = Brushless DC motor or electronically commutated motor (ECM) savings during shoulder seasons

= 51 kWh

For example, a blower motor in a low rise office building where air conditioning presence is unknown:

ΔkWh = Heating Savings + Cooling Savings + Shoulder Season Savings
= 418 +241 + 51
= 710 kWh

For remaining measure life of the existing furnace (next 11 years): 0 kWh

All other applications assume 0 kWh.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Residential sized (<225,000 Btu/hr) Early Replacement Only:

For remaining useful life of the existing furnace (assumed 5.5 years):

For units that have evaporator coils and condensing units and are cooling in the summer in addition to heating in the winter the summer coincident peak demand savings should be calculated. If the unit is not equipment with coils or condensing units, the summer peak demand savings will not apply.

$$\Delta kW = (CoolingSavings/HOURSyear) * CF$$

Where:

HOURSyear = Actual hours per year if known, otherwise use hours from Table below for building type:[707]

Building Type	HOURSyear	Model source
Assembly	2150	eQuest
Assisted Living	4373	eQuest

[705] To estimate heating, cooling and shoulder season savings for Illinois, VEIC adapted results from a 2009 Focus on Energy study of BPM blower motor savings in Wisconsin. This study included effects of behavior change based on the efficiency of new motor greatly increasing the amount of people that run the fan continuously. The savings from the Wisconsin study were adjusted to account for different run hour assumptions (average values used) for Illinois. See: FOE to IL Blower Savings.xlsx.
[706] The weighted average value is based on assumption that 75% of buildings installing BPM furnace blower motors have Central AC.
[707] Hours per year are estimated using the eQuest or OpenStudio models as the total number of hours the cooling system is operating for each building type.

For example, a blower motor in a low rise office building where air conditioning presence is unknown:

ΔkW = (241 / 2481) * 0.474

= 0.05 kW

For remaining measure life of the existing furnace (next 11 years): 0 kW

All other applications assume 0 kWh.

FOSSIL FUEL SAVINGS

Time of Sale:

$$\Delta\text{Therms} = (EFLH * Capacity * (AFUE(eff) / AFUE(base) - 1)) / 100{,}000$$

Early replacement[709]:

ΔTherms for remaining life of existing unit (1st 5.5 years):

$$\Delta\text{Therms} = (EFLH * Capacity * (AFUE(eff) / AFUE(exist) - 1)) / 100{,}000$$

ΔTherms for remaining measure life (next 11 years):

$$\Delta\text{Therms} = (EFLH * Capacity * (AFUE(eff) / AFUE(base) - 1)) / 100{,}000$$

Where:

[709] The two equations are provided to show how savings are determined during the initial phase of the measure (existing to efficient) and the remaining phase (new baseline to efficient). In practice, the screening tools used may either require a First Year savings (using the first equation) and then a "number of years to adjustment" and "savings adjustment" input which would be the (new base to efficient savings)/(existing to efficient savings).

EFLH = Equivalent Full Load Hours for heating in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use

Capacity = Nominal Heating Input Capacity Furnace Size (Btu/hr) for efficient unit not existing unit

= custom Furnace input capacity in Btu/hr

AFUE(exist) = Existing Furnace Annual Fuel Utilization Efficiency Rating

= Use actual AFUE rating where it is possible to measure or reasonably estimate.

If unknown, assume 64.4 AFUE%. [710]

AFUE(base) = Baseline Furnace Annual Fuel Utilization Efficiency Rating

= For residential sized units (<225,000 Btu/hr): 80%[711]

= For commercial sized units (>=225,000 Btu/hr):

Program	AFUE(base)
Time of Sale	81%[712]
Early Replacement	81%[713]

AFUE(eff) = Efficent Furnace Annual Fuel Utilization Efficiency Rating.

= Actual. If Unknown, assume 95%.[714]

For example,

ΔTherms = (1428 * 150,000 * (0.92 / 0.80 – 1))/ 100,000

= 321 Therms

[714]Minimum ENERGY STAR efficiency after 2.1.2012.

4.4.12 Infrared Heaters

DESCRIPTION

A natural gas-fired radiant infrared heater uses the combustion of natural gas to heat a metal tube or ceramic panel to a very high temperature (typically between 1200 and 5000 degrees Fahrenheit). The high surface temperature causes radiant heat transfer between the heater surface and its surroundings. The surroundings will re-radiate the heat to occupants and release heat through convection to the air, providing a comfortable environment without directly heating air.

Infrared heaters are ideal for space heating applications where there are elevated ceilings with high thermal stratification, spaces with high ventilation or air infiltration rates, or a need for spot heating within an unconditioned or industrial space. Aircraft hangers, warehouses, greenhouses, manufacturing production areas, pools, and loading docks are space types that can be efficiently served by a radiant infrared heater.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a natural gas heater with an electric ignition that uses non-conditioned air for combustion. Gross Radiant Coefficient (GRC) is provided by the manufacturer and defined as the ratio of radiant heat output to the natural gas input energy (in Btu).[715]

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a standard natural gas fired warm air heater.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years.[716]

DEEMED MEASURE COST

The incremental capital cost for this measure is $2.70 per kBtu/hr input capacity.[717]

[717] Ibid

FOSSIL FUEL SAVINGS

Natural gas savings for this measure are based on the standard practice of HVAC designers to size a gas-fired radiant infrared heater at a lower input capacity than an equivalent warm air unit heater for an identical application.

$$\Delta\text{Therms} = Therms(base) - Therms(IR)$$

$$\text{Therms(base)} = Capacity/RSF * EFLH/100{,}000$$

$$\text{Therms(IR)} = Capacity * EFLH/100{,}000$$

Where:

Capacity = Input capacity of radiant infrared heater in btu/hr

= Actual

RSF = Radiation Sizing Factor, dependent on Gross Radiant Coefficient[718] as listed below:[719,720]
If Gross Radiant Coefficient is unavailable, assume RSF = 0.85.

Gross Radiant Coefficient (GRC)	RSF (Radiation Sizing Factor)
GRC < 0.67	0.85
0.67 ≤ GRC	0.70

EFLH = Equivalent Full Load Hours for heating in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use

100,000 = Btu to therm conversion factor

For example: a radiant heater with a natural gas input capacity of 125,000 Btu/hr and a Gross Radiant Coefficient of 0.45 installed in a warehouse in Chicago will save:

ΔTherms = Therms(base) – Therms(IR)

Therms(base) = 125,000/0.85*1286/100,000 = 1891.176 Therms

Therms(IR) = 125,000*1286/100,000 = 1607.500 Therms

ΔTherms = 1891.176 – 1670.500 = 283.676 Therms

REVIEW DEADLINE: 1/1/2027

4.4.13 Package Terminal Air Conditioner (PTAC) and Package Terminal Heat Pump (PTHP)

DESCRIPTION

A PTAC is a packaged terminal air conditioner that cools and sometimes provides heat through an electric resistance heater (heat strip). A PTHP is a packaged terminal heat pump. A PTHP uses its compressor year round to heat or cool. In warm weather, it efficiently captures heat from inside your building and pumps it outside for cooling. In cool weather, it captures heat from outdoor air and pumps it into your home, adding heat from electric heat strips as necessary to provide heat.

This measure characterizes:

Time of Sale: the purchase and installation of a new efficient PTAC or PTHP.

Early Replacement: the early removal of existing HVAC system from service, prior to its natural end of life, and replacement with a new efficient PTAC or PTHP unit. Savings are calculated between existing unit and efficient unit consumption during the remaining life of the existing unit, and between new baseline unit and efficient unit consumption for the remainder of the measure life.

This measure was developed to be applicable to the following program types: TOS NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be PTACs or PTHPs that exceed baseline efficiencies.

DEFINITION OF BASELINE EQUIPMENT

Time of Sale: the baseline condition is equipment that meets the Code energy efficiency requirements (IECC or Code of Federal Regulations whichever is higher) in effect on the date of equipment purchase (if date is unknown, assume current Code minimum).

Early Replacement: the baseline is the existing HVAC equipment for the assumed remaining useful life of the unit and the new baseline as defined above for the remainder of the measure life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 8 years.[721]

Remaining life of existing equipment is assumed to be 3 years.[722]

DEEMED MEASURE COST

Time of Sale: The incremental capital cost for this equipment is estimated to be $84/ton.[723]

Early Replacement: The measure cost is the full cost of removing the existing unit and installing a new one. The actual program cost should be used. If unknown assume $1,047 per ton.[724]

The assumed deferred cost (after 5 years) of replacing existing equipment with new baseline unit is assumed to be $1,077 per ton.[725] This cost should be discounted to present value using the nominal discount rate.

[721] Based on 2015 DOE Technical Support Document, as recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.
[722] Standard assumption of one third of effective useful life.
[723] DEER 2008. This assumes that baseline shift from IECC 2012 to IECC 2015 carries the same incremental costs. Values should be verified during evaluation.
[724] Based on DCEO – IL PHA Efficient Living Program data.
[725] Based on subtracting TOS incremental cost from the DCEO data and incorporating inflation rate of 2.28%.

LOADSHAPE

Loadshape R10 – Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67.0% [726]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5% [727]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS

Non Fuel Switch Measures

Electric savings for PTACs and PTHPs should be calculated using the following algorithms

Time of Sale:

PTAC ΔkWh[728] = $Annual\ kWh\ Savings_{cool}$

PTHP ΔkWh =$Annual\ kWh\ Savings_{cool} + Annual\ kWh\ Savings_{heat}$

Annual kWh Savings$_{cool}$ = $CoolingLoad * (1/EER_{base} - 1/EER_{ee})$

Annual kWh Savings$_{heat}$ = $(HeatLoad * (1/COP_{base} - 1/COP_{ee}))/3.412$

Early Replacement:

ΔkWh for remaining life of existing unit (1st 3years) = Annual kWh Savings$_{cool}$ + Annual kWh Savings$_{heat}$

Annual kWh Savings$_{cool}$ = $CoolingLoad * (1/EER_{exist} - 1/EER_{ee})$

Annual kWh Savings$_{heat}$ = $(HeatLoad * (1/COP_{exist} - 1/COP_{ee}))/3.412$

ΔkWh for remaining measure life (next 5 years) =$Annual\ kWh\ Savings_{cool} + Annual\ kWh\ Savings_{heat}$

Annual kWh Savings$_{cool}$ = $CoolingLoad * (1/EER_{base} - 1/EER_{ee})$

Annual kWh Savings$_{heat}$ = $(HeatLoad * (1/COP_{base} - 1/COP_{ee}))/3.412$

Fuel switch measures:

[726] Based on All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems, Cadmus, October 2015.
[727]Based on All-Electric Homes PY6 Metering Results: Multi-family HVAC Systems, Cadmus, October 2015.
[728] There are no heating efficiency improvements for PTACs since although some do provide heating, it is always through electric resistance and therefore the COP_{base} and COP_{ee} would be 1.0.

Fuel switch measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

SiteEnergySavings (MMBTUs) = $FuelSwitchSavings + NonFuelSwitchSavings$

FuelSwitchSavings = $(GasHeatReplaced - ElectricHeatConsumed)$

NonFuelSwitchSavings = $CoolingImpact$

Where:

GasHeatReplaced = $(HeatLoad * 1/FossilEff_{base}) / 1{,}000$

ElectricHeatConsumed = $(HeatLoad * 1/COP_{ee}) / 1000$

CoolingImpact = $CoolLoad * ((1/EER_{base}) - (1/EER_{ee})) * 3{,}412/1{,}000{,}000$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Note for Early Replacement measures, the efficiency terms of the existing unit should be used for the remaining useful life of the existing equipment and the efficiency terms for a new baseline unit should be used for the remaining years of the measure. See assumptions below.

Where:

CoolingLoad = Annual cooling load for the space being served

= $kBtu/hr_{cool}$ * $EFLH_{cool}$

$kBtu/hr_{cool}$ = capacity of the cooling equipment in kBtu per hour (1 ton of cooling capacity equals 12 kBtu/hr).

= Actual installed

$EFLH_{cool}$ = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use:

HeatLoad = Annual heat load for the space being served

= $kBtu/hr_{heat}$ * $EFLH_{heat}$

$kBtu/hr_{heat}$ = capacity of the heating equipment in kBtu per hour.

= Actual installed

$EFLH_{heat}$ = Equivalent Full Load Hours for heating in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use

EER_{exist} = Energy Efficiency Ratio of the existing equipment

= Actual. If unknown assume 10.4 EER for PTAC and for PTHP.[729]

EER_{base} = Energy Efficiency Ratio of the baseline equipment; see the table below for values.

= Based on applicable Code on date of equipment purchase (if unknown assume current Code

Copy of Table C403.2.3(3): Minimum Efficiency Requirements: Electrically operated packaged terminal air conditioners, packaged terminal heat pumps

PTHP (Cooling mode) Non-Standard Size*	10.8 – (0.213 x Cap/1000) EER	10.8 – (0.213 x Cap/1000) EER Compliance date: 10/7/2010
PTHP (Heating mode) Standard Sized	3.2 – (0.026 x Cap/1000) COP	3.7 – (0.052 x Cap/1000) COP Compliance date: 10/8/2012
PTHP (Heating mode) Non-Standard Size*	2.9 – (0.026 x Cap/1000) COP	2.9 – (0.026 x Cap/1000) COP Compliance date: 10/7/2010

Table notes: "Cap" = The rated cooling capacity of the project in Btu/hr. If the units capacity is less than 7000 Btu/hr, use 7,000 Btu/hr in the calculation. If the unit's capacity is greater than 15,000 Btu/hr, use 15,000 Btu/hr in the calculations.

*** Non-Standard Size apply only to units with existing sleeves less than 16 inches (406mm) in height and less than 42 inches (1067 mm) in width. Replacement unit shall be factory labeled as follows "MANUFACTURED FOR REPLACEMENT APPLICATIONS ONLY; NOT TO BE INSTALLED IN NEW CONSTRUCTION PROJECTS".**

EER_{ee} = Energy Efficiency Ratio of the energy efficient equipment. For air-cooled units < 65 kBtu/hr, if the actual EER_{ee} is unknown, assume the following conversion from SEER to EER for calculation of peak savings[730]: $EER = (-0.02 * SEER^2) + (1.12 * SEER)$

= Actual installed

3.412 = Btu per Wh.

COP_{exist} = coefficient of performance of the existing equipment

= Actual. If unknown assume 1.0 COP for PTAC units and 2.9 COP for PTHPs[731]

COP_{base} = coefficient of performance of the baseline equipment; see table above for values.

COP_{ee} = coefficient of performance of the energy efficient equipment.

= Actual installed.

[729] Efficiency of existing unit is estimated based on the 2015/2018 IECC building energy code standard sized, and assuming a 1 ton unit; PTAC: EER = 14.0 – (0.3 * 12,000/1,000) = 10.4, and PTHP: EER = 14 – (0.3 * 12,000/1,000) = 10.4.
[730] Based on Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder. Note this is appropriate for single speed units only.
[731] Efficiency of existing unit is estimated based on the 2015/2018 IECC building energy code, and assuming a 1 ton unit; COP = 3.2 – (0.026 * 12,000/1,000) = 2.9.

$FossilEff_{base}$ = Efficiency of baseline or existing fossil fuel heating system

= Actual or select baseline from applicable measure in Section 4.

Time of Sale (assuming new construction baseline):

For example, a 1 ton PTAC with an efficient EER of 12 in a guest room of a hotel in Rockford with a building permit dated after 1/1/2016 saves:

= [(12) * [(1/10.4) – (1/12)] * 1,042

= 160 kWh

Early Replacement (assuming replacement baseline for deferred replacement in 3 years):

For example, a 1 ton PTHP with an efficient EER of 12, COP of 3.0 in a guest room of a hotel in Rockford replaces a PTAC unit (with electric resistance heat) with unknown efficiency.

ΔkWh for remaining life of existing unit (1st 3 years)

= (12 * (1/10.4 – 1/12) * 1,042) + (12/3.412 * (1/1.0 – 1/3.0) * 1,758)

= 160 + 4,122

= 4,282 kWh

ΔkWh for remaining measure life (next 5 years)

= (12 * (1/10.4 – 1/12) * 1,042) + (12/3.412 * (1/1.0 – 1/3.0) * 1,758)

= 160 + 4,122

= 4,282 kWh

For example, a 1 ton PTHP with an efficient EER of 12, COP of 3.0 in a guest room of a hotel in Rockford in place of a 80% central boiler providing heat and a baseline PTAC.

SiteEnergySavings (MMBTUs) = FuelSwitchSavings + NonFuelSwitchSavings

FuelSwitchSavings = (GasHeatReplaced – ElectricHeatConsumed)

NonFuelSwitchSavings = CoolingImpact

GasHeatReplaced = (HeatLoad * 1/$FossilEff_{base}$) / 1,000

= (12 * 1,758 * 1/0.8) / 1,000

= 26.4 MMBtu

ElectricHeatConsumed = (HeatLoad * 1/COP_{ee}) / 1,000

= (12 * 1,758 * 1/3) / 1,000

= 7.0 MMBtu

CoolingImpact = CoolLoad * (1/EER_{base} – 1/EER_{ee}) * 3,412/1,000,000

= 12 * 1,042 * (1/10.4 – 1/12) * 3,412/1,000,000

= 0.5 MMBtu

SiteEnergySavings (MMBTUs) = 26.4 – 7.0 + 0.5

= 19.9 MMBtu

If supported by an electric utility: ΔkWh = ΔSiteEnergySavings * 1,000,000 / 3,412

= 19.9 * 1,000,000/3,412

= 5,832 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Time of Sale:

$$\Delta kW = (kBtu/hr_{cool}) * [(1/EER_{base}) - (1/EER_{ee})] * CF$$

Early Replacement:

ΔkW for remaining life of existing unit (1st 3 years)=$(kBtu/hr_{cool}) * [(1/EER_{exist}) - (1/EER_{ee})] * CF$

ΔkW for remaining measure life (next 5 years) = $(kBtu/hr_{cool}) * [(1/EER_{base}) - (1/EER_{ee})] * CF$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67.0% [732]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

[732] Based on All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems, Cadmus, October 2015.

= 28.5% [733]

Time of Sale:

For example, a 1 ton replacement cooling unit with no heating with an efficient EER of 12 with a building permit dated after 1/1/2016 saves:

ΔkW_{SSP} = (12 * (1/10.4 – 1/12) *0.67

= 0.1031 kW

For example, a 1 ton PTHP with an efficient EER of 12, COP of 3.0 replacing a PTAC unit with unknown efficiency saves:

ΔkW for remaining life of existing unit (1st 3 years):

ΔkW_{SSP} = 12 * (1/10.4 – 1/12) * 0.67

= 0.1031 kW

ΔkW for remaining measure life (next 5 years):

ΔkW_{SSP} = 12 * (1/10.4 – 1/12) * 0.67

= 0.1031 kW

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = $[Gas\ Heat\ Replaced]$

= $(HeatLoad\ *\ 1/FossilEff_{base})\ /\ 100$

ΔkWh = $-\ [Electric\ Heat\ Added]\ +\ [CoolingImpact]$

= $-((HeatLoad\ *\ 1/COP_{ee})\ /\ 3.412)\ +\ (CoolLoad\ *\ (1/EER_{base}\ -\ 1/EER_{ee}))$

MEASURE CODE: CI-HVC-PTAC-V14-260101

REVIEW DEADLINE: 1/1/2030

[733] Based on All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems, Cadmis, October 2015.

4.4.14 Pipe Insulation

DESCRIPTION

This measure provides rebates for installation of 1" – 4" fiberglass, foam, calcium silicate or other types of insulation with similar insulating properties to existing bare pipe on straight piping as well as other pipe components such as elbows, tees, valves, and flanges for all non-residential installations.

Savings are provided in two forms; default savings estimates on a per linear foot basis and savings calculated with a multitude of varying parameters with the use of an external calculator[734]. The default savings estimates are provided in the 'Calculation of Savings' section below. They provide estimated savings for measure applications with select and default parameters. The external tool, however, allows more flexibility and provides comprehensive analysis to pipe insulation projects, accounting for all on-site variables.

Default per linear foot savings estimates are provided for both exposed indoor or above ground outdoor piping distributing fluid in the following system types (natural gas fired systems only):

- Hydronic heating systems (with or without outdoor reset controls), including:
    - boiler systems that do not circulate water around a central loop and operate upon demand from a thermostat ("non-recirculation")
    - systems that recirculate during heating season only ("Recirculation – heating season only")
    - systems recirculating year-round ("Recirculation – year-round")
- Domestic hot water
- Low and high-pressure steam systems
    - non-recirculation
    - recirculation - heating season only
    - recirculation - year round

With the use of the external tool to account for varying parameter inputs, savings are calculated using the "Pipe Insulation" calculator available on the Nicor Gas website at: https://www.nicorgas.com/emerging. Savings are approached through the following inputs:

- Pipe Material: Copper, Steel, Stainless Steel
- Pipe Location: Indoor (Heated, Semi-Heated,[735] Unheated, Unspecified) or Outdoor
- Application: Hot Water Space Heating, Steam (5, 15, 40, 65, 100, 150 psi) for various system types detailed in the subsequent system type list below
- Thermal Regain Factor (based on pipe location)
- Building Type [736]
- Nominal Pipe Size (inches)
- Insulation Thickness (inches): 1"-4", specified in ½" increments [737]
- Hot Water/Steam Boiler Efficiency (%): 75%-90%, specified in 2.5% increments
- Climate Zone: Rockford, Chicago, Springfield, Belleville, Marion
- Length of Installed Pipe (feet)
- Number of Elbows, Tees, Flanges, and/or Valves [738]

[734] Please see; 'C&I Pipe Insulation Calculator Access.docx' for directions on accessing the external calculator. The use of other comparable external calculators are allowed if the functionality mirrors the savings approach detailed in this characterization.
[735] Unconditioned space with heat transfer to conditioned space (e.g. boiler room, ceiling plenum, basement, crawlspace, wall, etc.).
[736] Comprehensive list of building types available in Section 4.4, HVAC End Use of IL TRM.
[737] For insulation thicknesses greater than 4", savings can be claimed based on 4" insulation thickness.
[738] Equivalent length of elbows and tees is based on methodology described in ANSI/ASME B36.19. Equivalent length of flanges and valves is based on methodology described in ATSM Standard C1129-12.

Process piping can also use the algorithms provided but requires custom entry of hours.

For new construction applications, minimum qualifying nominal pipe diameter is 1". Piping must have at least 1" of insulation and outdoor piping must include an all-weather protective jacket. New advanced insulating materials may be thinner, and savings can be calculated with 3E Plus v4.1.

The relevant code of compliance should be followed for direction on minimum permitted insulation thickness for a nominal pipe diameter. As per the International Energy Conservation Code (IECC) 2021, the minimum permitted insulation thickness is 1" for installations pertaining to new construction or major renovation heating HVAC applications [739]. However, there are exceptions based on Fluid Operating Temperature Range, Insulation thermal conductivity range, install locations and pipe sizes –indicating the minimum insulation thickness required for parameters described in the column headers presented in the table below.

Fluid Operating Temperature Range and Usage (°F)	Insulation Conductivity		Nominal Pipe or Tube Size (inches)				
	Conductivity Btu.in/(h.ft$^{2.°F)}$	Mean Rating Temperature, °F	<1	1 to <1.5	1.5 to <4	4 to <8	≥8
>350	0.32 - 0.34	250	4.5	5.0	5.0	5.0	5.0
251 - 350	0.29 - 0.32	200	3.0	4.0	4.5	4.5	4.5
201 - 250	0.27 - 0.30	150	2.5	2.5	2.5	3.0	3.0
141 - 200	0.25 - 0.29	125	1.5	1.5	2.0	2.0	2.0
105 - 140	0.21 - 0.28	100	1.0	1.0	1.5	1.5	1.5
40 -60	0.21 - 0.27	75	0.5	0.5	1.0	1.0	1.0
<40	0.20 - 0.26	50	0.5	1.0	1.0	1.0	1.5

Note – The above table is not representative of the applicability of the workpaper measure and does not reflect any limitations in the web-based calculator. This is merely the requirements cited by the IECC 2018 code for pipe insulation.

This measure was developed to be applicable to the following program types: RF, DI

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is installing pipe wrap insulation to a length of pipe. Indoor piping must have at least 1" of insulation (or equivalent R-value) and outdoor piping must have at least 2" of insulation (or equivalent R-value) and include an all-weather protective jacket. Minimum qualifying pipe diameter is 1." Insulation must be continuous and contiguous over fittings that directly connect to straight pipe, including elbows and tees.[740]

DEFINITION OF BASELINE EQUIPMENT

The base case for savings estimates is a bare pipe. Pipes are required by new construction code to be insulated but are still commonly found uninsulated in older commercial buildings.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 15 years.[741]

[739] International Energy Conservation Code, 2018; Section C403.11.3 Piping Insulation (Mandatory), Table C403.11.3, Page C-69.
[740] *ASHRAE Handbook—Fundamentals*, 23.14; Hart, G., "Saving energy by insulating pipe components on steam and hot water distribution systems", *ASHRAE Journal*, October 2011.

DEEMED MEASURE COST

Actual costs should be used if known. Otherwise, the deemed measure costs below based on RS Means[742] pricing reference materials may be used.[743] The following table summarizes the estimated costs for this measure per foot of insulation added and include installation costs:

Insulation Thickness				
	1 Inch	1.5 Inches	2 Inches	2.5 Inches

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

N/A

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

Δtherms per foot[744] $= [((Q_{base} - Q_{eff}) * EFLH) / (100{,}000 * \eta_{Boiler})] * TRF$

$= [Modeled\ or\ provided\ by\ tables\ below] * TRF$

Δtherms $= (L_{sp} + L_{oc,i}) * \Delta therms\ per\ foot$

Where:

EFLH = Equivalent Full Load Hours for Heating in Existing Buildings or New Construction

= Actual or defaults by building type provided in Section 4.4, HVAC end use

For year-round recirculation or domestic hot water:

= 8,766

For heating season recirculation, hours with the outside air temperature below 55°F:

Zone	Hours
Zone 1 (Rockford)	5,039
Zone 2 (Chicago)	4,963
Zone 3 (Springfield)	4,495
Zone 4 (Belleville/	4,021
Zone 5 (Marion)	4,150

Q_{base} = Heat Loss from Bare Pipe (Btu/hr/ft)

= Calculated where possible using 3E Plusv4.1 software. For defaults see table below

Q_{eff} = Heat Loss from Insulated Pipe (Btu/hr/ft)

= Calculated where possible using 3E Plusv4.1 software. For defaults see table below

100,000 = conversion factor (1 therm = 100,000 Btu)

η_{Boiler} = Efficiency of the boiler being used to generate the hot water or steam in the pipe

= Actual or if unknown use default values given below:

= 80% for hot water boilers [745]

= 79% for steam boilers [746]

[744] This value comes from the reference table "Savings Summary by Building Type and System Type." The formula and the input tables in this section document assumptions used in calculation spreadsheet "Pipe Insulation Savings 2013-11-12.xlsx".

[745] Federal Register, volume 74, Number 139, July 22, 2009 for boilers >300,000 Btu/hr

[746] Ibid.

TRF = Thermal Regain Factor for pipe location and use, see table below. The Custom TRF option may be used on any pipe location, including pipe locations with deemed TRFs specifically listed in the table below, if supporting justification and calculations for the Custom TRF are provided.

May vary seasonally such as: TRF[summer] * summer hours + TRF[winter] * winter hours where TRF values reflecting summer and winter conditions are apportioned by the hours for those conditions. TRF may also be adjusted by building specific balance point temperature (BPT) and operating hours above and below that BPT.[747]

Pipe Location	Assumed Regain	TRF, Thermal Regain Factor
Outdoor	0%	1.0
Indoor, conditioned space during the heating season, 55°F BPT	85%	0.15
Indoor, conditioned space, not during the heating season, 55°F BPT	0%	1.0
Indoor, conditioned, annual use (e.g., hot water or process loads), 55°F BPT	45%	0.55
Indoor, semi- conditioned, (unconditioned space, with heat transfer to conditioned space. E.g., boiler room, ceiling plenum, basement, crawlspace, wall), during the heating season, 55°F BPT	30%	0.70
Indoor, semi-conditioned, not during the heating season, 55°F BPT	0%	1.0
Indoor, semi-conditioned, annual use, 55°F BPT	16%	0.84
Indoor, unconditioned spaces, (no heat transfer to conditioned space)	0%	1.0
Location not specified - Commercial	23%	0.77
Location not specified – Industrial	16%	0.84
Custom	Custom	1 – assumed regain

L_{sp} = Length of straight pipe to be insulated (linear foot)

= actual installed (linear foot)

$L_{oc,I}$ = Total equivalent length of the other components (valves and tees) of pipe to be insulated

= Actual installed (linear foot). See table "Equivalent Length of Other Components – Elbows and Tees" for equivalent lengths.

The heat loss estimates (Q_{base} and Q_{eff}) were developed using the 3E Plus v4.1 software program.[748] The energy savings analysis is based on adding 1-inch (indoor) or 2-inch (outdoor) thick insulation around bare pipe. The thermal conductivity of pipe insulation varies by material and temperature rating; to obtain a typical value, a range of materials allowed for this measure were averaged. For insulation materials not in the table below, use 3E Plusv4.0 software to calculate Q_{base} and Q_{eff}.

[747] Zimmerman, Cliff, Franklin Energy, "Thermal Regain Factor_4-30-14.docx", 2014. Based on climate zone 2. Note 'Location not specified – Commercial' assumes semi-conditioned spaces with 50% pipes providing space heating and 50% providing DHW. 'Location not specified – Commercial' assumes semi-conditioned annual usage.

[748] 3E Plus is a heat loss calculation software provided by the NAIMA (North American Insulation Manufacturer Association).

Insulation Type	Conductivity (Btu.in / hr.ft^2.ºF @ 75F)	Max temp (ºF)
Polyethylene foam	0.25	200
Flexible polyurethane-based foam	0.27	200
Fiberglass	0.31	250
Melamine foam	0.26	350
Flexible silicon foam	0.40	392
Calcium silicate	0.40	1200
Cellular glass	0.31	400
Average conductivity of all these materials (Btu.in / hr.ft^2.ºF @ 75ºF)	0.31	

The pipe fluid temperature assumption used depends upon both the system type and whether there are outdoor reset controls:

System Type	Fluid temperature assumption (˚F)
Hot Water space heating with outdoor reset - Non recirculation	145
Hot Water space heating without outdoor reset - Non recirculation	170
Hot Water space heating with outdoor reset – Recirculation heating season only	145
Hot Water space heating without outdoor reset – Recirculation heating season only	170
Hot Water space heating with outdoor reset – Recirculation year-round	130
Hot Water space heating without outdoor reset – Recirculation year-round	170
Domestic Hot Water	125
5 psi Steam (low pressure)	225
15 psi Steam (low pressure)	250
40 psi Steam (low pressure)	287
65 psi Steam (high pressure)	312
100 psi Steam (high pressure)	338
150 psi Steam (high pressure)	365

For Example, a DHW water boiler in an unconditioned indoor space with 100 feet of 4" steel pipe, and 20 each of pipe elbows, tees, flanges, and valves installing 2.5" of polyethylene foam would save:

$$\Delta\text{therms per foot} = (((Q_{base} - Q_{eff}) * EFLH) / (100{,}000 * n_{Boiler})) * TRF$$

$$= ((((0.8 * 252.6) - (0.25 * 252.6) * 8{,}766) / (100{,}000 * 81.9\%)) * 0.77$$

$$= 11.4 \text{ therms per foot}$$

$$\Delta\text{therms} = (L_{sp} + L_{oci}) * \Delta\text{therms per foot}$$

$$= (100 + 152.6) * 11.4$$

$$= 2{,}892.3 \text{ therms}$$

Example System Types	Indoor Insulation, Hot Water	Indoor Insulation, 5 psi Steam	Indoor Insulation, 65 psi Steam	Domestic Hot Water	Outdoor Insulation, Hot Water	Outdoor Insulation, 5 psi Steam	Outdoor Insulation, 65 psi Steam
Annual Energy Savings/ft							
Annual Gas Use, Base Case (therms/yr/ft)	2.46 (w/o reset) 5.15 (w/ reset heat) 6.78 (w/reset year)	4.73 (non recirc) 14.4 (recirc heat) 25.4 (recirc year)	5.5 (non recirc) 16.7 (recirc heat) 29.5 (recirc year)	6.76	9.37 (w/o reset) 22.5 (w/ reset heat) 33.5 (w/reset year)	13.6 (non recirc) 41.4 (recirc heat) 73.2 (recirc year)	17.1 (non recirc) 52.0 (recirc heat) 91.8 (recirc year)
Annual Gas Use, Measure case (therms/yr/ft)	0.46 (w/o reset) 1.05 (w/ reset heat) 1.48 (w/reset year)	0.43 (non recirc) 1.4 (recirc heat) 2.4 (recirc year)	0.6 (non recirc) 1.8 (recirc heat) 3.2 (recirc year)	1.73	0.3 (w/o reset) 0.7 (w/ reset heat) 1.1 (w/reset year)	0.4 (non recirc) 1.2 (recirc heat) 2.1 (recirc year)	0.6 (non recirc) 1.6 (recirc heat) 2.8 (recirc year)
Annual Gas Savings (therms/yr/ft)	2.0 (w/o reset) 4.1 (w/ reset heat) 5.3 (w/reset year)	4.3 (non recirc) 13.0 (recirc heat) 23.0 (recirc year)	4.9(non recirc) 14.9 (recirc heat) 26.3 (recirc year)	5.02	9.1 (w/o reset) 21.8 (w/ reset heat) 32.4 (w/reset year)	13.2 (non recirc) 40.2 (recirc heat) 71.1 (recirc year)	16.5 (non recirc) 50.4 (recirc heat) 89 (recirc year)
Elbows, Tees, Flanges, & Valves							
Number of Elbows	5	10	20	n/a	5	10	20
Number of Tees	5	10	20	n/a	5	10	20
Number of Flanges	5	10	20	n/a	5	10	20
Number of Valves	5	10	20	n/a	5	10	20
Annual Energy Savings							
Total Gas Savings (therms/yr)	39 (w/o reset) 80 (w/ reset heat) 104 (w/reset year)	478 (non recirc) 1,456 (recirc heat) 2,571 (recirc year)	1,072 (non recirc) 3,267 (recirc heat) 5,770 (recirc year)	502	930 (w/o reset) 2,832 (w/ reset heat) 4,211 (w/reset year)	2,112 (non recirc) 6,434 (recirc heat) 11,364 (recirc year)	3,635 (non recirc) 11,074 (recirc heat) 19,560 (recirc year)

Heat = heating season only, year = year round

Values below must be multiplied by the appropriate Thermal Regain Factor (TRF). All variables were the same except for hours of operation in the calculation of the default savings per foot for the various building types and applications as presented in the table below:

Savings Summary for Indoor pipe insulation by System Type and Building Type (Δtherms per foot) (continues for 3.5 pages)

Location	System Type	Building Type	Annual therm Savings per linear foot (therm /ft) (2" pipe / 1" insulation for hot water, 2" insulation for steam)

For insulation covering elbows and tees that connect straight pipe, a calculated surface area will be assumed based on the dimensions for fittings given by ANSI/ASME B36.19. The surface area is then converted to an equivalent length of pipe, that must be added to the total length of straight pipe to calculate total savings. Equivalent pipe lengths are given in 1" increments in pipe diameter for simplicity. In the case of pipe diameters in between full inch diameters, interpolation should be used to determine the equivalent length. The larger pipe sizes mostly apply to steam header piping, which has the most heat loss per foot.

Calculated Surface Areas of Elbows and Tees

Nominal Pipe Diameter	Calculated Surface Area (ft)	
	90 Degree Elbow[751]	Straight Tee[752]
1"	0.10	0.13
2"	0.41	0.39
3"	0.93	0.77
4"	1.64	1.21
5"	2.57	1.77
6"	3.70	2.44
8"	6.58	3.95
10"	10.28	5.98
12"	14.80	8.34

Equivalent Length of Other Components – Elbows and Tees (L_{oc})

Nominal Pipe Diameter	Equivalent Length of Other Components (ft)	
	90 Degree Elbow	Straight Tee
1"	0.30	0.38
2"	0.66	0.63
3"	1.01	0.84
4"	1.40	1.03

[751] Based on the dimensions for diameter, long radius, and short radius given by ANSI/ASME 36.19.
[752] Based on the center to face and diameter dimensions given by ANSI/ASME B36.19.

Nominal Pipe Diameter	Equivalent Length of Other Components (ft)	
	90 Degree Elbow	Straight Tee
5”	1.76	1.22
6”	2.13	1.41
8”	2.91	1.75
10”	3.65	2.13
12”	4.44	2.50

For insulation around valves or flanges, a surface area from ASTM standard C1129-12 will be assumed for 2” pipes. For 1” pipes, which weren’t included in the standard, a linear-trended value will be used. The surface area is then converted to an equivalent length of either 1” or 2” straight pipe that must be added to the total length of straight pipe to calculate total savings.

Calculated Surface Areas of Flanges and Valves

Valves

REVIEW DEADLINE: 1/1/2027

4.4.15 Single-Package and Split System Unitary Air Conditioners

DESCRIPTION

This measure promotes the installation of high-efficiency unitary air-, water-, and evaporatively-cooled air conditioning equipment, both single-package and split systems. Air conditioning (AC) systems are a major consumer of electricity and systems that exceed baseline efficiency requirements can significantly reduce energy consumption. This measure could apply to the replacing of an existing unit at the end of its useful life or the installation of a new unit in a new or existing building.

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is assumed to be a high-efficiency air-, water-, or evaporatively-cooled air conditioner that exceeds the energy efficiency requirements as prescribed by the program.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline equipment is assumed to be a standard-efficiency air-, water, or evaporatively-cooled air conditioner that meets the Code energy efficiency requirements (IECC or Code of Federal Regulations whichever is higher) in effect on the date of equipment purchase (if date is unknown, assume current Code minimum).

For Early Replacement programs, use the actual efficiency of the existing unit or assume IECC code base in place at the original time of existing unit installation. To qualify under the early replacement characterization, baseline equipment must meet these additional qualifications:

- The existing unit is operational when replaced or the existing unit would be operational with minor repairs.[753]

In order for this characterization to apply, the baseline equipment is assumed to meet the efficiency requirements within the IECC code in effect on the date of the building permit. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Note, IECC 2021 became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code. If evaluation determines the applicable version of code, given location and timing, isn't an appropriate baseline due to supply constraints, low compliance, or other issues, the previous iteration of code may be used through 2023.

IECC 2021 leverages new DOE testing methods and associated metrics. The following conversion factors are recommended for use if the efficient equipment is not rated under the new testing procedure but the stipulated baseline is:[754]

SEER2 = X * SEER

EER2 = X * EER

HSPF2 = X * HSPF

Where:

[753] Based on ComEd Small Business Trade Ally feedback. For units rated at less than 20 ton units, the cost of common repairs is under $2,000, significantly less than the cost of purchasing new equipment. Therefore, if the cost of repair is less than $2,000, it can be considered early replacement because customers would repair instead of replace a failed unit. Repair cost data was not available for units larger than 20 tons.

[754] Consortium for Energy Efficiency (CEE), Testing, Testing, M1, 2, 3, Transitioning to New Federal Minimum Standards, CEE Summer Program Meeting, August, 2022.

X	SEER2	EER2	HSPF2
Ducted	0.95	0.95	0.85
Ductless	1.00	1.00	0.90
Packaged	0.95	0.95	0.84

Note: new Federal Standards affecting heat pumps and air conditioning equipment became effective January 1, 2025.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years.[755]

For early replacement, the remaining life of existing equipment is assumed to be 5 years.[756]

DEEMED MEASURE COST

The incremental capital cost for this measure is based upon capacity and efficiency level (defined be CEE specifications),[757] as outlined in the following table:[758]

	Incremental cost ($/ton)	
Capacity	Up to and including CEE Tier 1 units	CEE Tier 2 and above
< 135,000 Btu/hr	$63	$127
135,000 Btu/hr to > 250,000 Btu/hr	$63	$127
250,000 Btu/hr and greater	$19	$38

For early replacement, the full cost of the installed unit should be used. If unknown use defaults below. The assumed deferred cost (after 5 years) of replacing existing equipment with a new baseline unit is also provided. This future cost should be discounted to present value using the real discount rate:

	Full Install Cost ($/ton)		
Capacity	Base Units	Up to and including CEE Tier 1 units	CEE Tier 2 and above
< 135,000 Btu/hr	$895	$958	$1,021
135,000 Btu/hr to > 250,000 Btu/hr	$762	$825	$889
250,000 Btu/hr and greater	$673	$691	$710

LOADSHAPE

Loadshape C03 - Commercial Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

[755] Measure Life Report: Residential and Commercial/Industrial Lighting and HVAC Measures, GDS Associates, Inc., June 2007.
[756] Assumed to be one third of effective useful life.
[757] CEE Commercial Unitary Air-conditioning and Heat Pumps Specification, which provides high efficiency performance specifications for single-package and split system unitary air conditioners.
[758] NEEP Incremental Cost Study (ICS) Final Report – Phase 3, May 2014.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)
= 91.3% [759]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)
= 47.8% [760]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Time of Sale:

For units with cooling capacities less than 65 kBtu/hr:

$$\Delta kWH = (kBtu/hr) * [\frac{1}{SEER2base} - \frac{1}{SEER2ee}] * EFLH$$

For units with cooling capacities equal to or greater than 65 kBtu/hr:

$$\Delta kWH = (kBtu/hr) * [\frac{1}{IEERbase} - \frac{1}{IEERee}] * EFLH$$

Early replacement:[761]

For units with cooling capacities less than 65 kBtu/hr:

For remaining life of existing unit (1st 5 years):

$$\Delta kWH = (kBtu/hr) * [\frac{1}{SEER2exist} - \frac{1}{SEER2ee}] * EFLH$$

For remaining measure life (next 10 years):

$$\Delta kWH = (kBtu/hr) * [\frac{1}{SEER2base} - \frac{1}{SEER2ee}] * EFLH$$

For units with cooling capacities equal to or greater than 65 kBtu/hr:

For remaining life of existing unit (1st 5 years):

$$\Delta kWH = (kBtu/hr) * [\frac{1}{IEERexist} - \frac{1}{IEERee}] * EFLH$$

NOTE: If the existing equipment age is such that IEER ratings are not available, EER may be substitued when necessary. In such instances both existing and efficient unit efficiencies should be specified in EER.

For remaining measure life (next 10 years):

$$\Delta kWH = (kBtu/hr) * [\frac{1}{IEERbase} - \frac{1}{IEERee}] * EFLH$$

[759] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[760] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[761] The two equations are provided to show how savings are determined during the initial phase of the measure (existing to efficient) and the remaining phase (new baseline to efficient). In practice, the screening tools used may either require a First Year savings (using the first equation) and then a "number of years to adjustment" and "savings adjustment" input which would be the (new base to efficient savings)/(existing to efficient savings).

Where:

kBtu/hr	= capacity of the cooling equipment actually installed in kBtu per hour (1 ton of cooling capacity equals 12 kBtu/hr)
$SEER2_{base}$	= Seasonal Energy Efficiency Ratio of the baseline equipment
	= SEER2 values from tables below, based on applicable Code on date of equipment purchase (if unknown assume current Code).
$SEER2_{ee}$	= Seasonal Energy Efficiency Ratio of the energy efficient equipment (actually installed)
$SEE2R_{exist}$	= Seasonal Energy Efficiency Ratio of the existing equipment
	= Actual, or assume Code base in place at the original time of existing unit installation
$IEER_{base}$	= Integrated Energy Efficiency Ratio of the baseline equipment. See table below based on applicable Code on date of equipment purchase (if unknown assume current Code).
$IEER_{ee}$	= Integrated Energy Efficiency Ratio of the energy efficient equipment (actually installed)
$IEER_{exist}$	= Integrated Energy Efficiency Ratio of the existing equipment
	= Actual, or assume Code base in place at the original time of existing unit installation
EFLH	= Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use

The rating conditions for the baseline and efficient equipment efficiencies must be equivalent.

Code of Federal Redulations (baseline effective 1/1/2025):[762]

Equipment type	Cooling capacity	Heating type	Efficiency level	Compliance date
Small Commercial Packaged Air Conditioning and Heating Equipment (Air-Cooled)	≥65,000 Btu/h and <135,000 Btu/h	Electric Resistance Heating or No Heating	IEER = 12.9 IEER = 14.8	1/1/2018 1/1/2023
		All Other Types of Heating	IEER = 12.7 IEER = 14.6	1/1/2018 1/1/2023
Large Commercial Packaged Air Conditioning and Heating Equipment (Air-Cooled)	≥135,000 Btu/h and <240,000 Btu/h	Electric Resistance Heating or No Heating	IEER = 12.4 IEER = 14.2	1/1/2018 1/1/2023
		All Other Types of Heating	IEER = 12.2 IEER = 14.0	1/1/2018 1/1/2023
Very Large Commercial Packaged Air Conditioning and Heating Equipment (Air-Cooled)	≥240,000 Btu/h and <760,000 Btu/h	Electric Resistance Heating or No Heating	IEER = 11.6 IEER = 13.2	1/1/2018 1/1/2023
		All Other Types of Heating	IEER = 11.4 IEER = 13.0	1/1/2018 1/1/2023
Small Commercial Package Air-Conditioning and Heating Equipment (Air-Cooled, 3-Phase, Split-System)	<65,000 Btu/h	All	SEER2 = 13.4	1/1/2025
Small Commercial Package Air-Conditioning and Heating Equipment (Air-Cooled, 3-Phase, Single-Package)	<65,000Btu/h	All	SEER2 = 13.4	1/1/2025

Condensing units, evaporatively cooled	≥ 135,000 Btu/h	—	—	13.5 EER 14.0 IEER	AHRI 365

For SI: 1 British thermal unit per hour = 0.2931 W.

a. Chapter 6 contains a complete specification of the referenced standards, which include test procedures, including the reference year version of the test procedure.

b. Single-phase, US air-cooled air conditioners less than 65,000 Btu/h are regulated as consumer products by the US Department of Energy Code of Federal Regulations DOE 10 CFR 430. SEER and SEER2 values for single-phase products are set by the US Department of Energy.

c. DOE 10 CFR 430 Subpart B Appendix M1 includes the test procedure updates effective 1/1/2023 that will be incorporated in AHRI 210/240—2023.

d. This table is a replica of ASHRAE 90.1 Table 6.8.1-1 Electrically Operated Unitary Air Conditioners and Condensing Units—Minimum Efficiency Requirements.

For example, a 5 ton air cooled split system with a SEER2 of 15 at an existing retail strip mall in Rockford would save:

ΔkWH = (60) * [(1/13.4) – (1/15)] * 697

= 333 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Time of Sale:

$$\Delta kW = (kBtu/hr) * (\frac{1}{EER2base} - \frac{1}{EER2ee}) * CF$$

Early Replacement:

For remaining life of existing unit (1st 5 years):

$$\Delta kW = (kBtu/hr) * [\frac{1}{EER2exist} - \frac{1}{EER2ee}] * CF$$

For remaining measure life (next 10 years):

$$\Delta kW = (kBtu/hr) * [\frac{1}{EER2base} - \frac{1}{EER2ee}] * CF$$

Where:

$EER2_{base}$ = Energy Efficiency Ratio of the baseline equipment

= EER values from tables above, based on applicable Code on date of equipment purchase (if unknown assume current Code). (For air-cooled units < 65 kBtu/hr, assume the following conversion from SEER to EER for calculation of peak savings:[763] EER = (-0.02 * $SEER^2$) + (1.12 * SEER))

$EER2_{ee}$ = Energy Efficiency Ratio of the energy efficient equipment. If the actual EER_{ee} is unknown, assume the conversion from SEER to EER for calculation of peak savings as above).

= Actual installed

$EER2_{exist}$ = Energy Efficiency Ratio of the existing equipment

= Actual, or assume Code base in place at the original time of existing unit installation

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [764]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [765]

[763] Based on Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder. Note this is appropriate for single speed units only.

[764] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[765] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

For example, a 5 ton air cooled split system with a SEER of 15 in Rockford would save:

ΔkW_{SSP} = (60) * [(1/11.4) – (1/12.3)] * 0.913

= 0.352 kW

REVIEW DEADLINE: 1/1/2029

4.4.16 Steam Trap Replacement or Repair

DESCRIPTION

The measure applies to the repair or replacement of steam traps in the failed open state that allow steam to escape the steam distribution system or return to the condensate receiver leading to increased steam generation. The measure is applicable to commercial applications, commercial HVAC (low pressure steam) including multifamily buildings, low pressure industrial applications, medium pressure industrial applications, and high-pressure industrial applications.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is a repaired or replaced steam trap that is no longer allowing excess steam to escape.

Customers must have steam traps in the failed open or leaking state to qualify for rebates. However, if a commercial customer opts to replace all traps without inspection, rebates and the savings are discounted to take into consideration the fact that some traps are being replaced that have not yet failed.

DEFINITION OF BASELINE EQUIPMENT

The baseline criterion is a faulty steam trap in the failed open or leaking state. No minimum leak rate is required. Any leaking or blow through trap can be repaired or replaced. If a commercial customer chooses to repair or replace all the steam traps at the facility without verification, the savings are adjusted. Savings for commercial full replacement projects are reduced by the percentage of traps found to be leaking on average from the studies listed. If an audit is performed on a commercial site, then the leaking and blowdown can be adjusted.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

For standard steam traps the life of this measure is 6 years.[766]

For Venturi steam traps the measure life is 20 years if replacing a faulty mechanical steam trap.[767] If replacing an operational mechanical steam trap, the measure life is 14 years, having been reduced by the six-year measure life established for standard steam traps. By applying this conservative approach of reducing the measure life by the full estimated useful life of the existing steam trap, there is no need to survey or produce an inventory of the age of existing steam traps.

Venturi steam traps do not contain any moving parts, and their manufacturers cite this feature for the reduced failure rate leading to longer operational life than mechanical steam traps. Venturi steam traps have been observed to operate in excess of 20 years.[768] Venturi steam traps also typically come with a 10-year warranty that can be extended up to 20 years. Therefore, savings may be claimed on a year-to-year basis for venturi steam traps undergoing annual maintenance that have exhausted their deemed 20-year measure life.

---

[766]Source paper is the CLEAResult "Steam Traps Revision #1" dated August 2011. Primary studies used to prepare the source paper include Enbridge Steam Trap Survey, KW Engineering Steam Trap Survey, Enbridge Steam Saver Program 2005, Armstrong Steam Trap Survey, DOE Federal Energy Management Program Steam Trap Performance Assessment, Oak Ridge National Laboratory Steam System Survey Guide, KEMA Evaluation of PG&E's Steam Trap Program, Sept. 2007. Communication with vendors suggested an inverted bucket steam trap life typically in the range of 5 - 7 years, float and thermostatic traps 4- 6 years, float and thermodynamic disc traps of 1 - 3 years.

[767] "Venturi Steam Trap – Functional Laboratory Study, GTI on behalf of Illinois utilities, Nicor Gas, Peoples Gas, and North Shore Gas, and on behalf of contributing utilities from other states, March 26, 2019. This report reflects phase 1 of an ongoing field study that will continue data collection to validate useful life and provide information on proper sizing in various end use applications. Additional data expected in 2021.

[768] Ibid. Based on reported age for venturi steam traps currently operating in the field.

DEEMED MEASURE COST

Actual measure costs, including survey and installation costs should be used where available. Default costs per trap are provided below to be used in addition to an estimate of survey and installation costs.

Steam System	Cost per trap[769] ($)
Commercial Dry Cleaners	$77
Commercial Heating (including Multifamily), low pressure steam	$77
Industrial Medium Pressure: 15 < psig < 30	$180
Steam Trap, Industrial Medium Pressure: 30 ≤ psig < 75	$223
Steam Trap, Industrial High Pressure: 75 ≤ psig < 125	$276
Steam Trap, Industrial High Pressure: 125 ≤ psig < 175	$322
Steam Trap, Industrial High Pressure: 175 ≤ psig < 250	$370
Steam Trap, Industrial High Pressure: 250 ≤ psig	$418

Algorithm

CALCULATION OF SAVINGS

ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure but should not be included in TRC tests to avoid double counting the economic benefit of water savings. These savings only apply to situations in which steam is lost from the steam system.

$$\Delta kWh_{water} = \Delta Water\ (gallons) \ / \ 1{,}000{,}000 \ * \ E_{water\ supply}$$

Where

$E_{water\ supply}$ = Water Supply Energy Factor (kWh/Million Gallons)

= 2,571[770]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

$$\Delta Therm = Sa * (Hv + Hs * (T_1 - T_{source})) * Hours * L \ / \ (100{,}000 * \eta_B)$$

Where:

Sa = Steam loss per leaking trap (lbs/hr)

[769] Ibid.

[770] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'. Note since the water loss associated with this measure is due to evaporation and does not discharge into the wastewater system, only the water supply factor is used here.

For systems used in space heating applications that operate at 5 psig or lower, use the following equation to calculate Sa[771]. The condensate return system pressure, P_2, will typically be atmospheric pressure, 14.696 psia.

$$Sa = 1519.3 * P_1 * D^2 * [(1/T_1) * (\gamma/(\gamma-1)) * ((P_2/P_1)^{(2/\gamma)} - (P_2/P_1)^{((\gamma+1)/\gamma))}]^{0.5} * A * FF$$

For all other steam systems and applications, use the following equation.

$$Sa = 24.24 * P_1 * D^2 * A * FF$$

Defaults are provided in table below if custom calculation is not performed.

Where:

1519.3 = Constant, $(s^2 * °R^{0.5})/(ft * hr)$

P_1 = Average steam trap inlet pressure (absolute, psia). If not available, use defaults provided in table below (note that defaults are provided in psig, not psia).

D = Diameter of orifice, inches. Actual value should be used wherever possible as this value has a significant impact on steam flowrate value.

T_1 = Temperature of Saturated Steam (°R)

$= 507.89 * P_1^{0.0962}$

Where:

507.89 = Constant, $°R*(in^2/lb_f)^{0.0962}$

γ = Heat Capacity Ratio (unitless)

$= 5.071 * 10^{-4} * P_1 + 1.332$

P_2 = Average steam trap outlet pressure (absolute psia). If unknown, assume atmospheric pressure, 14.696 psia.

A = Adjustment factor

= 50%,[772] all steam systems. This factor accounts for reduction in the maximum theoretical steam flow to the average steam flow (the Enbridge factor).

FF = Flow Factor. In addition to the Adjustment factor (A), an additional 50 percent flow factor adjustment is recommended for medium and high-pressure steam systems to address industrial float and thermostatic style traps where additional blockage is possible.

24.24 = Constant $lbm/(hr-psia-in^2)$

Default Steam Loss per Trap (Sa) are provided below for different system types:

[771] See "Derivation of Equation for Subsonic Compressible Flow through an Orifice and Supporting Calculations for Illinois TRM Steam Trap Measure" paper for more information.

[772] Enbridge adjustment factor used as referenced in CLEAResult "Work Paper Steam Traps Revision #2" Revision 3 dated March 2, 2012 and DOE Federal Energy Management Program Steam Trap Performance Assessment.

Steam System	Average Steam Trap Inlet Pressure (psig)[773]	Diameter of Orifice (in)	Adjustment Factor	Flow Factor	Average Actual Steam Loss per Leaking Trap (lbm/hr/trap) [774]
Commercial Dry Cleaners	82.8	0.1250	50%	100%	18.5
Multifamily LPS Space Heating – calculate Sa as provided above. If using default value, cap total savings at 20% of building consumption	-	-	50%	100%	6.9

Hs = Specfic heat of water, (Btu/(lbm * °R))

[773]Commercial and Industrial low pressure steam trap inlet pressure based on Franklin Energy and Opinion Dynamics analysis of data collected by Armstrong for 120,833 steam traps. Data covered coil, process, and radiator steam trap applications on modulating and constant pressure systems less than 15psi.
Medium and high pressure steam trap inlet pressure based on Navigant analysis of source collected during program implementation by Nicor Gas for GPY1 through GPY4. For each steam trap project, the data provided measure savings description, operating pressure, installation Zip code, business building type, program year, and annual operating hours. Dry cleaning steam trap inlet pressure based on C5 Steam Traps – Nicor FINAL 10.27.11.

[774] For applications where inlet pressures and orifice diameters are provided in the table, default values are directly calculated using the equation above. For the multifamily LPS space heating applications where inlet pressures and orifice diameters are not provided in the table, default values are assumptions based on engineering judgement and will be revisited in future years.

[775] Heat of vaporization of steam at the inlet pressure to the steam trap. Implicit assumption that the average boiler nominal pressure where the vaporization occurs, is essentially that same pressure. Referenced in CLEAResult "Work Paper Steam Traps Revision #2" Revision 3 dated March 2, 2012.

= 1.001

T_{source} = Incoming water temperature

= 513.67°R[776]

η_B = Boiler efficiency

= custom, if unknown:

= 79% for steam boilers[777]

Hours = Annual hours when steam system is pressurized

= custom, if unknown:

Steam System	Zone (where applicable)	Hours/Yr[778]
Commercial Dry Cleaners	All Climate Zones	2,425

	Chicago	4,029
	Springfield	3,406
	Belleville	2,515
	Marion	2,546
Multifamily Space Heating LPS	For steam traps that are part of steam systems where the boiler cycles on/off to maintain space setpoint temperature or for steam traps located downstream of a steam control valve that opens/closes to maintain setpoint temperature, use Heating EFLH values in Section 4.4 for High Rise or Mid-Rise MF buildings. For steam traps that are exposed to steam continuously throughout the heating season, use the values listed above for Commercial Space Heating LPS for your appropriate climate zone.	

L = Leaking & blow-thru

L is 1.0 when applied to the replacment of an individual leaking trap. If a number of steam traps are replaced and the system has not been audited, the leaking and blow-thru is applied to reflect the assumed percentage of steam traps that were actually leaking and need to be replaced. A custom value can be utilized if a supported by an evaluation.

[776] US DOE Building America Program. Building America Analysis Spreadsheet. For Chicago, IL.

[777] Federal Register, volume 74, Number 139, July 22, 2009 for boilers >300,000 Btu/hr

[778] Medium and high-pressure steam trap annual operating hours based on Navigant analysis of source collected during program implementation by Nicor Gas for GPY1 through GPY4. For each steam trap project, the data provided measure savings description, operating pressure, installation Zip code, business building type, program year, and annual operating hours.

Steam System	L (%)[779]
Custom	Custom
Commercial Dry Cleaners	27%
Commercial Heating (including Multifamily) LPS	27%
Industrial/Process Low Pressure: psig < 15	16%
Medium Pressure: 15 ≤ psig < 30	16%
Medium Pressure: 30 ≤ psig < 75	16%
High Pressure: 75 ≤ psig < 125	16%
High Pressure: 125 ≤ psig < 175	16%
High Pressure: 175 ≤ psig < 250	16%
High Pressure: 250 ≤ psig < 300	16%

For example, a commercial dry cleaning facility with the default hours of operation and boiler efficiency;

$$\Delta\text{Therms} = Sa * (Hv + Hs * (T_1 - T_{source})) * Hours * L / (100{,}000 * \eta_B)$$

T_1 $= 507.89 * P_1^{0.0962}$

$= 507.89 * (82.8 + 14.696)^{0.0962}$

$= 789.1°R$

ΔTherms = 18.5 lbs/hr/trap * (890 Btu/lb + 1.001 * (789.1°R - 513.7°R)) * 2,425hrs * 27%/(100,000 * 80.7%)

= 175.0 therms per trap

WATER IMPACT DESCRIPTIONS AND CALCULATION

The hourly water volume saved per each repaired or replaced leaking trap is calculated by dividing the "Average Actual Steam Loss per Leaking Trap (lbm/hr/trap)" by the density of water saved, 8.33 lbm/gal, that replaces the lost steam. The average actual steam loss is provided in the table for parameter *Sa*, the "Average actual steam loss per leaking trap" in the Fossil Fuel Savings section above. Annual water savings are calculated using *Hours* and *L*, the leaking and blow through factor, as defined above.

Water savings only apply to situations where condensate is lost from the steam system. If a condensate recovery system is in place, assume zero water savings or provide a custom calculation based on site-specific operation.

The annual water savings for a replaced or repaired trap is given by:

$$\Delta\text{Water} = GAL * Hours * L$$

Where:

GAL = average actual water volume saved per leaking trap, as listed in the following table and based on steam system type.

Other variables as defined above.

Steam System*	Average Actual Steam Loss per Leaking Trap (lbm/hr/trap)	GAL: Average Actual Water Volume Saved per Leaking Trap Atmospheric Venting (gal/hr/trap)
Commercial Dry Cleaners	18.5	2.22
Multifamily LPS Space Heating	6.9	0.83

[779]Dry cleaners survey data as referenced in CLEAResult "Work Paper Steam Traps Revision #2" Revision 3 dated March 2, 2012.

REVIEW DEADLINE: 1/1/2028

4.4.17 Variable Speed Drives for HVAC Pumps and Cooling Tower Fans

DESCRIPTION

This measure is applied to variable speed drives (VSD) which are installed on the following HVAC system applications: chilled water pump, hot water pumps and cooling tower fans. There is a separate measure for HVAC supply and return fans. All other VSD applications require custom analysis by the program administrator. The VSD will modulate the speed of the motor when it does not need to run at full load. Since the power of the motor is proportional to the cube of the speed for these types of applications, significant energy savings will result.

This measure is not applicable for:

- Cooling towers, chilled or hot water pumps with any process load.
- VSD installation in existing cooling towers with 2-speed motors. (current code requires 2-speed motors for cooling towers with motors greater than 7.5 HP)
- VSD installation in new cooling towers with motors greater than 7.5 HP

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The VSD is applied to a motor which does not have a VSD. This measure is not applicable for replacing failed VSDs. The application must have a variable load and installation is to include the necessary controls. Savings are based on application of VSDs to a range of baseline load conditions including no control, inlet guide vanes, outlet guide vanes and throttling valves.

DEFINITION OF BASELINE EQUIPMENT

The time of sale baseline is a new motor installed without a VSD or other methods of control. Retrofit baseline is an existing motor operating as is. Retrofit baselines may or may not include guide vanes, throttling valves or other methods of control. This information shall be collected from the customer.

Installations of new equipment with VSDs which are required by IECC, state energy code as adopted by the State of Illinois are not eligible for incentives. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Note, IECC 2021 became effective statewide as of 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to the 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for HVAC application is 15 years;[780] measure life for process is 15 years.[781]

DEEMED MEASURE COST

Customer provided costs will be used when available. Default measure costs[782] are noted below for up to 75 hp motors. Custom costs must be gathered from the customer for motor sizes not listed below.

[780] ComEd Effective Useful Life Research Report (2018), Navigant, May 14, 2018
[781] California Public Utilities Commission (CPUC), Energy Division. 2014. "DEER2014-EUL-table-update_2014-02-05.xlsx"
[782] NEEP Incremental Cost Study Phase Two Final Report dated January 13, 2013 (pg. 32; Table 15). Equipment and labor costs were extrapolated or interpolated as necessary for motor sizes not covered in the incremental cost study.

HP	Cost
5 HP	$2,250
7.5 HP	$2,517
10 HP	$2,784
15 HP	$3,318
20 HP	$3,852
25 HP	$4,386
50 HP	$6,573
75 HP	$8,532

Loadshape C49 - VFD Cooling Tower Fans <10 HP

COINCIDENCE FACTOR

The demand savings factor (DSF) is already based upon coincident savings, and thus there is no additional coincidence factor for this characterization.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = BHP\ /EFFi * Hours * ESF$$

Where:

BHP = System Brake Horsepower

(Nominal motor HP * Motor load factor)

Motors are assumed to have a load factor of 65% for calculating kW if actual values cannot be determined[783]. Custom load factor may be applied if known.

EFFi = Motor efficiency, installed. Actual motor efficiency shall be used to calculate kW. If not known, default motor is a NEMA Premium Efficiency, ODP, 4-pole/1800 RPM fan motor, as detailed in the table below.

[783] Del Balso, Ryan J. "Investigation into the Reliability of Energy Efficiency/Demand Side Management Savings Estimates for Variable Frequency Drives in Commercial Applications", University of Colorado, Department of Civil, Environmental and Architectural Engineering, 2013.

4.4.18 Small Commercial Programmable Thermostats – Retired 12/31/2019. Replaced with 4.4.48 Small Commercial Thermostats

4.4.19 Demand Controlled Ventilation

DESCRIPTION

Demand control ventilation (DCV) adjusts outside ventilation air based on the number of occupants and the ventilation demands that those occupants create. DCV is part of a building's ventilation system control strategy. It may include hardware, software, and controls as an integral part of a building's ventilation design. Active control of the ventilation system provides the opportunity to reduce heating and cooling energy use.

The primary component is a control sensor to communicate either directly with the economizer or with a central computer. The component is most typically a carbon dioxide (CO_2) sensor, occupancy sensor, or turnstile counter. This measure is applicable to multiple building types, and savings are classified by the specific building types defined in the Illinois TRM. This measure is modeled to assume night time set backs are in operation and minimum outside air is being used when the building is unoccupied. Systems that have static louvers or that are open at night will likely have greater savings by using the custom program.

Demand controlled ventilation controls can also be added to the exhaust fans to enclosed parking garages. The fans modulate the ventilation airflow based on pollutant concentrations (primarily carbon monoxide) in the space.

This measure does not apply to packaged single-zone (PSZ) rooftop units with functioning economizers. For PSZ with functioning economizers, see 4.4.41 Advanced Rooftop Controls.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment condition is defined by new CO_2 sensors installed on return air systems where no other sensors were previously installed. For heating savings, this measure does not apply to any system with terminal reheat (constant volume or variable air volume). For terminal reheat system a custom savings calculation should be used.

DEFINITION OF BASELINE EQUIPMENT

The base case for this measure is a space with no demand control capability. The current code minimum for outside air (OA) is 5 CFM per occupant (ASHRAE 62.1 - 2016) which is the value for office space assumed in this measure.

This measure does not apply to packaged single-zone (PSZ) rooftop units with functioning economizers. For PSZ with functioning economizers, see 4.4.41 Advanced Rooftop Controls.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The deemed measure life is 10 years and based on CO_2 sensor estimated life. [788]

DEEMED MEASURE COST

The deemed measure cost is assumed to be the full cost of installation of a DCV retrofit including sensor cost ($278) and RTU integration cost($900per zone) for a total of $1,178.[789]

[788] During conversations with vendors and Building Automation System (BAS) contractors, it was determined that sensors must be functional for up to 10 years. It is recommended that they are part of a normal preventive maintenance program in which calibration is an important part of extending useful life. Although they are not subject to mechanical failure, they do fall out of tolerance over time.

[789] Business Energy Advisor | Demand-Controlled Ventilation (bizenergyadvisor.com), 2017. Average sensor cost used from list of eight different vendors and CO2 sensors. RTU integration costs assume high end of estimated range ($300-$900) for implementing DCV on a newer DCV-ready RTU with existing economizer.

Adding demand controlled ventilation to parking garages is assumed to cost $500 per sensor including the cost of the controller. The installation cost is estimated at $1,000 for labor.[790]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

For facilities heated by natural gas,

$$\Delta kWh = Condition\ Space/1000 * SF_{cooling}$$

For facilities heated by heat pumps,

$$\Delta kWh = Condition\ Space/1000 * SF_{cooling} + Condition\ Space/1000 * SF_{Heat\ HP}$$

For facilities heated by electric resistance,

$$\Delta kWh = Condition\ Space/1000 * SF_{cooling} + Condition\ Space/1000 * SF_{Heat\ ER}$$

Where:

Conditioned Space = actual square footage of conditioned space controlled by sensor

$SF_{cooling}$ = Cooling Savings Factor

= value in table below based on building type and weather zone

$SF_{Heat\ HP}$ = Heating Savings factor for facilities heated by Heat Pump (HP)

= value in table below based on building type and weather zone

$SF_{Heat\ ER}$ = Heating Savings factor for facilities heated by Electric Resistance (ER)

= value in table below based on building type and weather zone

Saving Factor Tables[791]

[790] California Utilities Statewide Codes and Standards Team. 2011. "2013 California Building Energy Efficiency Standards", Garage Exhaust, Section 4.2 Page 14.

[791] The electric energy savings was calculated using TMY3 weather data and methodology consistent with ASHRAE standards. Savings are calculated on an annual basis for each given temperature zone in Illinois. Energy savings for DCV were developed utilizing standards, inputs and approaches as set forth by ASHRAE 90.1 -2010 (code level up until Dec 31, 2015). Building input parameters like square footage, equipment efficiencies and occupancy match those used in the EFLH calculations. Reference calculation found in Demand Control Ventilation 12-30-13.xls.

[793] The natural gas energy savings was calculated using TMY3 weather data and methodology consistent with ASHRAE standards. Savings are calculated on an annual basis for each given temperature zone in Illinois. Energy savings for DCV were developed utilizing standards, inputs and approaches as set forth by ASHRAE 62.1 and 90.1, respectively. Building input parameters like square footage, equipment efficiencies and occupancy match those used in the EFLH calculations. Reference calculation found in Demand Control Ventilation 12-30-13.xls.

For example, for a 7500 SqFt of low-rise office space in Chicago.

ΔTherms = 7,500/1,000 * 26

= 195 Therms

4.4.20 High Turndown Burner for Space Heating Boilers

DESCRIPTION

This measure is for a non-residential boilers equipped with linkageless controls providing space heating with burners having a turndown less than 6:1.[794] Turndown is the ratio of the high firing rate to the low firing rate. When boilers are subjected to loads below the low firing rate, the boiler must cycle on/off to meet the load requirements. A higher turndown ratio reduces burner startups, provides better load control, saves wear-and-tear on the burner, and reduces purge-air requirements, all of these benefits result in better overall efficiency.

This measure was developed to be applicable to the following program types: NC, TOS, RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify the boiler linkageless burner must operate with a turndown greater than or equal to 10:1 and be subjected to loads less than or equal to 30% of the full fire input MBH[795] for greater than 60% of the operating hours.[796]

DEFINITION OF BASELINE EQUIPMENT

The baseline boiler utilizes a linkageless burner with a turndown ration of 6:1 or less and is used primarily for space heating. Redundant boilers do not qualify. Code requirements must be considered.

Note: beginning with the 2015 edition, and continuing through the 2021 edition, IECC makes the following requirements for boiler turndown:

Boiler Systems with design input of greater than 1,000,000 Btu/h shall comply with the turndown ratio specified in the following table.

The system turndown requirement shall be met through the use of multiple single-input boilers, one or more *modulating boilers* or a combination of single-input and *modulating boilers*.

BOILER SYSTEM DESIGN INPUT	MINIMUM TURNDOWN RATIO
≥ 1,000,000 and less than or equal to 5,000,000	3 to 1
> 5,000,000 and less than or equal to 10,000,000	4 to 1
> 10,000,000	5 to 1

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be the lower of remaining useful life of the boiler, or 21 years.[797]

DEEMED MEASURE COST

Actual costs shall be used as available. When unknown, the deemed installed measure cost including labor is approximately $2.53/MBtu/hr.[798]

4.4.21 Linkage-less Boiler Controls for Space Heating

DESCRIPTION

This measure is for a non-residential boiler providing space heating with single-point positioning combustion control. In single-point positioning control, the fuel valve is linked to the combustion air damper via a jackshaft mechanism to maintain correspondence between fuel and combustion air input. Most boilers with single-point positioning control do not maintain low excess air levels over their entire firing range. Generally, these boilers are calibrated at high fire, but due to the non-linearity required for efficient combustion, excess air levels tend to dramatically increase as the firing rate decreases. Boiler efficiency drops as the excess air levels are increased.

This measure was developed to be applicable to the following program types: TOS, NC, RF.
If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify the boiler burner must have a linkage-less control system allowing the combustion air damper position to be adjusted and set for optimal efficiency at several firing rates throughout the burner's firing range. This requires the fuel valve and combustion air damper to each be powered by a separate actuator. An alternative to the combustion air damper is a Variable Speed Drive on the combustion air fan. Note: this measure only applies to the incremental savings attributed to linkage-less positioning. If O_2 trim is installed, also see measure 4.4.22 "Oxygen Trim Controls for Space Heating Boilers".

DEFINITION OF BASELINE EQUIPMENT

The baseline boiler utilizes single-point positioning for the burner combustion control.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years.[804]

DEEMED MEASURE COST

The deemed measure cost is estimated at $8,500.[805]

FOSSIL FUEL SAVINGS

$$\Delta\text{Therms} = Ngi * SF * EFLH / 100$$

Where:

Ngi = Boiler gas input size (kBtu/hr) = custom

SF = Savings factor

Note: Savings factor is the percentage increase in efficiency as a result of the added linkage-less burner controls. Across all boiler firing rates, single-point controls are assumed to have an average of 57% excess airwhile linkage-less controls are assumed to have 27% excess air.[806] The difference between controls types is 30% under this operating condition. A 15% reduction in excess air is approximately a 1% increase in efficiency.[807] Therefore the nominal combustion efficiency increase is 30 / 15 * 1% = 2.0%.

= 2.0%

[806] ACEEE Summer Study 2008, Common Boiler Excess Air Trends and Strategies to Optimize Efficiency. Excess air value is an average of high/med/low firing rates for all three test cases provided, which ranged from a low of 24% at high-fire, to a high of 115% at low-fire. Linkage-less excess air percentage was taken from the average of firing rates from the test case provided.

[807] Department of Energy (DOE). January 2012, Steam Tip Sheet #4, Improve Your Boiler's Combustion Efficiency. Advanced Manufacturing Office. Washington, DC: U.S. Department of Energy. This value was determined as an appropriate average over the stack temperatures and excess air levels indicated.

4.4.22 Oxygen Trim Controls for Space Heating Boilers

DESCRIPTION

This measure is for a non-residential boiler providing space heating without oxygen trim combustion controls. Oxygen (O_2) trim controls limit the amount of excess oxygen provided to the burner for combustion. This oxygen level is dependent upon the amount of air provided. Oxygen trim control converts parallel positioning, linkage-less controls, into a closed-loop control configuration with the addition of an exhaust gas analyzer and PID controller. Boilers with oxygen trim controls can maintain a predetermined excess air rate (generally 15% to 30% excess air) over the entire burner firing rate. Boilers without these controls typically have excess air rates around 30% over the entire firing rate. Boiler efficiency drops as the excess air levels are increased.

This measure was developed to be applicable to the following program types: NC, TOS, RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify the boiler burner must have an oxygen control system allowing the combustion air to be adjusted to maintain a predetermined excess oxygen level in the flue exhaust at all firing rates throughout the burner's firing range. This requires an oxygen sensor in the flue exhaust and linkage-less fuel valve and combustion air controls.

DEFINITION OF BASELINE EQUIPMENT

The baseline boiler utilizes linkage-less positioning for the burner combustion control. For boilers with single-point positioning control, see measure 4.4.21 "Linkage-less boiler controls for Space Heating". This measure is intended as an incremental upgrade to linkage-less controls.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for the O_2 Trim controls is 20 years.[808]

DEEMED MEASURE COST

Custom costs should be used when available. The default measure cost is approximately $17,400.[809]

4.4.23 Shut Off Damper for Space Heating Boilers or Furnaces

DESCRIPTION

This measure is for non-residential atmospheric boilers or furnaces providing space heating without a shut off damper. When appliances are on standby mode warm room air is drawn through the stack via the draft hood or dilution air inlet at a rate proportional to the stack height, diameter and outdoor temperature. More air is drawn through the vent immediately after the appliance shuts off and the flue is still hot. Installation of a new shut off damper can prevent heat from being drawn up the warm vent and reducing the amount of air that passes through the furnace or boiler heat exchanger. This reduction in air can slightly increase overall operating efficiency by reducing the time needed to achieve steady-state operating conditions.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify the space heating boiler or furnace must have a new electrically or thermally activated shut off damper installed on either the exhaust flue or combustion air intake. Barometric dampers do not qualify. The damper actuation shall be interlocked with the firing controls.

DEFINITION OF BASELINE EQUIPMENT

The baseline boiler or furnace incorporates no shut off damper on the combustion air intake or flue exhaust.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for the shut off damper is 15 years,[814] or for the remaining lifetime of the heating equipment, whichever is less.

DEEMED MEASURE COST

Given the variability in cost associated with differences in system specifications and design, as well as choice of measure technology, actual installed costs should be used as available or based on program-specific qualification requirements. When unavailable, a deemed measure cost of $1,500 shall be assumed.[815]

4.4.24 Small Pipe Insulation

DESCRIPTION

This measure provides rebates for adding insulation to bare pipes with inner diameters of ½" and ¾". Insulation must be at least one inch thick. Since new construction projects are required by code to have pipe insulation, this measure is only for retrofits of existing facilities. This covers bare straight pipe as well as all fittings.

Default savings are provided on a per linear foot basis. It is assumed that the majority of pipes less than one inch in commercial facilities are used for domestic hot water. However, this measure can cover hydronic heating systems as well as low and high pressure steam systems.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is a ½"or ¾" diameter pipe with at least one inch of insulation. Insulation must be protected from damage which includes moisture, sunlight, equipment maintenance and wind. Outdoor pipes should have a weather protective jacket. Insulation must be continuous over straight pipe, elbows and tees.

DEFINITION OF BASELINE EQUIPMENT

The base case for savings estimates is a bare hot water or steam pipe with a fluid temperature of 105 degrees Fahrenheit or greater. Current new construction code requires insulation amounts similar to this measure, though this base case is commonly found in older existing buildings.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 15 years.[818]

DEEMED MEASURE COST

The incremental measure cost for insulation is the full cost of adding insulation to the pipe. Actual installation costs should be used for the measure cost. For planning purposes, the following costs can be used to estimate the full cost of materials and labor.[819]

Insulation Thickness	¾" pipe	½" pipe
1"	$4.45	$4.15

TRF = Thermal Regain Factor for pipe location and use, see table below. The Custom TRF option may be used on any pipe location, including pipe locations with deemed TRFs

[820] This value comes from the reference table "Savings Summary by Building Type and System Type." The formula and the input tables in this section document assumptions used in calculation spreadsheet "Pipe Insulation Savings 2013-11-12.xlsx".

[821] Federal Register, volume 74, Number 139, July 22, 2009 for boilers >300,000 Btu/hr

[822] Ibid.

specifically listed in the table below, if supporting justification and calculations for the Custom TRF are provided.

May vary seasonally such as: TRF[summer] * summer hours + TRF[winter] * winter hours where TRF values reflecting summer and winter conditions are apportioned by the hours for those conditions. TRF may also be adjusted by building specific balance point temperature (BPT) and operating hours above and below that BPT.[823]

Pipe Location	Assumed Regain	TRF, Thermal Regain Factor
Outdoor	0%	1.0
Indoor, conditioned space during the heating season, 55°F BPT	85%	0.15
Indoor, conditioned space, not during the heating season, 55°F BPT	0%	1.0
Indoor, conditioned, annual use (e.g. hot water or process loads), 55°F BPT	45%	0.55
Indoor, semi- conditioned, (unconditioned space, with heat transfer to conditioned space. E.g., boiler room, ceiling plenum, basement, crawlspace, wall), during the heating season, 55°F BPT	30%	0.70
Indoor, semi-conditioned, not during the heating season, 55°F BPT	0%	1.0
Indoor, semi-conditioned, annual use, 55°F BPT	16%	0.84
Indoor, unconditioned spaces, (no heat transfer to conditioned space)	0%	1.0
Location not specified - Commercial	23%	0.77
Location not specified – Industrial	16%	0.84
Custom	Custom	1 – assumed regain

L_{sp} = Length of straight pipe to be insulated (linear foot)

$L_{oc,i}$ = Total equivalent length of (elbows and tees) of pipe to be insulated. Use table below to determine equivalent lengths.

Nominal Pipe Diameter	Equivalent Length (ft)	
	90 Degree Elbow	Straight Tee
1/2"	0.04	0.03
3/4"	0.06	0.05

The table below shows the deemed therm savings by building type and region on a per linear foot basis for both ½" and ¾" copper pipe.

The following table provides deemed values for 1/2" copper pipe, temperatures are assumed by category below, and insulation is assumed to be one inch fiberglass.

[823] Zimmerman, Cliff, Franklin Energy, "Thermal Regain Factor_4-30-14.docx", 2014. Based on climate zone 2. Note 'Location not specified – Commercial' assumes semi-conditioned spaces with 50% pipes providing space heating and 50% providing DHW. 'Location not specified – Commercial' assumes semi-conditioned annual usage.

MEASURE CODE: CI-HVC-SPIN-V05-260101

REVIEW DEADLINE: 1/1/2027

4.4.25 Small Commercial Programmable Thermostat Adjustments – Retired 12/31/2019.

4.4.26 Variable Speed Drives for HVAC Supply and Return Fans

DESCRIPTION

This measure is applied to variable speed drives (VSD) which are installed on HVAC supply fans and return fans. The VSD will modulate the speed of the motor when it does not need to run at full load. Since the power of the motor is proportional to the cube of the speed for these types of applications, significant energy savings will result.

Note this measure should be used for evaluating control system modifications. If combined with the evaluation of a more efficient over a baseline fan, measure '4.4.53 HVAC Supply, Return and Exhaust Fans – Fan Energy Index' should be utilized. The FEPnew value from measure 4.4.53 should be used to replace the $\left(0.746 \times HP \times \frac{LF}{\eta_{motor}}\right)$ term in this measure.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The VSD is applied to a motor which does not have a VSD. The application must have a variable load and installation is to include the necessary controls. Savings are based on application of VSDs to a range of baseline load conditions including no control, inlet guide vanes, outlet guide vanes and throttling valves.

DEFINITION OF BASELINE EQUIPMENT

The time of sale baseline is a new motor installed without a VSD or other methods of control. Retrofit baseline is an existing motor operating as is. Retrofit baselines may or may not include guide vanes, throttling valves or other methods of control. This information shall be collected from the customer.

Installations of new equipment with VSDs which are required by IECC, state energy code as adopted by the State of Illinois are not eligible for incentives. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Note, IECC 2021 became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for all VSDs is 15 years.[824]

DEEMED MEASURE COST

Customer-provided costs will be used when available. Default measure costs are noted below for up to 75 hp motors.[825] Custom costs must be gathered from the customer for motor sizes not listed below.

HP	Cost
5 HP	$2,585
15 HP	$4,483
25 HP	$6,524
50 HP	$11,239
75 HP	$15,834

LOADSHAPE

Loadshape C39 - VFD - Supply fans <10 HP

Loadshape C40 - VFD - Return fans <10 HP

Loadshape C41 - VFD - Exhaust fans <10 HP

[824] Efficiency Vermont TRM 10/26/11 for HVAC VSD motors.

[825] RS Means, 2023. Equipment and labor costs for new VSD installation in Springfield, IL .

COINCIDENCE FACTOR

The demand savings factor (DSF) is already based upon coincident savings, and thus there is no additional coincidence factor for this characterization.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS[826]

kWh_{Base} = $$\left(0.746 \times HP \times \frac{LF}{\eta_{motor}}\right) \times RHRS_{Base} \times \sum_{0\%}^{100\%} (\%FF \times PLR_{Base})$$

$kWh_{Retrofit}$ = $$\left(0.746 \times HP \times \frac{LF}{\eta_{motor}}\right) \times RHRS_{base} \times \sum_{0\%}^{100\%} (\%FF \times PLR_{Retrofit})$$

ΔkWh_{fan} = $$\mathrm{kWh_{Base}} - \mathrm{kWh_{Retrofit}}$$

ΔkWh_{total} = $$\Delta\mathrm{kWh_{fan}} \times (1 + \mathrm{IE_{energy}})$$

Where:

kWh_{Base} = Baseline annual energy consumption (kWh/yr)

$kWh_{Retrofit}$ = Retrofit annual energy consumption (kWh/yr)

ΔkWh_{fan} = Fan-only annual energy savings

ΔkWh_{total} = Total project annual energy savings

0.746 = Conversion factor for HP to kWh

HP = Nominal horsepower of controlled motor

LF = Load Factor; Motor Load at Fan Design CFM (Default = 65%)[827]

η_{motor} = Installed nominal/nameplate motor efficiency

Default motor is a NEMA Premium Efficiency, ODP, 4-pole/1800 RPM fan motor

[826] Methodology developed and tested in Del Balso, Ryan Joseph. "Investigation into the Reliability of Energy Efficiency/Demand Side Management Savings Estimates for Variable Frequency Drives in Commercial Applications". A project report submitted to the Faculty of the Graduate School of the University of Colorado, 2013.

4.4.27 Energy Recovery Ventilator

DESCRIPTION

This measure includes the addition of energy recovery equipment on existing or new unitary equipment, where energy recovery is not required by the IECC 2012/2015/2018/2021. This measure analyzes the heating and cooling savings potential from recovering energy from exhaust or relief building air. This measure assumes that during unoccupied hours of the building no exhaust or relief air is available for energy recovery.

This measure was developed to be applicable to the following program types: TOS, NC, RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Efficient equipment is unitary equipment that incorporates energy recovery not required by the IECC 2012/2015/2018/2021.

DEFINITION OF BASELINE EQUIPMENT

The baseline is unitary equipment not required by IECC 2012/2015/2018/2021 to incorporate energy recovery.

Note, IECC 2021 became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for the domestic energy recovery equipment is 15 years.[830]

DEEMED MEASURE COST

The incremental cost for this measure assumes cost of cabinet and controls incorporated into packaged and built up air handler units. Additionally, it assumes a 1 to 1 ratio of fresh and exhausted air.

Energy Recovery Equipment Type	Incremental Cost $/CFM[831]
Plate Heat Exchanger	$3.75
Rotary Wheel	$3.75

DEEMED O&M COST ADJUSTMENTS

There are no expected O&M savings associated with this measure.

Algorithm

CALCULATION OF ENERGY SAVINGS ELECTRIC ENERGY SAVINGS

The electric energy savings calculation here represents the net electric energy savings from reduced cooling requirements after accounting for increased fan power caused by additional pressure drop from the ERV device. These savings do not account for heating energy savings in HVAC systems using heat pumps or electric resistance heat. This calculation does not apply to sensible-only devices such as heat pipes.

ΔkWh = $(cfm) * Normalized\ Electric\ Energy\ Savings$

cfm = design supply air flow of energy recovery ventilator in cubic feet per minute

= rated energy recovery ventilator supply air flow * (1 – Exhaust Air Transfer Ratio)

Exhaust Air Transfer Ratio = percentage of supply air made up of cross-leakage from exhaust air; value provided by vendor

= 0.05 (default)

Normalized Electric Energy Savings

= kWh/cfm savings value for the expected energy savings (net of fan energy penalty) as detailed in Table 1 – Electric Energy Savings Summary (kWh/cfm)

Table 1 – Electric Energy Savings Summary (kWh/cfm)[832]

Building Type	Normalized Electricity Savings (kWh/OA cfm)				
	Zone 1 - Rockford	Zone 2 - Chicago	Zone 3 - Springfield	Zone 4 - Mt. Vernon/Belleville	Zone 5 - Marion

FOSSIL FUEL SAVINGS

Gas savings algorithm is derived from the following:

ΔTherms $=(Design\ Heating\ Load * TE_ERV * EFLH * OccHours/24) / (100{,}000 * \eta Heat)$

Where:

Design Heating Load = (1.08 * CFM * ΔT)

1.08 = A constant for sensible heat equations (BTU/h/CFM.°F)

CFM = Cubic Feet per Minute of Energy Recovery Ventilator

ΔT = T_RA – T_DD

T_RA = Temperature of the Return Air = 70°F or custom

[833] Demand savings modeled using IL TRM energy models with added energy recovery wheels or enthalpy plates. Energy recovery device specifications based on product data from the AHRI Certification Directory (https://www.ahridirectory.org/Search/SearchHome?ReturnUrl=%2f). Coincident demand measured according to TRM guidelines, though in 1-hour increments as established by the eQUEST simulation.

T_DD = Temperature on design day of outside air[834]

= (see Table below) or custom

Zone	Weather Station	T_DD, Temperature, °F
1	Greater Rockford	-5.4
2	Chicago/O'Hare ARPT.	-1.0

4.4.28 Stack Economizer for Boilers Serving HVAC Loads

MEASURE DESCRIPTION

Stack economizers are designed to recover heat from hot boiler flue gasses. Recovered heat is used to preheat boiler feed water. This measure describes the retrofit of HVAC boilers with stack economizers. HVAC boilers are defined as those used for space heating applications. There is another, similar measure for boilers that serve process loads.

This measure was developed to be applicable to the following program types: NC, TOS, RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify the economizer must be installed on a boiler exhaust stack. Heat captured by the economizer is to be used to pre-heat boiler feed water.

DEFINITION OF BASELINE EQUIPMENT

The baseline boiler does not have an economizer installed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be the lower of the remaining useful life of the boiler or 15 years.[836]

DEEMED MEASURE COST

The incremental and full measure cost for this measure is custom.

DEEMED O&M COST ADJUSTMENTS

The O&M cost for this measure is custom.

4.4.30 Notched V Belts for HVAC Systems

MEASURE DESCRIPTION

This measure is for replacement of smooth v-belts in non-residential package and split HVAC systems with notched v-belts or for installing new equipment with synchronous belts instead of smooth v-belts. Typically there is a v-belt between the motor and the supply air fan and/or return air fan in larger package and split HVAC systems (RTU).

In general there are two styles of grooved v-belts, notched and synchronous. The DOE defines each as follows;

Notched V-Belts - A notched belt has grooves or notches that run perpendicular to the belt's length, which reduces the bending resistance of the belt. Notched belts can use the same pulleys as cross-section standard V-belts. They run cooler, last longer, and are about 2% more efficient than standard V-belts.

Synchronous Belts - Synchronous belts (also called cogged, timing, positive-drive, or high-torque drive belts) are toothed and require the installation of mating grooved sprockets. These belts operate with a consistent efficiency of 98% and maintain their efficiency over a wide load range.

- Smooth v-belts are usually referred to in five basic groups:
- "L" belts are low end belts that are for small, fractional horsepower motors and these are not used in RTUs.
- "A" and "B" belts are the two types typically used in RTUs. The "A" belt is a ½ inch width by 5/16 inch thickness and the "B" belt is larger, 21/32 inch wide and 12/32 inch thick so it can carry more power. V-belts come in a wide variety of lengths where 20 to 100 inches is typical.
- "C" and "D" belts are primarily for industrial applications with high power transmission requirements.
- V-belts are provided by various vendors. The notched version of these belts typically have an "X" added to the designation. For this HVAC fans notched v-belt Replacement measure, only the "A" and "B" v-belts are considered. A typical "A" v-belt is replaced by a notched "AX" v-belt and a "B" is replaced by a "BX." In general, smooth v-belts have an efficiency of 90% to 98% while notched v-belts have an efficiency of 95% to 98%. Because notched v-belts are more flexible they work with smaller diameter pulleys and they have less resistance to bending. Lower bending resistance increases the power transmission efficiency, lowers the waste heat, and allows the belt to last longer than a smooth belt.

Three research papers[853] [854] [855] show that the notched v-belt efficiency is 2% to 5% better than a typical smooth v-belt. A fourth paper by USDOE's Energy Efficiency and Renewable Energy[856] group reviewed most of the earlier literature and recommended using a conservative 2% efficiency improvement for energy savings for calculations.

For this measure it is assumed that upgrading a standard smooth v-belt with a new notched v-belt will result in a fan energy reduction of 2%.

DEFINITION OF EFFICIENT EQUIPMENT

For the Notched V-Belt characterization to apply, the Efficient Equipment is HVAC RTUs that have notched v-belts installed on the supply and/or return air fans. This can be done as a retrofit, TOS, or NC project.

For the Synchronous Belt characterization to apply, the Efficient Equipment is HVAC RTUs that have synchronous belts installed on the supply and/or return air fans. This can be done as a TOS or NC project. Retrofit projects can also claim savings, but costs should be verified independently (typically the cost of installing synchronous belts as a retrofit is not economically viable).

[853] "Gates Corporation Announces New EPDM Molded Notch V-Belts," The Gates Rubber Co., June 2010 (Assumed 3% efficiency improvement).
[854] "Synchronous Belt Drives Offer Low Cost Energy Savings," Baldor. February 2009. (attached in Reference Documents).
[855] "Energy Savings from Synchronous Belts," The Gates Rubber Co., February 2014. (Assumed 5% efficiency improvement).
[856] "Motor System Tip Sheet #5, Replace V-Belts with Cogged or Synchronous Belt Drives," USDOE-EERE, September 2005. (Assumed 2% efficiency improvement).

DEFINITION OF BASELINE EQUIPMENT

The Baseline Equipment is HVAC RTUs that have smooth v-belts installed on the supply and/or return air fans (i.e., RTU does not already have a notched v-belt installed).

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

A v-belt has a life based on fan run hours which varies by building type based primarily on occupancy schedule because the fans are required by code to operate continuously during occupied hours. The supply and return fans will also run a few hours during unoccupied hours for heating and cooling as needed. For the notched v-belt EUL calculation, the default hours in the following table are used for a variety of building types and HVAC applications.[857]

EUL = Belt Life / Occupancy Hours per year

Where:

Belt Life = 24,000 hours[858]

Occupancy Hours per year = values from Table below

The notched v-belt measure EUL is summarized by building type in the following table.

Notched v-belt Effective Useful Life (EUL)

Building Type	Total Fan Run Hours	EUL (Years)	Model Source

The lifetime of a synchronous belt system is the same as the lifetime of the equipment it is installed on because it is a permanent upgrade, involving the installation of toothed pulleys. Typical HVAC RTU lifetime is 15 years, which applies to synchronous belts as well. This is not to suggest that the actual belt component has an equivalent lifetime because they do require replacement. However, their O&M cost savings (derived from not having to tension, etc.) are assumed to offset the replacement cost of the belt, resulting in a net cost of zero. As a result, neither a separate lifetime nor O&M savings are quantified for synchronous belts and lifetime can therefore be considered as the lifetime of the equipment they're installed on because it would not be possible to install a traditional or notched belt on the synchronous pulleys.

DEEMED MEASURE COST

Costs of belts and pulleys are known to vary substantially based on belt length and pulley diameter. Two cost estimations are provided below; a fully deemed approach for applications such as an upstream program where limited information is known, and a semi-custom approach that is useful when more accurate cost estimates are desired.

Fully Deemed:

A review of the Grainger online pricing for "A," "B," "AX," and "BX" v-belts[859] revealed the incremental costs to upgrade to notched v-belts as summarized in the table below:

Notched V-belt Incremental Cost Summary

Smooth V-Belt Industry Number	Outside Length (Inches)	Dayton Smooth V-Belt*	Notched V-belt Industry Number	Dayton Notched v-belt*	Price Increase	% Increase
A30 (Item # 1A095)	32	$10.38	AX30 (Item # 3GWU4)	$14.64	$4.26	41%
B29 (Item # 6L208)	32	$14.38	BX29 (Item # 5TXL4)	$20.80	$6.42	45%
* Pricing based on Dayton Belts as found on Grainger Website 10/30/14						

Note that the incremental cost for notched V-Belts assumes that the notched belt is purchased and installed instead of a smooth v-belt. There is no difference in the cost of installation, only the material.

Synchronous Belt Incremental Cost Summary

Smooth V-Belt Industry Number	Smooth belt system Price*	Synchronous Belt Industry Number	Synchronous System Price*	Price Difference
Belt A30 (Item # 1A095)	$10.38	Belt 1DHL5 (Item # 322L050)	$15.37	$4.99

[859] Grainger catalog on-line web-site for Dayton v-belt pricing.

Smooth V-Belt Industry Number	Smooth belt system Price*	Synchronous Belt Industry Number	Synchronous System Price*	Price Difference
Gearbelt pulley BK47 (Item #5UHD5)	$47.98	Gearbelt sprocket GTR-36G-8M-12 (Item # 2UWH6)	$113.91	$65.93
* Costs based on Grainger pricing.				

Incremental cost for a NC or TOS project is $136.85. This is the price of synchronous equipment (belt, two sprockets) subtract v-belt equipment (belt, two pulleys). Labor cost is assumed to be equal in the baseline and efficient cases.

Incremental cost for a RF project is $380.49. This is the price of synchronous equipment and labor to install it[860] (not including a trip charge), less the cost of the v-belt (but not the pulleys).

Semi-Custom[861]

Use the following relationships along with NC, TOS and RF assumptions outlined above to estimate semi-custom costs.

Component	Type	Cost Function (per inch)	Inch Measurement
Standard V-Belt	A	$0.28/in + $0.96	Outside Length
Standard V-Belt	B	$0.29/in + $9.15	Outside Length
Standard Pulley	A, B, AX, BX	$11.85/in - $9.47	Outside Diameter
Notched Belt	AX	$0.36/in + $1.07	Outside Length
Notched Belt	BX	$0.49/in + $2.33	Outside Length
Synchronous Belt	1/2 inch	$0.58/in + $8.90	Pitch Length
Synchronous Belt	1 inch	$0.26/in + $5.67	Pitch Length
Synchronous Pulley	for use with 1/2 inch belt	$27.20/in - $21.19	Pitch Diameter
Synchronous Pulley	for use with 1 inch belt	$25.04/in - $27.23	Pitch Diameter

ESF = Energy Savings Factor, the ESF for notched v-belt Installation is assumed to be 2%

= the ESF for notched Synchronous Belt Installation is assumed to be 3.1%[866]

For example, a notched v-belt installation in an low rise office building RTU with a 5 HP NEMA premium efficiency motor using the default hours of operation, motor load and 89.5% motor efficiency;

ΔkWh = $kW_{connected}$* Hours * ESF

= ((HP * 0.746 kW/HP* Load Factor)/Motor Efficiency) * Hours * ESF

= ((5 HP * 0.746 kW/HP* 80%) / 89.5%) * 8116 * 2%

= 541.2 kWh Savings

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = kW_{connected} * ESF * CF$$

Where:

$kW_{Connected}$ = kW of equipment is calculated using motor efficiency.

= (HP *0 .746 kW/HP* Load Factor)/Motor Efficiency

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [867]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [868]

Variables as provided above

[866] Based on information found in Advanced Manufacturing Office, US DOE, "Replace V-Belts with Notched or Synchronous Drives", (US Department of Energy Motor Systems Tip Sheet #5, DOE/GO-102012-3740, November 2012). V-belt drives can have a peak efficiency of 95% and synchronous belts operate at 98%, therefore ESF is (1-95%/98%) = 3.1%.

[867] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[868]Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

For example, an office building RTU with a 5 HP NEMA premium efficiency motor using the default motor load and 89.5% motor efficiency;

ΔkW_{SSP} = $kW_{connected}$* ESF * CF

= ((HP * 0.746 kW/HP* Load Factor)/Motor Efficiency) * ESF * CF

= ((5 HP * 0.746 kW/HP* 80%) / 89.5%) * 2% * 0.913

= 0.0609 kW Savings

4.4.31 Small Business Furnace and Rooftop Unit Tune-Up

DESCRIPTION

This measure is for a fossil fuel Small Business furnace or Gas-Fired Rooftop Unit that provides space heating. The tune-up will improve furnace or gas-fired rooftop unit performance by inspecting, cleaning, and adjusting the furnace or rooftop unit and appurtenances for correct and efficient operation. Additional savings may be realized through a complete system tune-up.

This measure was developed to be applicable to the following program types: RF (small businesses).

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure an approved technician must complete the tune-up requirements listed below:[869]

- Measure combustion efficiency using an electronic flue gas analyzer
- Check and clean blower assembly and components per manufacturer's recommendations
- Where applicable lubricate motor and inspect and replace fan belt, if required
- Inspect for gas leaks
- Clean burner per manufacturer's recommendations and adjust as needed
- Check ignition system and safety systems and clean and adjust as needed
- Check and clean heat exchanger per manufacturer's recommendations
- Inspect exhaust/flue for proper attachment and operation
- Inspect control box, wiring and controls for proper connections and performance
- Check air filter and clean or replace per manufacturer's recommendations
- Inspect duct work connected to furnace for leaks or blockages
- Measure temperature rise and adjust flow as needed
- Check for correct line and load volts/amps
- Check thermostat operation is per manufacturer's recommendations (if adjustments made, refer to 'Small Commercial Programmable Thermostat Adjustment' measure for savings estimate)
- Perform Carbon Monoxide test and adjust heating system until results are within standard industry acceptable limits

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a furnace or a gas-fired rooftop unit assumed not to have had a tune-up in the past 3 years.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for the tune up is 3 years.[870]

DEEMED MEASURE COST

The incremental cost for this measure should be the actual invoiced cost of the tune-up.

[869] American Standard Heating & Air Conditioning, Maintenance for Indoor Units

[870] Assumed consistent with other tune-up measures. For more detail, see: 4.4.1 Air Conditioner Tune-Up (3 years is given for "Clean Condenser Coils – Commercial" and "Clean Evaporator Coils". DEER2014 EUL Table.) and 4.4.2 Space Heating Boiler Tune-Up (Act on Energy Commercial Technical Reference Manual No. 2010-4, 9.2.2 Gas Boiler Tune-up.)

DEEMED O&M COST ADJUSTMENTS

There are no expected O&M savings associated with this measure.

LOADSHAPE

Loadshape C04 - Commercial Electric Heating

COINCIDENCE FACTOR

Algorithms

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

ΔkWh = $\Delta Therms * F_e * 29.3$

Where:

ΔTherms = as calculated below

F_e = Furnace or rooftop fan energy consumption as a percentage of annual fuel consumption

= 7.7%[871]

29.3 = kWh per therm

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

ΔTherms =$(Capacity * EFLH * (((Eff_{before} + E_i)/ Effbefore) - 1)) / 100{,}000$

Where:

Capacity = Furnace gas input size (Btu/hr)

= Actual

EFLH = Equivalent Full Load Hours for heating in Existing Buildings are provided in section 4.4 HVAC End Use

Eff_{before} = Efficiency of the furnace before the tune-up

= Actual

Note: Contractors should select a mid-level firing rate that appropriately represents the average building operating condition over the course of the heating season and take readings at a consistent firing rate for pre and post tune-up.

E_i = Efficiency Improvement of the furnace tune-up measure

= Actual

100,000 = Converts Btu to therms

[871] F_e is estimated using TRM models for the three most popular building types for programmable thermostats: low-rise office (10.2%), sit-down restaurant (8.6%), and retail – strip mall (4.4%). 7.7% reflects the average Fe of the three building types. See "Fan Energy Factor Example Calculation 2021-06-23.xlsx" for reference.

For example, a 200 kBtu furnace in a Rockford low rise office records an efficiency prior to tune up of 82% AFUE and a 1.8% improvement in efficiency are tune up:

Δtherms = (200,000 * 1428 * (((0.82 + 0.018)/ 0.82) – 1)) /100,000

= 62.3 therms

4.4.32 Combined Heat and Power

DESCRIPTION

During 2021 and 2022, a TAC CHP Working Group held multiple discussions with a view to updating this measure. While some progress was made, including moving towards a more custom approach, a difference in policy interpretation relating to the appropriate calculation of gas savings, and the appropriate data for determining emission rates over the lifetime of the measure, has prevented reaching consensus. Discussions will continue in 2023 and if required a non-consensus exhibit will be completed and filed in order that the Commission can provide a ruling on the appropriate methodology. Until then, the existing version of this measure is maintained.

The Combined Heat and Power (CHP) measure can provide energy savings within the State of Illinois through the development and operation of CHP projects. This measure is applicable for Conventional or Topping Cycle CHP systems, as well as Waste Heat-to-Power (WHP) or Bottoming Cycle CHP systems. The measure will reduce the total Btu's of energy required to meet the end use needs of the facility.

It is recognized that CHP system design and configuration may be complex, and as such the calculation of energy savings may not be reducible to the equations within this measure. In such cases a more comprehensive engineering and financial analysis may be developed that more accurately incorporates the attributes of complex CHP configurations such as variable-capacity systems, and partial combined-cycle CHP systems. Where noted, the use of values that are determined through an external engineering analysis may be substituted by agreement between the participant, the program administrator and independent evaluator. This substitution of values does not eliminate ex post evaluation risk (retroactive adjustments to savings claims) that exists when using custom inputs.

Due to the long planning horizon for CHP projects, CHP projects will use the project permit date to determine the version of the IL-TRM the implementation teams will follow. The purpose of this is to confirm the savings calculation methodologies for projects as early as possible due to the long planning horizon for the measure.

This measure was developed to be applicable to the following program types: Retrofit (RF), New Construction (NC). If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Conventional or Topping Cycle CHP is defined as an integrated system that is located at or near the building or facility (on-site, on the customer side of the meter) that utilizes a prime mover (reciprocating engine, gas turbine, micro-turbine, fuel cell, boiler/steam turbine combination) for the purpose of generating electricity and useful thermal energy (such as steam, hot water, or chilled water) where the primary function of the facility where the CHP is located is not to generate electricity for use on the grid. An eligible system must demonstrate a minimum total system efficiency of 60% (HHV),[872] with at least 20% of the system's total useful energy output in the form of useful thermal energy on an annual basis.

Measuring and Calculating Conventional CHP Total System Efficiency:

CHP efficiency is calculated using the following equation:

$$CHP\ _{Efficiency}(HHV) = \frac{\left[CHP_{thermal}\ \left(\frac{kBtu}{yr}\right) + E_{CHP}\ \left(\frac{kWh}{yr}\right) * 3.412\ \left(\frac{kBtu}{kWh}\right)\right]}{F_{totalCHP}\left(\frac{kBtu}{yr}\right)}$$

Where:

[872] Higher Heating Value (HHV): refers to the heating value of the fuel and is defined as the total thermal energy available, including the heat of condensation of water vapors, resulting from complete combustion of the fuel versus the Lower Heating Value (LHV), which assumes the heat of condensation is not available.

$CHP_{thermal}$ = Useful annual thermal energy output from the CHP system, defined as the annual thermal energy output of the CHP system that is actually recovered and utilized in the facility/process.

E_{CHP} = Useful annual electricity output produced by the CHP system, defined as the annual electric energy output of the CHP system that is actually utilized to replace purchased electricity required to meet the requirements of the facility/process.

$F_{totalCHP}$ = Total annual fuel consumed by the CHP system

For further definition of the terms, please see "Calculation of Energy Savings" Section below.

Waste Heat-to-Power or Bottoming Cycle CHP is defined as an integrated system that is located at or near the building or facility (on-site, on the customer side of the meter) that does one of the following:

- Utilizes exhaust heat from an industrial/commercial process to generate electricity (except for exhaust heat from a facility whose primary purpose is the generation of electricity for use on the grid); or
- Utilizes the pressure drop in an industrial/commercial facility to generate electricity through a backpressure steam turbine where the facility normally uses a pressure reducing valve (PRV) to reduce the pressure in their facility; or
- Utilizes the pressure reduction in natural gas pipelines (located at natural gas compressor stations) before the gas is distributed through the pipeline to generate electricity, provided that the conversion of energy to electricity is achieved without using additional fossil fuels.

Since these types of systems utilize waste heat as their fuel, they do not have to meet any specific total system efficiency level (assuming they use no additional fossil fuel in their operation) If additional fuel is used onsite, it should be accounted for using the following methodology:

- Treat the portion of Waste-Heat-to-Power that does not require any additional fuel using the Waste-Heat-to-Power methodology outlined in this document.
- Treat the portion of Waste-Heat-to-Power that requires additional fuel (if natural gas) using the Conventional CHP methodology outlined in this document. If the additional fuel is not natural gas, custom carbon equivalency calculations would be needed – refer to section "Calculation of Energy Savings" for more details.
- Add the energy savings together.

These systems may export power to the grid.

DEFINITION OF BASELINE EQUIPMENT

Electric Baseline: The baseline facility would be a facility that purchases its electric power from the grid.

Heating Baseline (for CHP applications that displace onsite heat): The baseline equipment would be the boiler/furnace operating onsite, or a boiler/furnace meeting the baseline equipment defined in the High Efficiency Boiler (Section 4.4.10)/Furnace (Section 4.4.11) measures of this TRM.

Cooling Baseline (for CHP applications that displace onsite cooling demands): The baseline equipment would be the chiller (or chillers) operating onsite, or a chiller (or chillers) meeting the definition of baseline equipment defined in the Electric Chiller (Section 4.4.6) measure of this TRM.

Facilities that use biogas or waste gas: Facilities that use (but are not purchasing) biogas or waste gas that is not otherwise used, whether they are using biogas or waste gas only or a combination of biogas or waste gas and natural gas to meet their energy demands are also eligible for this measure. If additional fuel is purchased to power the CHP system, then the additional natural gas should be taken into account using the following methodology:

- Treat the portion of CHP system that does not require any additional fuel, or that requires additional fuel that would otherwise be wasted (e.g., flared), using the Waste-Heat-to-Power methodology outlined in this document.

- Treat the portion of CHP that requires additional fuel (if natural gas) using the Conventional CHP methodology outlined in this document. If the additional fuel is not natural gas, custom carbon equivalency calculations would be needed – refer to section "Calculation of Energy Savings" for more details.
- Add the energy savings together.

Consumption of any biogas or waste gas that would not otherwise being wasted (e.g., flared) will be accounted for in the overall net BTU savings calculations the same as for purchased natural gas.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

Measure life is a custom assumption, dependent on the technology selected and the system installation.

DEEMED MEASURE COST

Custom installation and equipment cost will be used. These costs should include the cost of the equipment and the cost of installing the equipment. Equipment costs include, but are not limited to: prime mover, heat recovery system(s), exhaust gas treatment system(s), controls, and any interconnection/electrical connection costs.

The installations costs include labor and material costs such as, but not limited to: labor costs, materials such as ductwork, piping, and wiring, project and construction management, engineering costs, commissioning costs, and other fees.

Measure costs will also include the present value of expected maintenance costs over the life of the CHP system.

LOADSHAPE

Use Custom Loadshape. The loadshape should be obtained from the actual CHP operation strategy, based on the On-Peak and Off-Peak Energy definitions specified in Table 3.3 of "Section 3.5 Electrical Loadshapes" of the TRM.

COINCIDENCE FACTOR

Custom coincidence factor will be used. Actual value based on the CHP operation strategy will be used.

Algorithm

CALCULATION OF ENERGY SAVINGS

i) Conventional or Topping Cycle CHP Systems:

Step 1: (Calculating Total Annual Source Fuel Savings in Btus)

The first step is to calculate the total annual source fuel savings associated with the CHP installation, in order to ensure the CHP project produces positive total annual source fuel savings (i.e., reduction in source Btus):

$S_{FuelCHP}$ = Annual fuel savings (Btu) associated with the use of a Conventional CHP system to generate the useful electricity output (kWh, converted to Btu) and useful thermal energy output (Btu) versus the use of the equivalent electricity generated and delivered by the local grid and the equivalent thermal energy provided by the onsite boiler/furnace.

$= (F_{grid} + F_{thermalCHP}) - F_{total\ CHP}$

Where:

F_{grid} = Annual fuel in Btu that would have been used to generate the useful electricity output of the CHP system if that useful electricity output was provided by the local utility grid.

$= E_{CHP} * H_{grid}$

Where:

E_{CHP} = Useful annual electricity output produced by the CHP system, defined as the annual electric energy output of the CHP system that is actually utilized to replace purchased electricity required to meet the requirements of the facility/process. [873]

= ($CHP_{capacity}$ * Hours) - $E_{Parasitic}$

$CHP_{capacity}$ = CHP nameplate capacity

= Custom input

Hours = Annual operating hours of the system

= Custom input

$E_{parasitic}$ = The electricity required to operate the CHP system that would otherwise not be required by the facility/process

= Custom input

H_{grid} = Heat rate of the grid in Btu/kWh, based on the average fossil heat rate for the EPA eGRID subregion, adjusted to take into account T&D losses.

For systems operating less than 6,500 hrs per year:

Use the Non-baseload heat rate provided by EPA eGRID for RFC West region for ComEd territory (including independent providers connected to RFC West), and SERC Midwest region for Ameren territory (including independent providers connected to SERC Midwest).[874] Also include any line losses.

For systems operating more than 6,500 hrs per year:

Use the All Fossil Average heat rate provided by EPA eGRID for RFC West region for ComEd territory (including independent providers connected to RFC West), and SERC Midwest region for Ameren territory (including independent providers connected to SERC Midwest). Also include any line losses.

$F_{thermalCHP}$ = Annual fuel in Btu that would have been used on-site by a boiler/furnace to provide the useful thermal energy output of the CHP system.[875]

= $CHP_{thermal}$ / $Boiler_{eff}$ (or $CHP_{thermal}$ / $Furnace_{eff}$)

$CHP_{thermal}$ = Useful annual thermal energy output from the CHP system, defined as the annual thermal energy output of the CHP system that is actually recovered and utilized in the facility/process.

= Custom input

$Boiler_{eff}$ /$Furnace_{eff}$= Efficiency of the on-site Boiler/Furnace that is displaced by the CHP system or if unknown, the baseline equipment value stated in the High Efficiency Boiler (Section 4.4.10) measure or High Efficiency Furnace (Section 4.4.11) measure in this TRM.

= Custom input

[873] For complex systems this value may be obtained from a CHP System design/financial analysis study.

[874] These values are subject to regular updates so should be reviewed regularly to ensure the current assumptions are correct. Refer to the latest EPA eGRID data. Current values, based on eGrid 2018 are:
Non-Baseload RFC West: 10,024 Btu/kWh * (1 + Line Losses)
Non-Baseload SERC Midwest: 9,871 Btu/kWh * (1 + Line Losses)
All Fossil Average RFC West: 9,575 Btu/kWh * (1 + Line Losses)
All Fossil Average SERC Midwest: 10,369 Btu/kWh * (1 + Line Losses)

[875] For complex systems this value may be obtained from a CHP System design/financial analysis study.

$F_{total\ CHP}$ = Total fuel in Btus consumed by the CHP system

= Custom input

Step 2: (Savings Allocation to Program Administrators for Purposes of Assessing Compliance with Energy Savings Goals (Not for Use in Load Reduction Forecasting))

Savings claims are a function of the electric output of the CHP system (E_{CHP}), the used thermal output of the CHP system ($F_{thermalCHP}$), and the CHP system efficiency (CHP_{Eff}(HHV)). The percentages of electric output and used thermal output that can be claimed also differ slightly depending on whether the project was included in both electric[876] and gas[877] Energy Efficiency Portfolio Standard (EEPS)[878] efficiency programs, only an electric EEPS program or only a gas EEPS program. The tables below provide the specific percentages of electric and/or thermal output that can be claimed under each of those three scenarios. These percentages apply only to cases in which natural gas is the fuel used by the CHP system. Saving estimates for systems using other fuels should be calculated on a custom basis. If the waste heat recovered from the CHP system is offsetting electric equipment, such as an absorption chiller offsetting an electric chiller, then the net change in electricity consumption associated with the electric equipment should be added to the allocated electric savings.

1) For systems participating in both electric EEPS and gas EEPS programs:

CHP Annual System Efficiency (HHV)	Allocated Electric Savings	Allocated Gas Savings
60%	65% of E_{CHP} (kWh)	No gas savings
>60% to 65%	65% of E_{CHP} (kWh) + one percentage point increase for every one percentage point increase in CHP system efficiency (max 70% of E_{CHP} in kWh)	No gas Savings
>65%	70% of E_{chp} (kWh)	2.5% of $F_{thermal}$ (Boiler Natural Gas offset by CHP thermal) for every one percentage point increase in CHP system efficiency above 65%.

Example: System with measured annual system efficiency (HHV) of 70%: Electric savings (kWh) = 70% of E_{CHP} measured over 12 months, and Gas savings (therms) = 12.5% of $F_{thermal}$ measured over 12 months (70% - 65% = 5 X 2.5% = 12.5%).

2) For systems participating in only an electric EEPS program:

CHP Annual System Efficiency (HHV)	Allocated Electric Savings	Allocated Gas Savings
60%	65% of E_{CHP} (useful electric output of CHP system in kWh)	No gas Savings
Greater than 60%	65% + one percentage point increase for every one percentage point increase in CHP system efficiency (no max)	No gas Savings

Example: System with measured annual fuel use efficiency of 75%: Electric savings (kWh) = 65% + 15% = 80% of E_{CHP} measured over 12 months (15% = 1% for every 1% increase in system efficiency). No gas savings (therms).

3) For systems participating in only a gas EEPS program:

CHP Annual System Efficiency (HHV)	Allocated Electric Savings	Allocated Gas Savings
60% or greater	No electric savings	2.5% of Fthermal (Boiler Natural Gas offset by CHP thermal) for every one percentage point increase in CHP system efficiency above 60%.

Example: System with measured annual system efficiency (HHV) of 70%: No Electric savings (kWh). Gas savings (therms) = 25% of $F_{thermal}$ measured over 12 months (70% - 60% = 10 X 2.5% = 25%).

Conventional or topping cycle CHP systems virtually always require an increase in the use of fuel on-site in order to produce electricity. Different jurisdictions and experts across the country have employed and/or put forward a variety of approaches to address how increased on-site fuel consumption should be reflected in the attribution of electric savings to CHP systems.[879] The approach reflected in the tables above is generally consistent – for CHP systems consuming natural gas – with approaches recently put forward by the Southwest Energy Efficiency Project (SWEEP) and Institute for Industrial Productivity (IIP) that determine reduced electric savings based on the equivalent amount of carbon dioxide generated from the increased fuel used.[880]

There are a variety of ways one could treat the potential for gas utilities to claim savings from CHP projects in their EEPS portfolios. For projects in which a natural gas EEPS program is involved, the tables above treat savings from CHP installations in two steps: (1) a fuel-switch from electricity to natural gas (i.e., using more natural gas to eliminate the need to generate as much electricity on the grid); and (2) possible increases in CHP efficiency above a "benchmark" level. When both electric EEPS and natural gas EEPS programs are involved in a project, the program administrator claims all the electricity savings associated with a fuel-switch up to a "benchmark" 65% efficient CHP system. All the savings associated with increasing CHP efficiencies above that benchmark level are allocated to natural gas (e.g., if the CHP efficiency is 75%, the natural gas savings associated with an increase in CHP efficiency from 65% to 75% are allocated to natural gas). That is consistent with the notion that CHP efficiency typically increases primarily by increasing the use of the thermal output of the system (increasing the displacement of baseline gas use). For projects that involve only a natural gas EEPS program, the "benchmark" above which the gas utility can claim savings is lowered to 60%.

ii) **Waste-Heat-to-Power CHP Systems :**

ELECTRIC ENERGY SAVINGS:

$$\Delta kWh = E_{CHP}$$

Where:

E_{CHP} = Useful annual electricity output produced by the CHP system, defined as the annual electric energy output of the CHP system that is actually utilized to replace purchased electricity required to meet the requirements of the facility/process.

= Custom input

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = CF * CHP_{capacity}$$

Where:

CF = Summer Coincidence factor. This factor should also consider any displaced chiller capacity.[881]

= Custom input

$CHP_{Capacity}$ = CHP nameplate capacity

= Custom input

FOSSIL FUEL ENERGY SAVINGS:

$$\Delta Therms = F_{thermalCHP} \div 100{,}000$$

Where:

$F_{thermalCHP}$ = Net savings in annual purchased fuel in Btu, if any, that would have been used on-site by a boiler/furnace to provide some or all of the useful thermal energy output of the CHP system.[882]

100,000 = Conversion factor for Btu to therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

Custom estimates of maintenance costs that will be incurred for the life of the measure will be used**.** Maintenance costs vary with type and size of the prime mover. These costs include, but are not limited to:

- Maintenance labor
- Engine parts and materials such as oil filters, air filters, spark plugs, gaskets, valves, piston rings, electronic components, etc. and consumables such as oil
- Minor and major overhauls

For screening purposes, the US EPA has published resource guides that provide average maintenance costs based on CHP technology and system size.[883]

COST-EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING

For the purposes of forecasting load reductions due to CHP projects, changes in site energy use at the customer's meter – reduced consumption of utility provided electricity – adjusted for utility line losses (at-the-busbar savings), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

For the purposes of screening a CHP measure application for cost-effectiveness, changes in site energy use – reduced consumption of utility provided electricity and the net change in consumption of fuel – should be used. In general, the benefit and cost components used in evaluating the cost-effectiveness of a CHP project would include at least the following terms:

[881] If some or all of the existing electric chiller peak demand is no longer needed due to new waste heat powered chillers (e.g., absorption), the coincidence factor should be adjusted appropriately.

[882] In most cases, it is expected that waste-heat-to-power systems will not provide any new net useful thermal energy output, since the CHP system will be driven by thermal energy that was otherwise being wasted. If additional natural gas or other purchased energy is used onsite, it should be properly accounted for.

[883] "EPA Combined Heat and Power Partnership Resources" Oct 07, 2014, in the document "Catalog of CHP Technologies", US EPA, September 2017, pages 2-16,, 3-14, 4-14, 5-14, and 6-16.

MEASURE CODE: CI-HVC-CHAP-V07-230101

REVIEW DEADLINE: 1/1/2025

4.4.33 Commercial & Industrial Air Curtain

DESCRIPTION

This measure applies to buildings with exterior entryways that utilize overhead doors. All other air curtain applications, such as through sliding door entryways or conventional foot-traffic entryways, require custom analysis as air curtain designs must often accommodate other factors that may change their effectiveness.

The use of overhead doors within exterior entryways during the heating season leads to the exfiltration of warm air from the upper portion of the door opening and the infiltration of colder air from the lower portion of the door opening. This results in increase heating energy use to compensate for heat losses every time a door is opened. By reducing heat losses, air curtains can also enhance the physical comfort of employees or customers near the entryway as there will be reduced temperature fluctuations when the door is opened and closed. In addition, in some cases excess heating capacity may be installed in buildings to meet this larger heating load. The addition of air curtains to exterior entryways that currently utilize overhead doors will result in energy savings and enhanced personal comfort, and also possibly in reduced equipment sizing and corresponding costs.

The primary markets for this measure are commercial and industrial facilities with overhead doors in exterior entryways, including but not limited to the following building types: retail, manufacturing, and warehouse (non-refrigerated).

Limitations

- For use in conditioned spaces with an overhead door in an exterior entryway.
- This measure should only be applied to spaces in which the overhead door separates a conditioned space and an unconditioned space.
- Installation must follow manufacturer recommendations to attain proper air velocity, discharge angle down to the floor level, and unit position.
- Certain heating systems may not be a good fit for air curtains, such as locations with undersized heating capacity. In these cases, the installation of an air curtain may not effectively reduce heating system cycling given the inappropriately sized heating capacity.
- Buildings with slightly positive to slightly negative (~5 Pa to -10 Pa). For all other scenarios, custom analysis is recommended.
- Measure assumes that wind speeds at near ground level are less than or equal to 12 mph for 90% of the heating or cooling season. For areas with more extreme weather, custom analysis is necessary.
- Note: for cost effectiveness, it is recommended that minimum door open times should be approximately 15 hours per week.[884]

This measure was developed to be applicable to the following program types: NC, RF. If applied to other program types, the measure savings should be verified.

The following methodology is highly complex and requires significant data collection. It is hoped that simplifying steps can be made in future iterations based on continued metering and evaluation of installations. Also the data collected through implementing the measure in the way currently drafted will aid in simplifying efforts at a future date.

DEFINITION OF EFFICIENT EQUIPMENT

Overhead air curtains designed for commercial and industrial applications that have been tested and certified in accordance with ANSI/AMCA 220 and installed following manufacturer guidelines. Measure is for standard models without added heating.

[884] Spentzas, Steve, et. al, "1009: Commercial and Industrial Air Curtains – Public Project Report," Nicor Gas Emerging Technology Program (Oct 2014): 9.

DEFINITION OF BASELINE EQUIPMENT

No air curtain or other currently installed means to effectively reduce heat loss and air mixing during door openings, such as a vestibule or strip curtain.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years.[885]

DEEMED MEASURE COST

The incremental capital cost for overhead air curtains for exterior entryways are as follows, with an added average installation cost approximately equal to the capital cost.[886]

Door Size	Capital Cost
3.5'w x 7'h	$1,500
6'w x 7'h	$2,500
8'w x 8'h	$3,600
10'w x 10'h	$4,500
10'w x 12'h	$5,400
12'w x 14'h	$8,000
16'w x 16'h	$13,300

LOADSHAPE

Heating Season: If electric heating, use Commercial Electric Heating Loadshape: C04. Otherwise, N/A

Cooling Season: Commercial Cooling Loadshape C03. Or, if applicable, use Commercial Electric Heating and Cooling Loadshape C05.

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%[887]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [888]

Algorithm

CALCULATION OF ENERGY SAVINGS

The following formulas provide a methodology for estimating cooling load (kWh) and heating load (therm) savings associated with the installation of air curtains on exterior entryways such as a single door or loading bay. This algorithm is based on the assumption that therm savings are directly related to the difference in cooling or heating losses due to infiltration or exfiltration through an entryway before and after the installation of an AMCA certified

[885] Navigant Consulting Inc, Measures and Assumptions for Demand Side Management (DSM) Planning: Appendix C: Substantiation Sheets, "Air Curtains – Single Door," Ontario Energy Board, (April 2009): C-137.
2014 Database for Energy-Efficient Resources, EUL/RUL (Effective/Remaining Useful Life) Values, February 4, 2014.
[886] Based on manufacturer interviews and air curtain specification sheets. Smaller doors are estimated based on interpolation of larger door costs.
[887] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[888]Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

air curtain. Energy savings are assumed to be the result of a reduction of natural infiltration effects due to wind and thermal forces and follow the calculation methodology outlined by the ASHRAE Handbook.[889] The calculation assumes that the air curtain is appropriately sized and commissioned to be effective in mitigating infiltration of winds of up to 12 mph for at a least 90% of the year (based on manufacturer literature and TMY3 wind speed ranges at near ground level for Illinois).[890] Additionally, this measure assumes the HVAC systems are appropriately balanced such that the maximum pressure differential between indoor air and outdoor air is within the range of 5 Pa < ΔP < -10 Pa.[891] Custom analysis is necessary if building pressurization exceeds this range. However, while effectiveness decreases, some studies suggest that air curtains outperform vestibules and single door construction for negatively pressurized buildings with a ΔP of above -30 Pa.[892]

This algorithm allows either actual inputs or provides estimates if actual data is not available. All weather dependent values are derived from TMY3 data for the closest weather station to those locations defined elsewhere in the Illinois TRM (which are based on 30 year climate normals). If TMY3 weather station data was not available for the data used in the Illinois TRM, the next closest weather station was used. It is assumed that weather variations are negligible between the weather stations located within the same region. This approach was followed as the air curtain algorithm has a number of weather dependent variables, which are all calculated in relation to the heating season or cooling season as defined by the balance point temperature deemed appropriate for the facility. All weather dependent data is based on TMY3 data and is listed in tables by both climate zone and balance point temperature, which is then normalized to the Illinois TRM climate zoned HDD/CDD definitions unless otherwise noted.

ELECTRIC ENERGY SAVINGS

$$\Delta kWh_{cooling} = [(Q_{tbc} - Q_{tac}) / \eta Cool - (HP * 0.7457)] * t_{open} * CD$$

$$\Delta kWh_{HPheating} = [(Q_{tbc} - Q_{tac}) / \eta Heat_Electric - (HP * 0.7457)] * t_{open} * HD$$

$$\Delta kWh_{Gasheating} = -(HP * 0.7457) * t_{open} * HD$$

Where:

Q_{tbc} = rate of total heat transfer through the open entryway, before air curtain (kBtu/hr)

Q_{tac} = rate of total heat transfer through the open entryway, after air curtain (kBtu/hr)

(see calculation in 'Heat Transfer Through Open Entryway with/without Air Curtain' sections below)

ηCool = energy efficiency ratio of the cooling equipment (kBtu/kWh) * distribution efficiency.

= Actual. If unknown, use the table C403.2.3(2) in IECC 2012 (or IECC 2021 if through new construction) and assume 95% distribution efficiency for central cooling with ducts. If unknown assume:[893]

Space Cooling Source	Deemed Cooling EER2	Deemed Cooling SEER2
No Cooling	N/A	N/A
Unknown Cooling Source	10.2	11.1

[889] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): Ch 16.1 - 16.37.

[890] National Solar Radiation Data Base – 1991 – 2005 Update: Typical Meteorological Year 3, NREL.

[892] Wang, Liangzhu, "Investigation of the Impact of Building Entrance Air Curtain on Whole Building Energy Use," Air Movement and Control International, Inc. (2013). 4.

[893] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER and EER values converted to SEER2/EER2 by multiplying by 0.95, and multiplied by 0.95 distribution efficiency.

HP = Input power for air curtain (hp)

= Actual value. If actual value not available, use the following estimates based on manufacturer specs

Door Size	Fan HP
3.5'w x 7'h	0.5
6'w x 7'h	0.75
8'w x 8'h	1
10'w x 10'h	1.5
10'w x 12'h	4
12'w x 14'h	6
16'w x 16'h	12

0.7457 = unit conversion factor, brake horsepower to electric power (kW/HP)

t_{open} = average hours per day the door is open (hr/day)

= Actual or user defined estimated value.

CD = cooling days per year, total days in year above balance point temperature (day)

= use table below to select the best value for location:[894]

.	CD (Balance Point Temperature)				
Climate Zone -Weather Station/City	45 °F	50 °F	55 °F	60 °F	65 °F
1 - Rockford AP / Rockford	194	168	148	124	97
2 - Chicago O'Hare AP / Chicago	194	173	153	127	95
3 - Springfield #2 / Springfield	214	194	174	148	114
4 - Belleville SIU RSCH / Belleville	258	229	208	174	138
5 - Carbondale Southern IL AP / Marion	222	201	181	158	130

ηHeat_Electric = Efficiency of heating system, including distribution efficiency.

= Actual. If unknown, use the table C403.2.3(2) in IECC 2012 (or IECC 2021 if through new construction) and assuming 0.95 distribution efficiency.

Alternatively, as deemed from table below:

System Type	HSPF2 Estimate	ηHeat (HSPF2 * 0.95)
Heat Pump	7.37[895]	7.0

[894] National Solar Radiation Data Base – 1991 – 2005 Update: Typical Meteorological Year 3, NREL.
Note that cooling days (CD) are calculated by first determining its value from the TMY3 data associated with the appropriate weather station as defined by and used elsewhere in the Illinois TRM. Using the TMY3 outdoor air dry bulb hourly data, the annual hours are totaled for every hour that the outdoor air dry bulb temperature is above a designated zero heat loss balance point temperature or base temperature for cooling. For commercial and industrial (C&I) buildings, a base temperature for heating of 55 °F is designated in the Illinois TRM, but building specific base temperatures are recommended for large C&I projects. Additionally, the TRM uses a 30-year normal data for degree-days while the CD calculation was based on TMY3 data; in order to account for this, calculations of CD were also normalized by the ratio of CDD to align the calculated values more closely with the TRM.

[895] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note HSPF value converted to HSPF2 by multiplying by 0.85.

System Type	HSPF2 Estimate	ηHeat (HSPF2 * 0.95)
Resistance	N/A	1

HD = heating days per year, total days in year above balance point temperature (day)

= use table below to select an appropriate value:[896]

	HD				
Climate Zone Weather Station/City	45 °F	50 °F	55 °F	60 °F	65 °F
1 - Rockford AP / Rockford	142	160	183	204	228
2 - Chicago O'Hare AP / Chicago	150	166	192	219	253
3 - Springfield #2 / Springfield	125	142	167	194	230
4 - Belleville SIU RSCH / Belleville	101	115	134	156	180
5 - Carbondale Southern IL AP / Marion	103	123	148	174	205

Heat Transfer Through Open Entryway without Air Curtain (Cooling Season)

Q_{tbc} $= 4.5 * CFM_{tot} * (h_{oc} - h_{ic}) / (1{,}000\ Btu/kBtu)$

Where:

4.5 = unit conversion factor with density of air: 60 min/hr * 0.075 lbm/ft3 (lb*min/(ft*hr))

CFM_{tot} = Total air flow through entryway (cfm), see calculation below

h_{oc} = average enthalpy of outside air during the cooling season (Btu/lb)

= use the below table to determine the approximate outdoor air enthalpy associated with an indoor temperature setpoint and climate zone.[897]

	h_{oc}		
Climate Zone -Weather Station/City	67 °F	72 °F	77 °F
1 - Rockford AP / Rockford	31.6	33.0	35.3
2 - Chicago O'Hare AP / Chicago	32.0	33.6	35.4
3 - Springfield #2 / Springfield	32.9	34.6	36.6
4 - Belleville SIU RSCH / Belleville	33.5	35.0	36.4
5 - Carbondale Southern IL AP / Marion	34.6	36.2	37.7

h_{ic} = average enthalpy of indoor air, cooling season (Btu/lb)

= use the below table to determine the approximate indoor air enthalpy associated with an indoor temperature setpoint in indoor relative humidity.

	h_{ic}		
Relative Humidity (%)	67 °F	72 °F	77 °F
60	25.5	28.5	31.8
50	23.9	26.6	29.5
40	22.3	24.7	27.3

[896] Note that Heating Days (HD) are calculated following the same approach outlined in the Cooling Days section.

[897] Average enthalpies were estimated following ASHRAE guidelines for perfect gas relationships for dry air associated with hourly TMY3 data. Enthalpies were then averaged for all values associated with a dry-bulb outdoor air temperature that exceeded the indoor air temperature setpoint. Other enthalpy values may be interpolated for indoor air temperature setpoints not represented in the table. Note that while outdoor air enthalpies increase with higher temperature setpoints, the change in enthalpy from indoor to outdoor will decrease.

= an estimate 26.6 Btu/lb associated with the 72 °F and 50% indoor relative humidity case can be used as an approximation if no other data is available. For other indoor temperature setpoints and RH, enthalpies may be interpolated or a psychrometric chart may be referenced.

The total airflow through the entryway, CFM_{tot}, includes both infiltration due to wind as well as thermal forces, as follows:

$$CFM_{tot} = \sqrt{[\ (CFM_w)^2 + (CFM_t^2)\ ]}$$

Where:

CFM_w = Infiltration due to the wind (cfm)

CFM_t = Infiltration due to thermal forces (cfm)

The infiltration due to the wind is calculated as follows:

$$CFM_w = (v_{wc} * C_{wc}) * C_v * A_d * (88\ fpm/mph)$$

Where:

v_{wc} = average wind speed during the cooling season based on entryway orientation (mph)

= use the below table to for the wind speed effects based on climate zone and entryway orientation:[898]

	Entryway Orientation			
Climate Zone -Weather Station /City	**N**	**E**	**S**	**W**
1 - Rockford AP / Rockford	4.2	4.1	4.7	4.8
2 - Chicago O'Hare AP / Chicago	4.7	4.5	5.4	4.6
3 - Springfield #2 / Springfield	4.1	3.7	6.0	5.0
4 - Belleville SIU RSCH / Belleville	3.3	2.7	3.8	4.2
5 - Carbondale Southern IL AP / Marion	3.1	2.9	4.4	3.8

C_{wc} = wind speed correction factor due to wind direction in cooling season (%)

= because wind direction is not constant, a wind speed correction factor is used to adjust for the amount of time during the cooling season prevailing winds can be expected to impact the entryway. Use the following table to determine the correct wind speed correction factor for cooling applications.

	Entryway Orientation			
Climate Zone -Weather Station/City	**N**	**E**	**S**	**W**
1 - Rockford AP / Rockford	0.18	0.13	0.30	0.31
2 - Chicago O'Hare AP / Chicago	0.18	0.17	0.36	0.26
3 - Springfield #2 / Springfield	0.17	0.12	0.46	0.21
4 - Belleville SIU RSCH / Belleville	0.21	0.15	0.35	0.16
5 - Carbondale Southern IL AP / Marion	0.18	0.15	0.37	0.11

Note that correction factors do not add up to 1 (100%). This is attributed to periods of calm winds.

C_v = effectiveness of openings,

[898] Average wind speeds are calculated based on the TMY3 wind speed data. Because this data is collected at an altitude of 33 ft, wind speed is approximated for a 5 ft level based on ASHRAE Handbook guidelines using the urban/suburban parameters for adjusting wind speed based on altitude (Layer thickness (ft) δ = 1200, Exponent a = 0.22).
ASHRAE, "Airflow Around Buildings," in 2013 ASHRAE Handbook – Fundamentals (2013): p 24.3.

= 0.3, assumes diagonal wind[899]

A_d = area of the doorway (ft^2)

= user defined

The infiltration due to thermal forces is calculated as follows:

$CFM_t = A_d * C_{dc} * (60\ sec/min) * \sqrt{[2 * g * H/2 * (T_{oc} - T_{ic}) / (459.7 + T_{oc})]}$

Where:

C_{dc} = the discharge coefficient during the cooling season[900]

= $0.4 + 0.0025 * |T_{ic} - T_{oc}|$

= 0.42, Illinois average at indoor air temp of 72°F

Note, values for C_{dc} show little variation due to balance point temperature, indoor air temperature, and climate zone. As such, if estimating results, the Illinois average value may be used as a simplification.

g = acceleration due to gravity

= 32.2 ft/sec^2

H = the height of the entryway (ft)

= user input

T_{ic} = Average indoor air temperature during cooling season

= User input, can assume indoor cooling temperature set-point

T_{oc} = Average outdoor temp during cooling season (°F)

= the average outdoor temperature is dependent on the CD period and zone. As such, the following table may be used for average outdoor temperature during the cooling period:[901]

	T_{oc}				
Climate Zone Weather Station/City	**62 °F**	**67 °F**	**72 °F**	**77 °F**	**82 °F**
1 - Rockford AP / Rockford	72.9	76.0	79.2	82.5	85.5
2 - Chicago O'Hare AP / Chicago	72.9	76.0	79.4	82.8	85.5
3 - Springfield #2 / Springfield	73.7	76.7	79.9	83.4	86.4
4 - Belleville SIU RSCH / Belleville	74.9	77.7	81.0	84.3	86.9
5 - Carbondale Southern IL AP / Marion	75.1	77.7	80.9	84.7	87.4

459.7 = conversion factor from °F to °R

= calculation requires absolute temperature for values not calculated as a difference of temperatures.

Heat Transfer Through Open Entryway with Air Curtain (Cooling Season)

$Q_{tac} = Q_{tbc} * (1 - E)$

Where:

E = the effectiveness of the air curtain (%)

[899] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): p 16.13

[900] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): p 16.13.

[901] Based on binned data from TMY3 & adjusted bracketed thermostat setpoint temperatures. Interpolate other values as needed.

= 0.60[902]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (\Delta kWh_{cooling} / (CD * 24)) * CF$$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%[903]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [904]

FOSSIL FUEL SAVINGS

Natural gas savings, Δtherms, associated with reduced infiltration through an entryway during the heating season are calculated by determining the difference between heat loss through the entryway before and after the installation of the air curtain.

$$\Delta\text{therms} = (Q_{bc} - Q_{ac}) * t_{open} * HD / \eta Heat_Fossil$$

Where:

Q_{bc} = rate of sensible heat transfer through the open entryway, before air curtain (therm/hr)

Q_{ac} = rate of sensible heat transfer through the open entryway, after air curtain (therm/hr)

t_{open} = average hours per day the door is open (hr/day)

= Actual or estimated user input value

HD = heating days per year, total days in year above balance point temperature (day)

= use table below to select an appropriate value:[905]

	HD				
Climate Zone - Weather Station/City	**45 °F**	**50 °F**	**55 °F**	**60 °F**	**65 °F**
1 - Rockford AP / Rockford	142	160	183	204	228
2 - Chicago O'Hare AP / Chicago	150	166	192	219	253
3 - Springfield #2 / Springfield	125	142	167	194	230
4 - Belleville SIU RSCH / Belleville	101	115	134	156	180
5 - Carbondale Southern IL AP / Marion	103	123	148	174	205

ηHeat_Fossil = efficiency of heating equipment * Distribution Efficiency

[902] Assumed conservative estimate based on referenced study results and ASHRAE 2004 effectiveness range of 60-80% for air curtains. Jaramillo, Julian, et. Al. "Application of Air Curtains in Refrigerated Chambers," International Refrigeration and Air-Conditioning Conference, Purdue University e-Pubs (July 14-17, 2008).
ASHRAE, "Room Air Distribution Equipment," in 2004 ASHRAE Handbook – HVAC Systems and Equipment (2004): p 17.8.

[903] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[904]Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year

[905] Note that Heating Days (HD) are calculated following the same approach outlined in the Cooling Days section.

= Actual, if unknown assume code baseline and assume 95% distribution efficiency. Is unknown assume 0.821.[906]

Heat Transfer Through Open Entryway without Air Curtain (Heating Season)

Q_{bc} $= (1.08\ Btu/(hr * °F * cfm)) * CFM_{tot} * (T_{ih} - T_{oh}) / (100{,}000\ Btu/therm)$

Where:

1.08 = sensible heat transfer coefficient (specific heat of air and unit conversions)

CFM_{tot} = Total air flow through entryway (cfm)

T_{ih} = Average indoor air temperature during heating season

= User input, can assume indoor heating temperature set-point

T_{oh} = Average outdoor temp during heating season (°F)

= use table below, based on binned data from TMY3 & balance point temperature:

	Avg Outdoor Air Temp - Heating Season				
Climate Zone -Weather Station/City	**45 °F**	**50 °F**	**55 °F**	**60 °F**	**65 °F**
1 - Rockford AP / Rockford	26.3	28.8	31.6	34.2	37.3
2 - Chicago O'Hare AP / Chicago	29.4	31.2	34.0	36.8	40.3
3 - Springfield #2 / Springfield	29.4	31.5	34.6	37.7	41.6
4 - Belleville SIU RSCH / Belleville	31.7	33.6	36.2	39.2	42.3
5 - Carbondale Southern IL AP / Marion	32.5	34.9	37.8	40.7	44.0

The total airflow through the entryway, CFM_{tot}, includes both infiltration due to wind as well as thermal forces, as follows:

CFM_{tot} $= \sqrt{[(CFM_w)2 + (CFM_{t2})]}$

Where:

CFM_w = Infiltration due to the wind (cfm)

CFM_t = Infiltration due to thermal forces (cfm)

The infiltration due to the wind is calculated as follows:

CFM_w = (v_{wh} * C_{wh}) * C_v * A_d * (88 fpm/mph)

Where:

v_{wh} = average wind speed during the heating season (mph)

= similar to cooling season wind speed assumptions, use the following table to determine average wind speed based on entryway orientation:

	Entryway Orientation			
Climate Zone -Weather Station/ City	**N**	**E**	**S**	**W**
1 - Rockford AP / Rockford	5.0	4.6	4.9	5.6
2 - Chicago O'Hare AP / Chicago	5.5	5.2	4.9	5.1
3 - Springfield #2 / Springfield	5.0	4.9	5.3	5.1

[906] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

	Entryway Orientation

C_{wh} = wind speed correction factor due to wind direction in heating season, (%)

= because wind direction is not constant, a wind speed correction factor is used to adjust for time during the heating season that prevailing winds can be expected to impact the entryway. Use the following table to determine the correct wind speed correction factor for heating applications.

	Entryway Orientation			
Climate Zone -Weather Station/ City	N	E	S	W
1 - Rockford AP / Rockford	0.18	0.13	0.30	0.31
2 - Chicago O'Hare AP / Chicago	0.21	0.10	0.26	0.39
3 - Springfield #2 / Springfield	0.21	0.14	0.27	0.34
4 - Belleville SIU RSCH / Belleville	0.31	0.15	0.22	0.29
5 - Carbondale Southern IL AP / Marion	0.31	0.11	0.27	0.18

Note that correction factors do not add up to 1 (100%). This is attributed to periods of calm winds.

C_v = effectiveness of openings,

= 0.3, assumes diagonal wind[907]

A_d = area of the doorway (ft^2)

= user input

The infiltration due to thermal forces is calculated as follows:

$CFM_t = A_d * C_{dh} * (60\ sec/min) * \sqrt{[2 * g * H/2 * (T_{ih} - T_{oh}) / (459.7 + T_{ih})]}$

Where:

C_{dh} = the discharge coefficient during the heating season

= $0.4 + 0.0025 * |T_{ih} - T_{oh}|$

= 0.49, Illinois average at indoor air temp of 72°F

Note, values for C_{dh} show little variation due to balance point temperature, indoor air temperature, and climate zone. As such, if estimating results, the Illinois average value may be used as a simplification.

g = acceleration due to gravity

= 32.2 ft/sec^2

H = the height of the entryway (ft)

= user defined

Heat Transfer Through Open Entryway without Air Curtain (Heating Season)

$Q_{ac} = Q_{bc} * (1 - E)$

Where:

E = the effectiveness of the air curtain (%)

[907] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): p 16.13

= 0.60[908]

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

The air curtain would need to be regularly serviced and commissioned to ensure that it is appropriately operating. This is estimated at a cost of $150.[909]

MEASURE CODE: CI-HVC-AIRC-V08-260101

REVIEW DEADLINE: 1/1/2027

[908] Assumed conservative estimate based on referenced study results and ASHRAE 2004 effectiveness range of 60-80% for air curtains. Jaramillo, Julian, et. Al. "Application of Air Curtains in Refrigerated Chambers," International Refrigeration and Air-Conditioning Conference, Purdue University e-Pubs (July 14-17, 2008).
ASHRAE, "Room Air Distribution Equipment," in 2004 ASHRAE Handbook – HVAC Systems and Equipment (2004): p 17.8.
[909] Assumes approximately 1 hour of maintenance (include cleaning out filters, greasing, and checking that the designed angle of attack on the blower nozzle is at the designed position) based on manufacturer input and product spec sheets.

4.4.34 Destratification Fan

DESCRIPTION

This measure applies to buildings with high bay ceiling construction without fans currently installed for the purpose of destratifying air. There is also a separate measure for destratification fans as applied to agricultural settings ("High Volume Low Speed Fans"). All other destratification fan applications require custom analysis.

Air stratification leads to higher temperatures at the ceiling and lower temperatures at the ground. During the heating season, destratification fans improve air temperature distribution in a space by circulating warmer air from the ceiling back down to the floor level, thereby enhancing comfort and saving energy. Energy savings are realized by a reduction of heat loss through the roof-deck and walls as a result of a smaller temperature differential between indoor temperature and outdoor air.

Note that further, but limited, empirical evidence suggests that improved air mixing due to destratification would also result in shorter heating system runtimes due to warmer air reaching the thermostat level sooner, and possibly even allow a facility to lower the thermostat set point while maintaining a similar level of occupant comfort. This is supported by measured data in which an increase in temperatures was observed at the thermostat (5 foot level) level when air is destratified, resulting in an approximate temperature increase at the 5 foot level in the range of 1 – 3°F.[910] This measure does not currently attempt to quantify the potential impacts of air mixing from destratification; however, it should be noted that additional therms savings may be possible.

This measure was developed to be applicable to the following program types: NC, RF. If applied to other program types, the measure savings should be verified.

Limitations

- For use in conditioned, high bay structures. Recommended minimum ceiling height of 20 ft.
- This measure should only be applied to spaces in which the ceiling is subject to heat loss to outdoor air (i.e., single story or top floor spaces) and where there is sufficient space to allow for appropriate spacing of the fans. Other applications require custom analysis.
- Installation must follow manufacturer recommendations sufficient to effectively destratify the entire space. Please see calculation of effective area, Aeff, in the therms savings algorithm as a check if this criteria is met. Otherwise, custom calculation is necessary.
- Measure does not currently support facilities with night setbacks on heating equipment. Custom analysis is needed in this case.
- Certain heating systems may not be a good fit for destratification fans, such as locations with: high velocity vertical throw unit heaters, radiant heaters, and centralized forced air systems. In these cases, measured evidence of stratification should be confirmed, and custom analysis may be necessary.

DEFINITION OF EFFICIENT EQUIPMENT

High Volume, Low Speed (HVLS) fans with a minimum diameter of 14 ft with Variable Speed Drive (VSD) installed.[911]

Note that bell-shaped fans are currently excluded from this measure due to limited validation of the technology available. Further verification of effectiveness compared to HVLS is needed. A manufacturer of bell-shaped fans indicates that four bell-shaped fans provide an equivalent effective area as a typical HVLS fan. However, there is a need for further review of bell-shaped fan field test data supporting manufacturer claims regarding comparable effectiveness to HVLS technologies.

DEFINITION OF BASELINE EQUIPMENT

No destratification fans or other means to effectively mix indoor air.

[910] Kosar, Doug, "1026: Destratification Fans – Public Project Report," Nicor Gas, Emerging Technology Program (Oct 2014): 16.
[911] Kosar, Doug, "1026: Destratification Fans – Public Project Report," Nicor Gas, Emerging Technology Program (Oct 2014): 16.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[912]

DEEMED MEASURE COST

The incremental measure cost = [equipment cost of HVLS fans] + [installation costs (including materials and labor)]

Since installation cost is dependent on a variety of factors, actual costs should be used if known. The default incremental measure cost for HVLS fans are as follows:[913]

Fan Diameter (ft)	Incremental Cost
14	$6,600
16	$6,650
18	$6,700
20	$6,750
22	$6,800
24	$6,850

LOADSHAPE

Loadshape C04: Commercial Electric Heating.

COINCIDENCE FACTOR

There are no summer coincident peak demand savings for this measure due to no savings attributable to cooling during the summer peak period.

Algorithm

CALCULATION OF SAVINGS

The following formulas provide a methodology for estimating heating load savings associated with destratification fan use. This algorithm is based on the assumption that savings are directly related to the difference in heat loss through the envelope before and after destratification.

ELECTRIC ENERGY SAVINGS

The algorithm for this measure was developed for natural gas heating applications, however, for electric heating applications, the same methodology presented in the Fossil Fuel Savings Section may be used with the standard conversion factor from therms to kWh of 29.31 kWh/therm and an equipment efficiency as follows:

System Type	Cooling Capacity of Equipment	Age of Equipment	HSPF Estimate	η (Effective COP Estimate) (HSPF/3.413) * 0.95 (Distribution efficiency)
Heat Pump[914]	All	Before 2009	6.8	1.9

[912] Consistent with both 2008 Database for Energy-Efficient Resources, EUL/RUL (Effective/Remaining Useful Life) Values, October 10, 2008 and GDS Associates, Inc, "Measure Life Report: Residential and Commercial/Industrial Lighting and HVAC Measures," New England Stat Program Working Group (June 2007), p30.

[913] Costs were obtained from manufacturer interviews and are based off of average or typical prices for base model HVLS fans. Costs include materials and labor to install the fans and tie fans into an existing electrical supply located near the fan.

[914] Minimum heating efficiency standards for heat pumps are sourced from the Code of Federal Standards for Small and Large Commercial Package Air Conditioning and Heating Equipment (Air Cooled), 10 CFR 431.97 with compliance dates of June 16, 2008; January 1, 2010; January 1, 2017; January 1, 2018; and January 1, 2023. As the first federal appliance standards for heating efficiency for commercial heat pumps went into effect in June 2008, assuming efficiency standards equivalent to residential heat pumps prior to that date. Note, new Federal Standards affecting heat pumps became effective January 1, 2023.

System Type	Cooling Capacity of Equipment	Age of Equipment	HSPF Estimate	η (Effective COP Estimate) (HSPF/3.413) * 0.95 (Distribution efficiency)
	< 65,000 Btu/h	2009 - 2017	7.7	2.2
		2017 on	8.2	2.3
	≥ 65,000 Btu/h and < 135,000 Btu/h	2010 -2023	11.3	3.1
		2023 on	11.6	3.2
	≥ 135,000 Btu/h and < 240,000 Btu/h	2010-2023	10.9	3.0
		2023 on	11.3	3.1
	≥ 240,000 Btu/h and < 760,000 Btu/h	2010 on	10.9	3.0
Resistance	N/A	N/A	N/A	1

Regardless of how the building is heated, the energy consumption of the fans must be accounted for. If the building is electrically heated, fan energy shall be subtracted from the savings as calculated above. If the building is heated with natural gas, this shall represent an electric penalty, i.e., an increase in consumption. This is calculated as follows:

ΔkWh $= -(W_{fan} * N_{fan}) * t_{eff}$

W_{fan} = fan input power (kW)

N_{fan} = number of fans

t_{eff} = effective annual operation time, based on balance point temperature (hr)

= see table below in Fossil Fuel Savings section for further detail

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

ΔTherms $= [(\Delta Q_r + \Delta Q_w) * t_{eff}] / (100{,}000 * \eta)$

Where:

ΔQ_r = the heat loss reduction through the roof due to the destratification fan (Btu/hr)

= See calculation section below

ΔQ_w = the heat loss reduction through the exterior walls due to destratification fan (Btu/hr)

= See calculation section below

t_{eff} = effective annual operation time, based on balance point temperature (hr)

= use table below to select an appropriate value:[915]

In order to allow for existing inventory meeting the previous federal standards to clear shelves, this measure characterization will incorporate these federal appliance standards as an equipment efficiency option on January 1, 2024. If the application of this measure is in a new construction building, the HVAC equipment efficiency should be sourced from the applicable code edition of IECC. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints. Note, IECC 2021 is effective statewide as of 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code.

[915] These were calculated at various base temperatures using TMY3 data and adjusted to make consistent with the 30 year normal data used elsewhere. For more information see 'Destratification Fan Workpaper'; Robert Irmiger, Gas Technology Institute, 9/6/2015.

Climate Zone -Weather Station/City	t_{eff}				
	45 °F	50 °F	55 °F	60 °F	65 °F
1 - Rockford AP / Rockford	3810	4226	4880	5571	6436
2 - Chicago O'Hare AP / Chicago	3593	3986	4603	5254	6070
3 - Springfield #2 / Springfield	3038	3370	3891	4442	5131
4 - Belleville SIU RSCH / Belleville	2243	2488	2873	3280	3789
5 - Carbondale Southern IL AP / Marion	2271	2519	2909	3320	3836

100,000 = conversion factor (1 therm = 100,000 Btu)

η = thermal efficiency of heating equipment * distribution efficiency

= Actual, if unknown assume code baseline and assume 95% distribution efficiency. If unknown, assume 0.821.[916]

For example, for a warehouse facility located in Rockford, IL, installing destratification fans could reduce heat loss through the roof of 95,000 Btu/hr and a reduced heat loss through the wall of 51,228 Btu/hr. Assuming a balance point of 55°F the therms savings for the facility would be estimated as:

ΔTherms = $[(\Delta Q_r + \Delta Q_w) * t_{eff}] / (100{,}000 * \eta)$

= [(95,000 Btu/hr + 51,282 Btu/hr) * 4,880 hr] / [(100,000 Btu/therm) * 0.8)]

= 8,923 therms

Heat loss reduction through the roof

ΔQ_r = $Q_{r,s} - Q_{r,d}$

= $(1/R_r) * A_r * [(T_{r,s} - T_{oa}) - (T_{r,d} - T_{oa})]$

= $(1/R_r) * A_r * (T_{r,s} - T_{r,d})$

Where:

$Q_{r,s}$ = roof heat loss for stratified space

$Q_{r,d}$ = roof heat loss for destratified space

R_r = overall thermal resistance through the roof (hr · ft^2 · °F / Btu)

= Actual or estimated based on construction type. If unknown, assume the following:

Thermal Resistance Factor (R-Factor) for Roof	Retrofit[917]	New Construction[918]
R_r	15.0 (hr · ft^2 · °F / Btu)	30.0 (hr · ft^2 · °F / Btu)

A_r = roof area (ft^2)

= user input

[916] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

[917] Professional judgement was used to address older vintage structures and an estimate of 50% of current code standard was used.

[918] Consistent with IECC 2015/2018/2021 code requirements.

= can be approximated with floor area

T_{oa} = outside air temperature, note: therm savings calculations are actually independent of outside air because this term drops out of the heat loss reduction equation

$T_{r,s}$ = indoor temperature at roof deck, stratified case (°F)

= Actual. If unknown, use the following equation

= $m_s * h_r + T_{f,s}$

h_r = ceiling height/roof deck (ft)

m_s = estimated heat gain per foot elevation, stratified case (°F/ft)

= 0.8 °F/ft

= Professional judgement used to define value based on result from a Nicor Gas ETP Pilot field testing results and the Ansley article below.[919,920] Estimates from these sources fall on the conservative side of the industry rule of thumb range of 1-2 °F/ft heat gain.

$T_{f,s}$ = estimated floor temperature, stratified case (°F)

= $T_{tstat} – m_s * h_{tstat}$

= $T_{tstat} – 4$ °F

T_{tstat} = temperature set point at the thermostat

h_{tstat} = vertical distance between the floor and the thermostat, assumed 5ft

$T_{r,d}$ = indoor temp at roof, destratified case

= actual value, or may be estimated using the following:[921,922]

= T_{tstat} + 1 °F

For example, for a 50,000 ft^2 warehouse built in 1997 with 30 ft ceilings and a thermostat set point of 65°F. No further measured values available.

$\Delta Q_r = (1/R_r) * A_r * (T_{r,s} – T_{r,d}) = (1/R_r) * A_r * [(m_s * h_r + T_{tstat} – 4\ °F) – (T_{tstat} + 1\ °F)]$

$= (1/R_r) * A_r * [(0.8°F/ft * h_r) – 5\ °F]$

$= 1/(10\ hr \cdot ft^2 \cdot °F / Btu) * (50{,}000\ ft^2) * [(0.8°F/ft * 30\ ft) – 5\ °F]$

= 95,000 Btu/hr

Heat loss reduction through exterior walls

Note: a conservative estimate for therms savings would neglect the impact of heat loss through the walls. However, Ansley suggests that estimates based on the roof deck losses alone underestimate actual savings by up to 46%.[923]

$\Delta Q_w = Q_{w,s} - Q_{w,d}$

$= (1/R_w) * A_w * (T_{w,s} - T_{w,d})$

[919] Kosar, Doug, "1026: Destratification Fans – Public Project Report," Nicor Gas, Emerging Technology Program (Oct 2014): 10-11. Field testing results indicated approximately 0.6 °F/ft for a garden center.
[920] Aynsley, Richard, "Saving Heating Costs in Warehouses," ASHRAE Journal (Dec 2005): 48. Identifies a 0.8 °F/ft gain.
[921] Kosar, Doug, "1026: Destratification Fans – Public Project Report," Nicor Gas, Emerging Technology Program (Oct 2014): 10-11. Field testing results indicated approximately 0.6 °F/ft for a garden center.
[922] Aynsley, Richard, "Saving Heating Costs in Warehouses," ASHRAE Journal (Dec 2005): 48.
[923] Aynsley, Richard, "Saving Heating Costs in Warehouses," ASHRAE Journal (Dec 2005): 51.

Where:

R_w = overall thermal resistance through the exterior walls (hr · ft^2 · °F / Btu)

= Actual or estimated based on construction type.[924] If unknown, assume the following:

Thermal Resistance Factor (R-Factor) for Wall	Retrofit[925]	New Construction[926] (2010 or newer)
R_w	6.5 (hr · ft^2 · °F / Btu)	13.0 (hr · ft^2 · °F / Btu)

A_w = area of exterior walls (ft^2)

= user input

$T_{w,s}$ = average indoor air temperature for wall heat loss, stratified case

= If actual $T_{r,s}$ measurement is available[927]

= $[(T_{r,s} * h_a) + (T_{tstat} * h_b)] / h_r$

h_a = vertical distance between the heat source and the ceiling

h_b = vertical distance between the floor and the heat source

= Otherwise, use the linear stratification equation at average space height, see definition above.

= $m_s * (h_r / 2) + T_{f,s}$

= $m_s * (h_r / 2) + (T_{tstat} – 4)$

$T_{w,d}$ = average indoor air temperature for wall heat loss, destratified case

= $T_{tstat} + 0.5$

= conservative estimate using engineering judgment based on the same assumption used for $T_{r,f}$ estimate.

For example, for a 50,000 ft^2 warehouse built in 1997 with 1200 ft length of perimeter wall and 30 ft ceilings and a thermostat set point of 65°F and a measured temperature at the ceiling of 85°F and unit heaters located 10 feet from the roof:

ΔQ_w = $(1/R_w) * A_w * (T_{w,s} – T_{w,d})$

= $(1/R_w) * A_w * [([(T_{r,s} * h_a) + (T_{tstat} * h_b)] / h_r) – (T_{tstat} + 0.5\ °F)]$

= 1/(6.5 hr·ft^2·°F/Btu) * (1,200 * 30) * [([(85°F * 10ft) + (65°F * 20ft)] / 30ft) – (65 + 0.5 °F)]

= 1/(6.5 hr·ft^2·°F/Btu) * (36,000ft^2) * (71.7 °F – 65.5 °F)

= 34,338 Btu/hr

Measure eligibility check

[924] Because heat loss through the walls is estimated using the average space temperature pre- and post- destratification. There are a number of factors that can impact the average space temperature causing deviations from estimates of many degrees in some cases. As such, it is recommended that a conservative value for the thermal resistance through the walls, R_w, be used. A recommended method for determining R_w would be to use the highest R-value for the wall space, neglecting lower R-values associated with windows, thermal bridges, etc.

[925] ANSI/ASHRAE/IESNA 100-1995, "Energy Conservation in Existing Buildings," ASHRAE Standard (1995). Additionally, professional judgement was used to address older vintage structure prior to adoption of the 1995 standard and an estimate of 50% of current code standard was used.

[926] ANSI/ASHRAE/IESNA Standard 90.1-2007, "Energy Standard for Buildings Except Low-Rise Residential Buildings," ASHRAE Standard (2007): Table 5.5-4 and Table 5.5-5.

[927] Aynsley, Richard, "Saving Heating Costs in Warehouses," ASHRAE Journal (Dec 2005): 48.

Use the following algorithm to verify a fan system is sufficiently sized to destratify air across the entire area.

Effective area, A_{eff}, is the area over which a fan or a group of fans can be expected to effectively destratify a space. If A_{eff} is less than the roof area, A_r, a custom analysis approach should be followed to account for the change in the effectiveness of the system. In lieu of more detailed studies, effective area is defined based on the measured results from an Enbridge Gas field study in which the area a fan was expected to effectively destratify was equal to 5 times the fan diameter.[928] Effective area, is calculated as follows:

$$A_{eff} = [\pi * (5 * D_{fan})2) / 4] * N_{fan}$$

$$= 6.25 * \pi * D_{fan^2} * N_{fan}$$

Where:

A_{eff} = the effective area fan area on the floor (ft^2)

D_{fan} = fan diameter

N_{fan} = the number of fans

4.4.35 Economizer Repair and Optimization

DESCRIPTION

Economizers are designed to use unconditioned outside air (OA) instead of mechanical cooling to provide cooling when exterior conditions permit. When the OA temperature is less than the changeover temperature (determined by a static setpoint or a reference return air sensor) up to 100% OA is supplied to help meet the facility's cooling needs, thus reducing mechanical cooling energy and saving energy. An economizer that is not working or is not properly adjusted can waste energy and cause comfort issues. This HVAC measure involves the repair and optimization of common economizer problems such as adjusting changeover setpoint, repairing damper motors and linkages, and replacing non-working sensors and/or controllers. These repairs and adjustments result in proper operation which maximizes both occupant comfort and energy savings.

This measure is only appropriate for single zone packaged rooftop units. Custom calculations are required for savings for multi-zone systems.

In general, the HVAC Economizer Optimization measure may involve both repair and/or optimization, as below.

Economizer Repair – The economizer repair work is preformed to ensure that the existing economizer is working properly. This allows the system to take advantage of free cooling and ensure that the system is not supplying an excess amount of OA during non-economizing periods.

- **Replace Damper Motor** – If the existing damper motor is not operational, the unit will be replaced with a functioning motor to allow proper damper modulation.
- **Repair Damper Linkage** – If the existing linkage is broken or not adjusted properly, the unit will be replaced or adjusted to allow proper damper modulation.
- **Repair Economizer Wiring** – If the existing economizer is not operational due to a wiring issue, the issue will be repaired to allow proper economizer operation.
- **Reduce Over Ventilation** – If the unit is supplying excess OSA, the OSA damper position will be adjusted to meet minimum ventilation requirements.
- **Replace Economizer Sensor**– If the unit is equipped with a nonadjustable dry bulb (i.e., snapdisk) or malfunctioning analog sensor, the sensor is replaced with a new selectable sensor.
- **Replace Economizer Control**– If the existing economizer controller is not operational, the unit will be replaced or upgraded to allow for proper economizer operation.

Economizer Optimization – The economizer optimization work is performed to ensure that the existing economizer system is set up properly to maximize use of free cooling for units located in a particular climate zone.

- **Economizer Changeover Setpoint Adjustment** – If the unit is equipped with a fully operational economizer, the controller is adjusted to the appropriate changeover setpoint based on ASHRAE 90.1 (Figure 1 - *Table 6.5.1.1.3 High-Limit Shutoff Control Settings for Air Economizers)* for the corresponding climate zone.
- **Enable Integrated Operation** – If the unit is equipped with a fully operational economizer and is not set up to allow a minimum of two stages of cooling (1st stage – Economizer Only & 2nd Stage – Economizer & Mechanical cooling), the unit will be wired to allow two stage cooling

This measure was developed to be applicable to the following program types: RF, DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment condition is defined by fully functional economizer that is programmed to meet ASHRAE 90.1 economizer changeover setpoint requirements for the facility's climate zone and changeover control type (Figure 1 - Table 6.5.1.1.3 High-Limit Shutoff Control Settings for Air Economizers).[929]

Figure 1 – Baseline ASHRAE High-Limit Shutoff Control Settings

TABLE 6.5.1.1.3 High-Limit Shutoff Control Settings for Air Economizers[b]

Control Type	Allowed Only in Climate Zone at Listed Setpoint	Required High-Limit Setpoints (Economizer Off When):	
		Equation	Description
Fixed dry-bulb temperature	1b, 2b, 3b, 3c, 4b, 4c, 5b, 5c, 6b, 7, 8	$T_{OA} > 75°F$	Outdoor air temperature exceeds 75°F
	5a, 6a	$T_{OA} > 70°F$	Outdoor air temperature exceeds 70°F
	1a, 2a, 3a, 4a,	$T_{OA} > 65°F$	Outdoor air temperature exceeds 65°F
Differential dry-bulb temperature	1b, 2b, 3b, 3c, 4b, 4c, 5a, 5b, 5c, 6a, 6b, 7, 8	$T_{OA} > T_{RA}$	Outdoor air temperature exceeds return air temperature
Fixed enthalpy with fixed dry-bulb temperature	All	$h_{OA} > 28$ Btu/lb[a] or $T_{OA} > 75°F$	Outdoor air enthalpy exceeds 28 Btu/lb[a] of dry air[a] or outdoor air temperature exceeds 75°F
Differential enthalpy with fixed dry-bulb temperature	All	$h_{OA} > h_{RA}$ or $T_{OA} > 75°F$	Outdoor air enthalpy exceeds return air enthalpy or outdoor air temperature exceeds 75°F

a. At altitudes substantially different than sea level, the fixed enthalpy limit shall be set to the enthalpy value at 75°F and 50% RH. As an example, at approximately 6000 ft elevation, the fixed enthalpy limit is approximately 30.7 Btu/lb.
b. Devices with selectable rather than adjustable setpoints shall be capable of being set to within 2°F and 2 Btu/lb of the setpoint listed.

Figure 2 – ASHRAE Climate Zone Map

NORMATIVE APPENDIX B
CLIMATE ZONES FOR U.S. STATES AND COUNTIES

This normative appendix provides the climate zones for U.S. states and counties. Figure B-1 contains the county-level climate zone map for the United States. Table B-1 lists each state and major counties within the state and shows the climate number and letter for each county listed.

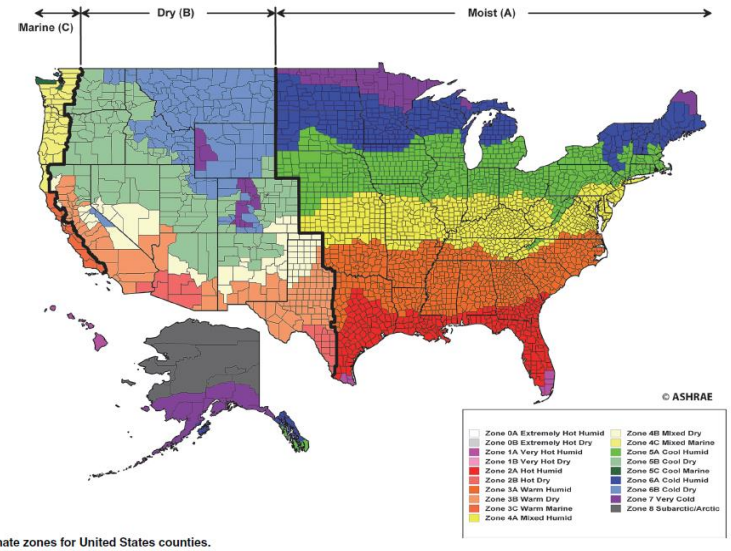

FIGURE B-1 Climate zones for United States counties.

DEFINITION OF BASELINE EQUIPMENT

The baseline for this measure is an existing economizer installed on a packaged single zone rooftop HVAC unit. The existing economizer system is currently not operating as designed due to mechanical and/or control problems, and/or is not optimally adjusted.

[929] ASHRAE, Standard 90.1-2013

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 5 years.[930]

DEEMED MEASURE COST

The cost for this measure can vary considerably depending upon the existing condition of the economizer and the work required to achieve the required efficiency levels. Measure cost should be determined on a site-specific basis.

Algorithm

CALCULATION OF ENERGY SAVINGS

The savings calculation methodology uses a regression equation to calculate the energy savings for a variety of common situations.[931] The equation variables are limited to the ranges listed; if the actual conditions fall outside of these ranges, custom calculations are required.

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = [Baseline\ Energy\ Use\ (kWh/ton) - Proposed\ Energy\ Use\ (kWh/ton)] * Cooling\ Capacity\ (Tons)$$

The following equations are used to calculate baseline and proposed electric energy use.[932]

Changeover types: Fixed Dry-Bulb (DB), Dual Temperature Dry-Bulb (DTDB), Dual Temperature Enthalpy (DTEnth), Fixed Enthalpy (Enth), and Analog ABCD Economizers (ABCD).

Electric Energy Use Equations (kWh/ton):

Building Type	Changeover Type	Equation
Assembly	DB	CZ + CSP*(-2.021) + EL*(-16.362 + OAn*1.665 + OAx*(-3.13)
	DTDB	CZ + EL*(-11.5) + OAn*1.635 + OAx*(-2.817)
	DTEnth	CZ + EL*(-17.772) + OAn*1.853 + OAx*(-3.044)
	Enth	CZ + CSP*(-5.228) + EL*(-17.475) + OAn*1.765 + OAx*(-3.003)

	ABCD	CZ + CSP*(-3.64) + EL*(-24.927) + OAn*2.09 + OAx*(-3.788)

[930] DEER 2014 (DEER2014 EUT Table D08 v2.05).

[931] For more information on methodology, please refer to workpaper submitted by CLEAResult titled "CLEAResult_Economizer Repair_151020_Finalv2.doc". Note that the original ComEd eQuest models were used in the analysis, rather than the VEIC developed models used elsewhere. VEIC do not consider this a significant issue as adjustments from the ComEd models were focused on calibrating EFLH values, not to overall energy use metrics. We also believe using the ComEd models is likely more conservative. It may be appropriate to update the analysis with the updated models at a later time.

[932] This approach allows the savings estimate to account for the operational attributes of the baseline as well as the proposed case, yielding a better estimate than an approach that assumes a particular baseline or proposed energy use to determine savings.

CSP = Economizer Changeover Setpoint (°F or Btu/lb) (actual in ranges below)

Economizer Control Type		Economizer Changeover Setpoint
Dry-Bulb		60°F – 80°F
Dual Temperature Dry-Bulb		0°F – 5°F delta
Dual Temperature Enthalpy		0 Btu/lb – 5 Btu/lb delta
Enthalpy		18 Btu/lb – 28 Btu/lb
Analog ABCD Economizers	A	73°F
	B	70°F
	C	67°F
	D	63°F
	E	55°F

EL = Integrated Economizer Operation (Economizer Lockout)

= 1 for Economizer w/ Integrated Operation (Two Stage Cooling)

= 0 for Economizer w/ out Integrated Operation (One Stage Cooling)

OAn = Minimum Outside Air (%OA * 100)[933]

= Actual. %OA must be between 15% and 70%. If unknown, assume:

- Functional Economizer – 30%
- Nonfunctional Economizer (Damper failed closed) – 15%
- Nonfunctional Economizer (Damper failed open) – 30% (assume Minimum Ventilation (Three Fingers))[934]

Note: the actual integer Oan value (e.g., 30) should be used in the regression algorithm, not the percentage (e.g., 0.3).

OAx = Maximum Outside Air (%)

= Actual. Must be between 15% and 70%. If unknown, assume:

- Functional Economizer – 70%
- Nonfunctional Economizer (Damper failed closed) – 15%
- Nonfunctional Economizer (Damper failed open) – 30% (assume Minimum Ventilation (Three Fingers))

For example, a low-rise office building in Rockford (Climate Zone 1) is heated and cooled with a packaged Gas (92 kBtu output) / DX (5 ton) RTU. The RTU is equipped with a fixed dry bulb outside air economizer and is programed for integrated operation. When the technician inspects the RTU they find that the changeover setpoint is programmed to 62°F, which does not meet ASHRAE economizer high limit shut off air economizer recommendations. After further investigation it is found that the OA damper motor is not operational and is providing 30% outside air.

The technician replaces the damper motor and allow for proper OA damper modulation (30% Min OA & 70% Max OA). They also adjust the fixed dry-bulb changeover setpoint to meet the ASHRAE economizer high limit shut off air economizer recommendation of 70°F.

ΔkWh = [Baseline Energy Use (kWh/ton) - Proposed Energy Use (kWh/ton)] * Cooling Capacity (tons)

Baseline Energy Use (kWh/ton) = Equation for Office Low Rise

= CZ + CSP*(-0.967) + EL*(-6.327) + OAn*2.87 + OAx*(-1.047)

= 674.06 + 62*(-0.967) + 0*(-6.327) + 30*2.87 + 30*(-1.047)

= 668.8 kWh/ton

Proposed Energy Use (kWh/ton) = Equation for Office Low Rise

= CZ + CSP*(-0.967) + EL*(-6.327) + OAn*2.87 + OAx*(-1.047)

= 674.06 + 70*(-0.967) + 0*(-6.327) + 30*2.87 + 70*(-1.047)

= 619.2 kWh/ton

ΔkWh = [668.8 (kWh/ton) - 619.2 (kWh/ton)] * 5 tons

= 49.6 kWh/ton * 5 tons

= 248.08 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A - It is assumed that repair or optimization of the economizer will not typically have a significant impact on summer peak demand.

For example, a low-rise office building in Rockford (Climate Zone 1) is heated and cooled with a packaged Gas (92 kBtu output) / DX (5 ton) RTU. The RTU is equipped with a fixed dry bulb outside air economizer and is programed for integrated operation. When the technician inspects the RTU they find that the changeover setpoint is programmed to 62°F, which does not meet ASHRAE economizer high limit shut off air economizer recommendations. After further investigation it is found the OA damper motor is not operational and is providing 30% outside air.

The technician replaces the damper motor and allow for proper OA damper modulation (30% Min OA & 70% Max OA). They also adjust the fixed dry-bulb changeover setpoint to meet the ASHRAE economizer high limit shut off air economizer recommendation of 70°F.

ΔTherms = [Baseline Energy Use (Therms/kBtuh) - Proposed Energy Use (Therms/kBtuh)] * Output Heating Capacity (kBtuh)

Baseline Energy Use (Therms/kBtuh) = Equation for Office Low Rise

= CZ + OAn*0.3
= 5.83 + 30*0.3
=14.8 Therms/kBtuh output

Proposed Energy Use (Therms/kBtuh) = Equation for Office Low Rise

4.4.36 Multi-Family Space Heating Steam Boiler Averaging Controls

DESCRIPTION

This measure covers multi-family space heating boiler averaging controls. Temperature sensors are placed in interior spaces to monitor the average temperature of the building. At a minimum, a sensor must be placed at each corner and at one central location. Additionally, a temperature sensor must monitor the outside air temperature. These sensors shall provide data to the averaging controls. The averaging controls will adjust the boiler operation based upon an average of the indoor sensors and the outside air temperature. These controls shall also incorporate a night-time setback capability. Buildings utilizing thermostatic radiator valves, or other modulating control valves or sequences to control the temperature in individual spaces, are not eligible.

This measure was developed to be applicable to the following program types: RF.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify the boiler(s) must incorporate an averaging control system utilizing at least 4 indoor sensors and 1 outdoor sensor. The controls shall have the capability to incorporate a nighttime setback throughout the building.

DEFINITION OF BASELINE EQUIPMENT

The baseline is a boiler system without averaging controls or other steam supply modulating controls. Current boiler control system can utilize a single thermostat or aquastat and timer.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for the domestic hot water boiler(s) is 20 years.[935]

DEEMED MEASURE COST

As a retrofit measure, the actual installed cost should be used for screening purposes. A deemed retrofit measure cost of $5,060 can be used if the actual installed cost is unknown.[936]

[936] NREL, "Steam Balancing and Tuning for Multifamily Residential Buildings in Chicagoland-Second Year of Data Collection", August 2013.

FOSSIL FUEL SAVINGS[937]

ΔTherms = $Capacity * EFLH * SF / 100{,}000$

Or

ΔTherms = $Living\ Units * Gas_Boiler_Load * HF * SF$

Where:

Capacity = Boiler gas input size (Btu/h)

= Actual

Living Units = Number of living units (apartment or condos) served by the boiler

= Actual

HF = Household factor

= 65% for multifamily[938]

Gas_Boiler_Load = Estimate of annual household load for gas boiler heated single-family homes. If location is unknown, assume the average below[939]

Climate Zone (City based upon)	Gas_Boiler_Load (therms)
1 (Rockford)	1275
2 (Chicago)	1218
3 (Springfield)	1043
4 (Belleville)	805
5 (Marion)	819
Average	1158

EFLH = Effective Full Load Hours for heating in Existing Buildings are provided in section 4.4. HVAC End Use

SF = Savings Factor

= 10.2%,[940] or custom if savings can be substantiated

[937] The preferred algorithm for determining fossil fuel savings relies on capacity of the boiler, this algorithm is more closely aligned with how similar measures in the TRM calculate fossil fuel savings. The algorithm that uses Living Units to estimate savings exists as an option for when the capacity of the existing boiler is unknown.

[938] Multifamily household heating consumption relative to single-family households is affected by overall household square footage and exposure to the exterior. This 65% reduction factor is applied to MF homes, based on professional judgment that average household size, and heat loads of MF households are smaller than single-family homes

[939] Values are based on household heating consumption values and inferred average AFUE results from Table 3-4, Program Sample Analysis, *Nicor R29 Res Rebate Evaluation Report 092611_REV FINAL to Nicor*). Adjusting to a statewide average using relative HDD values to adjust for the evaluation results focus on northern region. Values for individual cities are then calculated by comparing average HDD to the individual city's HDD.

[940] "Steam Balancing and Tuning for Multifamily Residential Buildings in Chicagoland-Second Year of Data Collection", NREL, August 2013, states that test buildings with steam balancing measures saved an average of 10.2%. The energy savings estimate assumes additional system balancing through the installation of large capacity air vents on steam main lines and the replacement of radiator vents. This work is assumed to be done in concert with any system being retrofitted with averaging controls.

100,000 = converts Btu/h to therm

For example, a 1,000,000 btu/h steam boiler in a Mid-Rise Multi-Family building in Chicago has averaging controls installed.

ΔTherms = 1,000,000 * 1,685 * 0.102 / 100,000

= 1,719 therms

4.4.37 Unitary HVAC Condensing Furnace

DESCRIPTION

Condensing furnaces recover energy in combustion exhaust flue gasses that would otherwise simply be vented to the atmosphere, making them more efficient than non-condensing furnaces. This measure applies to a constant volume (CV), dedicated outside air system (DOAS), make-up air system (MUAS), or any unitary HVAC system that is utilizing an indirect gas fired process to heat 100% OA to provide ventilation or make-up air to commercial and industrial (C&I) building spaces. The unitary package must contain an indirect gas-fired, warm air furnace section, but the unitary package can be with or without an electric air conditioning section. The unitary package can be either a single package or split system that is applied indoors (non-weatherized) or outdoors (weatherized).

This measure excludes demand control ventilation, condensing unit heaters, and high efficiency (condensing) furnaces with annual fuel utilization efficiency (AFUE) ratings (for furnaces with less than 225,000 Btu/hr input capacity), which are covered by other measures for the C&I sector in the Technical Reference Manual (TRM).[941]

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the efficient unitary equipment must contain a condensing, warm air furnace with a natural gas thermal efficiency (TE) rating of 90% or higher, or alternatively, the unitary package must have equipment nameplate information for natural gas that identifies a heating output and heating input rating that has an output over input ratio of 0.90 or higher. These ratings must be certified by a recognized testing laboratory in accordance with American National Standards Institute (ANSI) Standard Z21.47 for Gas-Fired Central Furnaces.[942] The furnace must be vented and condensate disposed of in accordance with the equipment manufacturer installation instructions and applicable codes.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is expected to be unitary equipment that contains a non-condensing, warm air furnace with a natural gas thermal efficiency (TE) rating of 81%, or alternatively, the unitary package will have equipment nameplate information for natural gas that identifies a heating output and heating input rating that has an output over input ratio of 0.81. These ratings must be certified by a recognized testing laboratory in accordance with American National Standards Institute (ANSI) Standard Z21.47 for Gas-Fired Central Furnaces. Note, effective January 1, 2023, the Department of Energy (DOE) federal minimum efficiency standard is 81% for ≥225,000 Btu/hr input capacity furnaces per the Energy Conservation Standard for Commercial Warm Air Furnaces.[943] In the American Society of Heating, Refrigeration and Air-Conditioning Engineers (ASHRAE) Standard 90.1 Energy Standard for Buildings Except Low-Rise Residential Buildings[944] that minimum TE requirement is extended below 225,000 Btu/hr input capacity to require all commercial warm air furnaces and combination warm air furnace/air conditioning units to meet the minimum 81% TE.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years[945], which is consistent with the established TRM measure life for single-package and split system unitary air conditioners, since in colder climates these unitary packages typically contain a gas-fired, warm air furnace section, with an electric air conditioning section.

[945] Minnesota Department of Commerce, Division of Energy Resources, Field Study of Condensing Hating in Makeup-Air and Mixed-Air Rooftop Units (RTUs), GTI, October 2017

DEEMED MEASURE COST

The actual incremental equipment and installation costs should be used, if available. If not, the incremental cost of $5.42 per 1000 Btu/hr of output capacity should be used for the condensing furnace equipment (as part of a unitary package) and its installation (including the combustion condensate drainage and disposal system). This incremental cost is from the DOE Technical Support Document for the Notice of Proposed Rulemaking (NOPR) for the Commercial Warm Air Furnace Standard.[946] Per the DOE documentation, it is based on their representative 250,000 Btu/hr input capacity furnace at a 92% TE.

LOADSHAPE

Loadshape C23 - Commercial Ventilation

COINCIDENCE FACTOR

The coincidence factor is assumed to be 1.0 – that is, building ventilation will always be provided during peak periods.

Algorithm

CALCULATION OF SAVINGS

The following methodology provides formulas for estimating gas heating savings associated with condensing furnaces in unitary HVAC packages when applied as a CV, DOAS, MUAS, or any RTU that is indirectly heating 100% outside air (OA). These types of HVAC systems typically run continuously during the HVAC operating schedule to provide building ventilation and maintain indoor air quality or to compensate for exhaust and maintain neutral or slightly positive building pressurization. The algorithm estimates the gas use reduction resulting from utilizing condensing heating of 90% or higher thermal efficiency (TE) in place of the federal minimum TE of 80% (or other user defined baseline TE) for commercial warm air furnaces.

The methodology provides a representative group of operating schedules for the market sector applications highlighted earlier based on DOE commercial reference building models.[947] Heating loads during the operating schedule are determined based on hourly differences between a range of supply air (SA) heated to temperatures and the OA temperature using Typical Meteorological Year (TMYx) weather data.[948] These hourly heating loads are generated for all hours when the OA temperature is below the base temperature of 55 °F for heating in C&I settings per the TRM. To accommodate the variability in heating base temperatures in C&I settings, these hourly heating loads are also generated for base temperatures of 45 °F and 65 °F for heating. The hourly heating loads are then summed for the entire year. The annual heating loads are calculated in this manner for the climate zone 2 weather station (Chicago O'Hare Airport), which is then normalized to its National Centers for Environmental Information (NCEI)[949] 15-year (2006-2020) weather average by multiplying by the heating degree day (HDD) ratio of the NCEI/TRM HDD55 over the TMYx HDD55 (HDD at base temperature of 55 °F), and likewise for the annual heating loads for HDD45 (HDD at base temperature of 45 °F) and HDD65 (HDD at base temperature of 65 °F), using the values in Table 1 and Table 2. Since detailed hourly weather data is not available for all 5 of the TRM climate zone weather stations, the annual heating loads for the other climate zones are determined by multiplying the climate zone 2 annual heating loads by the ratio of the other climate zone NCEI HDD over the climate zone 2 NCEI HDD, using the values in Table 1.

These annual heating loads on a per unit airflow basis are then used in conjunction with the actual airflow of the 100% OA system and its condensing efficiency to calculate the gas heating savings versus the baseline (non-condensing) heating efficiency. This measure results in additional electric use by the unitary HVAC package due to the additional pressure drop of the condensing heat exchanger of the warm air furnace section.

2 - Chicago O'Hare AP / Chicago	2093	3855	6086

ELECTRIC ENERGY SAVINGS

As noted previously, this measure results in additional SA fan electric use by the unitary HVAC system due to the additional pressure drop of the condensing heat exchanger of the warm air furnace section.

ΔkWh $= -(t_{FAN} * cfm * \Delta P) / (\eta_{FAN/MOTOR} * 8520)$

Where:

t_{FAN} = annual fan runtime (hr), refer to Tables 3 through 14

cfm = airflow (cfm), use actual or rated system airflow

ΔP = incremental pressure drop (inch W.G.), assume 0.15 if actual value not known

$\eta_{FAN/MOTOR}$ = combined fan and motor efficiency, assume 0.60 if actual value not known

8520 = conversion factor (fan horsepower – HP – calculation constant of 6356 for standard air conditions adjusted by 1 HP = 0.746 kW, or 6356/ 0.746 = 8520 for this kW calculation)

SUMMER COINCIDENT PEAK DEMAND SAVINGS

The additional SA fan electric use by the unitary HVAC system will typically result in a modest electric demand increase.

ΔkW $= (\Delta kWh / t_{FAN}) * CF$

Where:

CF = 1.0

For example, for a "big box" retail store operating 24 hours a day and 7 days a week (8760 hours per year) with a 5000 cfm DOAS that has an incremental pressure drop of 0.15 inch W.G. and a combined fan and motor efficiency of 0.6 has annual kWh savings of:

ΔkWh = - (t_{FAN} * cfm * ΔP) / ($\eta_{FAN/MOTOR}$ * 8520)
= - (8760 * 5000 * 0.15) / (0.6 * 8520)
= - 1285 kWh

ΔkW = (ΔkWh / t_{FAN}) * CF
= (- 1285 / 8760) * 1.0
= - 0.15 kW

FOSSIL FUEL SAVINGS

ΔTherms = $[Q_{OA} * cfm * (1/TE_{NC} - 1/TE_C)]/ 100{,}000$

Where:

Q_{OA} = annual outside air (OA) heating load per cfm of OA (Btu/cfm)

First, select the most representative operating schedule for the application from among the four (4) scenarios listed below and its set of three (3) applicable tables. Second, select the table in that set with the most representative HDD base temperature – the base temperature for OA below which heating is required. If that base temperature is not readily determined, select the TRM default base temperature of 55 °F (HDD55) for heating in C&I settings. Third, select the climate zone within that table. Fourth, select an appropriate heated to supply air (SA) temperature within that table. Use the resulting Q_{OA} value, with linear interpolation allowed between SA temperatures.

The four (4) scenarios available are indicative of the following building applications and operating schedules:

1. 24 hour a day and 7 day a week (24/7) operation, with HVAC operating schedule of 8760 hours per year, typical of large retail stores with DOAS, hotel/multifamily buildings with corridor MUAS, and healthcare facilities with DOAS. Use Table 3 through Table 5.

2. 6:00 AM to 1:00 AM everyday operation, with HVAC operating schedule of 7300 hours per year, typical of full service and quick service restaurants with kitchen MUAS. Use Table 6 through Table 8.

3. 7:00 AM to 9:00 PM Monday-Friday, 7:00 AM to 10:00 PM Saturday, and 9:00 AM to 7:00 PM Sunday operations, with HVAC operating schedule of 5266 hours per year, typical of non-24/7 retail stores with DOAS. Use Table 9 through Table 11.

4. 7:00 AM to 9:00 PM Monday-Friday operation, with HVAC operating schedule of 3911 hours per year, typical of school buildings with DOAS. Use Table 12 through Table 14.

TE_{NC} = non-condensing thermal efficiency (TE), use federal minimum TE of 81% (0.81) or actual TE if known

TE_C = condensing thermal efficiency (TE), use actual TE or if unknown assume 90% (0.90)

100,000 = conversion factor (1 therm = 100,000 Btu)

Continuing the previous example: for a climate zone 2 (Chicago O'Hare AP / Chicago) application using a 90% TE condensing DOAS with a supply air temperature from the DOAS of 95 °F:

$\Delta Therms = [Q_{OA} * cfm * (1/TE_{NC} - 1/TE_C)]/ 100,000$

$= 307,374 * 5,000 * (1/0.81 – 1/0.90)/100,000$

$= 1,897$ therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

The actual incremental annual maintenance costs should be used, if available. If not, the incremental cost of $0.05 per 1000 Btu/hr of output capacity should be used for maintaining the combustion condensate disposal system yearly. This incremental cost is from the DOE Technical Support Document for the Notice of Proposed Rulemaking (NOPR) for the Commercial Warm Air Furnace Standard. Per the DOE documentation, it is based on their representative 250,000 Btu/hr input capacity furnace at a 92% TE.

MEASURE CODE: CI-HVC-DSFN-V05-240101

REVIEW DEADLINE: 1/1/2027

4.4.38 Covers and Gap Sealers for Room Air Conditioners

DESCRIPTION

Room air conditioners (window ACs, through-the-wall or sleeve ACs, PTACs or PTHPs) constitute a permanent or semi-permanent penetration through the building's envelope. These units are often poorly installed, resulting in gaps that act like air leakage pathways through the building's envelope. The uncontrolled movement of air across the gaps in the envelope (infiltration) increases the building's winter heating requirements and reduces its overall energy performance.

The heat loss and infiltration can be reduced by installing a rigid or flexible insulated cover on the inside of a room AC. These covers should be maintained by building staff and should remain installed through the heating season. Simple uninsulated cloth covers with no sealing at edges do not qualify for this measure.

There are several types of AC covers available that may be eligible for this measure:

- If the room AC is left in the window or sleeve, a rigid cover that covers the indoor side of the AC unit with foam gaskets to seal the edges may be installed.
- If the room AC is absent or is removed during the heating months, a rigid cover that fits inside the sleeve with foam gaskets along the edges for proper air sealing may be installed.
- Flexible covers that are well insulated and perfectly cover the indoor side of the AC unit may also be eligible for this measure.

This measure was developed to be applicable to the following program types: RF, DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The installed equipment is a rigid cover that fits inside the empty sleeve or completely covers the indoor side of a window AC unit, with foam gaskets sealing the edges. A flexible insulated cover that perfectly covers the indoor side of the unit and seals gaps may also be installed. Covers should remain installed throughout the winter heating season.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a room AC (window AC, through-the-wall or sleeve AC, PTAC or PTHP) that is poorly installed with gaps around the edges and does not use AC covers or gap sealers during the winter heating months.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated useful life of typical AC covers is 5 years.[950]

DEEMED MEASURE COST

The measure cost is the full cost of installing AC covers. Actual installation costs (material and labor) should be used if available. In actual costs are unknown, assume material cost of $24 (flexible covers) up to $119, depending on size of the AC unit.[951] The install time per unit is 15 to 30 minutes at assumed labor rate of $20/hour.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

If the building is electrically heated, electric energy savings are calculated as follows:

$$\Delta kWh = (Q_{infiltration} * 1.08 * (T_{SA} - T_{OA}) * EFLH_{heat}) / (3{,}412 * COP)$$

Where:

$Q_{infiltration}$ = Air infiltration (CFM) due to poor installation of window or through-the-wall AC[952]

$= ELA * 0.000645 * (f_s^2 fs2 * (T_{SA} TSA - T_{OA} TOA) + f_w^2 fw2 * U^2 U2)^{1/2} * 2118.88$

Where:

ELA = Effective Leakage Area (sq. in.)

= Can be collected on site; if unknown, assume 6 sq. in.[953]

0.000645= Converts square inches to square meters

f_s = Stack Coefficient

$=1/3 * (9.81 * Height * 0.3048 / TOA)^{0.5}$

f_w = Wind Coefficient

$= A * B * (Height * 0.3048 / 10)^C$

Where:

9.81 = Acceleration due to gravity (m/s^2)

Height = Height of the location of the leakage area in feet

= Assume 8 ft per floor

0.3048 = Converts feet to meters

T_{OA} = Average Outside Air Temperature during heating period.[954] Use values from table below, based on facility location.[955] This figure must be in Kelvin to determine Stack Coefficient (f_s) and infiltration ($Q_{infiltration}$), but in Fahrenheit to determine energy savings (ΔkWh, ΔTherms).

Zone	T_{OA} (°F)	T_{OA} (K)
Zone 1 (Rockford)	31.63	272.94
Zone 2 (Chicago)	33.99	274.26
Zone 3 (Springfield)	34.58	274.58
Zone 4 (Belleville)	36.24	275.51
Zone 5 (Marion)	39.07	277.08

[952] Infiltration equation and values for stack and wind coefficient equations from "The Use of Blower Door Data." Max Sherman, 1998. The equation is adjusted for wall leakage area (i.e. no ceiling or floor leakage).

[953] Average effective leakage area for multi-family building AC units from "There are Holes in Our Walls." Prepared for Urban Green Council by Steven Winter Associates, April 2011.

[954] "Heating Period" is defined as hours when the TMY3 dry bulb temperature is less than 55°F (balance point).

[955] Based on NREL's Typical Meteorological Year 3 (TMY3) data for different weather stations.

A, B and C = Constants based on the facility site's shielding and terrain parameters. Use values from the tables below:[956]

Shielding Class	Shielding Type	Shielding Description	A
1	None	No obstructions or local shielding whatsoever (i.e. isolated building)	0.324
2	Light	Light local shielding with few obstructions (e.g. A few trees or a shed in the vicinity)	0.285
3	Moderate	Moderate local shielding; some obstructions within two house heights (e.g. Thick hedge fence on fence and nearby building)	0.24
4	Heavy	Heavy shielding; obstructions around most of perimeter buildings or trees within five building heights in most directions (e.g. Well developed/dense tract house)	0.185
5	Very Heavy	Very heavy shielding, large obstruction surrounding perimeter within two house heights (e.g. Typical downtown area)	0.102

Terrain Class	Terrain Type	Terrain Description	B	C
1	None	Ocean or other body of eater with at least 5 km of unrestricted space	1.3	0.1
2	Light	Flat terrain with some isolated obstacles (e.g. Buildings or trees well separated from each other)	1	0.15
3	Moderate	Rural areas with low buildings, trees etc.	0.85	0.2
4	Heavy	Urban, industrial or forest areas	0.67	0.25
5	Very Heavy	Center of large city (e.g. Manhattan)	0.47	0.35

0.3048 = Converts feet to meters

T_{SA} = Average Indoor Air Temperature during heating period. This figure will need to be in Kelvin to calculate infiltration ($Q_{infiltration}$) and Fahrenheit to calculate energy savings (ΔkWh, ΔTherms).

= Collected on site. If unknown, assume 72°F (295 K). If known, convert °F to K by using the following equation: K = (°F + 459.67) * (5/9).

U = Average Wind Speed (m/s) during heating period. Use table below, based on facility location.[957]

Zone	U (m/s)
Zone 1 (Rockford)	4.50
Zone 2 (Chicago)	4.67
Zone 3 (Springfield)	4.60
Zone 4 (Belleville)	3.92
Zone 5 (Marion)	3.07

2118.88 = Converts m^3/s to CFM

1.08 = Sensible heat transfer constant (Btu/hr.CFM.°F)

[956] Shielding and terrain class descriptions and constants from "The Use of Blower Door Data." Max Sherman, 1998" and "Wind and Infiltration Interaction for Small Buildings." MH Sherman and DT Grimsrud, Lawrence Berkley Laboratory, 1982.
[957] Based on TMY3 data, see "Covers for Room AC_11092016.xls" for more information.

$EFLH_{heat}$ = Equivalent Full Load Hours for heating in Existing Buildings from section 4.4 HVAC End Use[958]

3,412 = Converts Btus to kWh

COP = Coefficient of Performance of the heating unit

= Collected on site. If unknown assume 2.6 for PTHP[959]

If the floor of the building where the AC cover was installed is known, deemed per-unit savings for the Multifamily Building type for Shielding Class 3 and Terrain Class 3 are as follows:

Multifamily - Electric Savings per Unit (kWh/unit) Floor # Where Installed is Known						
Floor # Where Installed	Height	Rockford	Chicago	Springfield	Belleville	Marion
1	8	55.18	53.16	45.70	31.09	25.67
2	16	68.19	65.31	56.17	38.72	32.66
3	24	77.92	74.34	63.96	44.45	37.97
4	32	86.04	81.85	70.44	49.25	42.44
5	40	93.15	88.42	76.11	53.46	46.37
6	48	99.56	94.34	81.22	57.26	49.93
7	56	105.44	99.76	85.90	60.75	53.20
8	64	110.91	104.80	90.25	63.99	56.24
9	72	116.04	109.53	94.33	67.04	59.11
10	80	120.89	114.00	98.19	69.92	61.81
12	96	129.92	122.31	105.36	75.29	66.85
14	112	138.21	129.94	111.95	80.22	71.49
16	128	145.93	137.04	118.08	84.81	75.82
18	144	153.19	143.72	123.84	89.13	79.88
20	160	160.05	150.03	129.29	93.21	83.72
22	176	166.59	156.03	134.47	97.10	87.38
24	192	172.83	161.77	139.42	100.82	90.88
26	208	178.82	167.28	144.18	104.38	94.23
28	224	184.58	172.57	148.75	107.81	97.46
30	240	190.15	177.69	153.17	111.12	100.58

If the floor of the building where the AC cover was installed is unknown, but the total number of floors in the building is known, assume the AC overs were installed evenly across all floors of the building. Therefore, savings is the average of the savings for each floor less than or equal to the total number of floors in the building. The deemed per-unit savings for the Multifamily Building type for Shielding Class 3 and Terrain Class 3 is:

Multifamily - Electric Savings per Unit (kWh/unit) Floor # Where Installed is not Known, But Total Building Height is Known						
# of Floors in Building	Building Height	Rockford	Chicago	Springfield	Belleville	Marion
1	8	55.18	53.16	45.70	31.09	25.67
2	16	61.69	59.24	50.94	34.91	29.17

[958] Although in theory the hours should be all hours that infiltration is expected (i.e. all hours <55F), the IL TAC has agreed to use the Equivalent Full Load Hours to keep the savings at a more conservative level.

[959] From IECC 2012 Minimum Efficiency Requirements. For a 1 ton PTHP, COP = 2.9 – (0.026 * 12,000/1,000).

Multifamily - Electric Savings per Unit (kWh/unit) Floor # Where Installed is not Known, But Total Building Height is Known						
# of Floors in Building	Building Height	Rockford	Chicago	Springfield	Belleville	Marion
3	24	67.10	64.27	55.28	38.09	32.10
4	32	71.83	68.67	59.07	40.88	34.69
5	40	76.10	72.62	62.48	43.39	37.02
6	48	80.01	76.24	65.60	45.71	39.17
7	56	83.64	79.60	68.50	47.85	41.18
8	64	87.05	82.75	71.22	49.87	43.06
9	72	90.27	85.72	73.79	51.78	44.84
10	80	93.33	88.55	76.23	53.59	46.54
12	96	96.66	91.62	78.88	55.57	48.39
14	112	100.12	94.81	81.63	57.62	50.31
16	128	103.64	98.06	84.44	59.71	52.27
18	144	107.18	101.32	87.25	61.81	54.25
20	160	110.71	104.57	90.05	63.91	56.21
22	176	114.20	107.79	92.83	65.98	58.16
24	192	117.65	110.96	95.57	68.03	60.08
26	208	121.05	114.09	98.27	70.05	61.98
28	224	124.39	117.17	100.93	72.04	63.85
30	240	127.68	120.19	103.54	73.99	65.68

For example, a mid-rise multi-family building located in the moderate terrain class and shielding class of Chicago, has 16 rooms on the 10th floor (80 feet high) with PTHPs that get covered with a cover and foam gasket during the heating months. The indoor temperature during the heating months is maintained at 74°F. The air infiltration and the related energy savings from the AC covers and seals are calculated as follows -

For Shielding Class 3 and Terrain Class 3,

A = 0.24, B = 0.85 and C = 0.2

Therefore,

$f_s = 1/3 * (9.81\ m/s^2 * 80\ ft * 0.3048\ m/ft / 274.26\ K)^{0.5} = 0.3\ m/K^{½}.s$

$f_w = 0.24 * 0.85 * (80\ ft * 0.3048\ m/ft / 10\ m)^{0.2} = 0.24$

Total effective leakage area (ELA) = 16 units * 6 sq. in. = 96 sq. in.

$Q_{infiltration} = ELA * 0.000645 * (f_s^2 * (T_{SA} – T_{OA}) + f_w^2 * U^2)^{1/2} * 2118.88$

$= 96 * 0.000645 * (0.3^2 * (296.48\ K – 274.26\ K) + 0.24^2 * 4.67^2)^{1/2} * 2118.88$

$= 237\ CFM$

$\Delta kWh = (237 * 1.08\ Btu/hr.CFM.°F * (74°F – 33.99°F) * 1,782) / (3,412\ Btu/kWh * 2.6)$

$= 2,057\ kWh$

SUMMER COINCIDENT PEAK DEMAND SAVINGS

As the savings occur during the winter season (non-peak), there are no demand savings associated with this measure.

FOSSIL FUEL SAVINGS

If the building is heated with gas, the natural gas savings are calculated as follows:

$$\Delta Therms = (Q_{infiltration} * 1.08\ Btu/hr.CFM.°F * (T_{SA} - T_{OA}) * EFLH_{heat}) / (100{,}000\ Btu/therm * \eta)$$

Where:

η = Efficiency of heating equipment.

= Collected on site. If unknown, assume 80%[960].

100,000 = Converts Btus to therms

Other factors as defined above

If the floor of the building where the AC cover was installed is known, deemed per-unit savings per unit for the Multifamily Building type for Shielding Class 3 and Terrain Class 3 are as follows:

Multifamily - Gas Savings per Unit (Therms/Unit) Floor # Where Installed is Known						
Floor # Where Installed	Height	Rockford	Chicago	Springfield	Belleville	Marion
1	8	6.12	5.90	5.07	3.45	2.85
2	16	7.56	7.24	6.23	4.29	3.62

If the floor of the building where the AC cover was installed is unknown, but the total number of floors in the building is known, assume the AC overs were installed evenly across all floors of the building. Therefore, savings is the average of the savings for each floor less than or equal to the total number of floors in the building. The deemed per-unit savings for the Multifamily Building type for Shielding Class 3 and Terrain Class 3 is:

Multifamily - Gas Savings per Unit (Therms/Unit) Floor # Where Installed is not Known, But Total Building Height is Known						
# of Floors in Building	Building Height	Rockford	Chicago	Springfield	Belleville	Marion
1	8	6.12	5.90	5.07	3.45	2.85
2	16	6.84	6.57	5.65	3.87	3.24
3	24	7.44	7.13	6.13	4.22	3.56

[960] Energy Independence and Security Act of 2007 – averaged for hot water and steam boilers.

Multifamily - Gas Savings per Unit (Therms/Unit) Floor # Where Installed is not Known, But Total Building Height is Known						
# of Floors in Building	Building Height	Rockford	Chicago	Springfield	Belleville	Marion
4	32	7.97	7.62	6.55	4.53	3.85
5	40	8.44	8.05	6.93	4.81	4.11
6	48	8.87	8.46	7.28	5.07	4.35
7	56	9.27	8.83	7.60	5.31	4.57
8	64	9.65	9.18	7.90	5.53	4.78
9	72	10.01	9.51	8.18	5.74	4.97
10	80	10.35	9.82	8.45	5.94	5.16
12	96	10.72	10.16	8.75	6.16	5.37
14	112	11.10	10.51	9.05	6.39	5.58
16	128	11.49	10.87	9.36	6.62	5.80
18	144	11.89	11.24	9.68	6.85	6.02
20	160	12.28	11.60	9.99	7.09	6.23
22	176	12.66	11.95	10.29	7.32	6.45
24	192	13.05	12.31	10.60	7.54	6.66
26	208	13.42	12.65	10.90	7.77	6.87
28	224	13.79	12.99	11.19	7.99	7.08
30	240	14.16	13.33	11.48	8.21	7.28

For example, a gas-heated mid-rise multi-family building located in the moderate terrain class and shielding class of Chicago, has 16 rooms on the 10th floor (80 feet high) with room air conditioners that get covered with an AC cover and foam gasket during the heating months. The indoor temperature during the heating months is maintained at 74°F. The air infiltration and the related therm savings from the AC covers and seals are calculated as follows:

For Shielding Class 3 and Terrain Class 3,

A = 0.24, B = 0.85 and C = 0.2

Therefore,

$f_s = 1/3 * (9.81\ m/s^2 * 80\ ft * 0.3048\ m/ft / 274.26\ K)^{0.5} = 0.3\ m/K^{½}.s$

$f_w = 0.24 * 0.85 * (80\ ft * 0.3048\ m/ft / 10\ m)^{0.2} = 0.24$

Total effective leakage area (ELA) = 16 units * 6 sq.in = 96 sq. in

$Q_{infiltration} = ELA * 0.000645 * (f_s^2 * (T_{SA} – T_{OA}) + f_w^2 * U^2)^{1/2} * 2118.88$

$= 96 * 0.000645 * (0.3^2 * (296.48\ K – 274.26\ K) + 0.24^2 * 4.67^2)^{1/2} * 2118.88$

$= 237\ CFM$

ΔTherms = (237 * 1.08 Btu/hr.CFM.°F * (74°F – 33.99°F) * 1,782) / (100,000 Btu/therm * 80%)

= 228 therms

REVIEW DEADLINE: 1/1/2028

4.4.39 High Temperature Heating and Ventilation (HTHV) Direct Fired Heater

DESCRIPTION

This measure applies to 100% outside air, high temperature heating and ventilation (HTHV) direct fired gas heaters. These units replace unit heaters (indirect gas fired or steam coil) or rooftop units in warehouses which suffer from extreme temperature stratification, minimal controls, and reduced heating efficiencies.

Warehouses have high ceilings (~30 ft high) and suffer from stratification of air. The warm air rises and remains near the roof which keeps the thermostat from reaching its desired setpoint. This increases the run hours of the heating unit and causes discomfort among the occupants. The HTHV units have high pressure fans that direct high temperature and high velocity air towards the floor to help minimize temperature stratification. On average, a 30 ft high warehouse could reduce its linear stratification from 0.53°F/ft to 0.13°F/ft, thus maintaining a more uniform temperature in the room and reducing the operating hours of the heating unit.

Since the HTHV units are direct fired, they also have improved efficiencies of 92% compared to 80% for a typical indirect fired unit heater or rooftop unit. They transfer the latent heat of the flue gases into the space instead of venting it out.

This measure only applies to high ceiling warehouses that do not have any other destratification technologies installed (e.g., destratification fans, air rotation units). New HTHV units must be the warehouse's primary heat source.

This measure was developed to be applicable to the following program types: RF, TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment must be a 100% outside air, HTHV direct fired gas heater with a discharge temperature greater than or equal to 150°F, a temperature rise that is greater than or equal to 140°F, and an efficiency exceeding 92%.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment must be an indirect fired gas, steam unit heater, or a rooftop unit used as the primary space heating source. Warehouses with existing destratification technologies (high volume, low speed fans or air turnover units) do not qualify for this measure.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 15 years.[961]

DEEMED MEASURE COST

The measure cost should be based on a contractor's evaluation of the project scope and may vary significantly on a project-to-project basis. If unknown, for early replacement or retrofit projects, assume $14.50/MBtuh (material cost for an HTHV unit) or $26/MBtuh (sum of material and installation cost).[962]

The incremental measure cost, assuming a baseline of standard efficiency unit heaters, is $7.43/MBtuh (material cost).[963]

COINCIDENCE FACTOR

Assumed to be 0.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

HTHV units may increase the facility's electric energy consumption due to high pressure motors that supply air at higher velocity.

$$\Delta kWh = -(kWh/HDD) * HDD$$

Where:

kWh/HDD = increase in electric energy consumption due to HTHV fan motor

= 1.04[964]

HDD = heating degree days

Zone	City	HDD55[965]	ΔkWh
1	Rockford	4,272	(4,443)
2	Chicago	4,029	(4,190)
3	Springfield	3,406	(3,542)
4	Belleville	2,515	(2,616)
5	Marion	2,546	(2,648)

Although HTHV fan motors have a higher power draw, they also result in decreased heating equipment operating time, potentially offsetting some of the increase in electrical energy consumption. Therefore, if replacing heating equipment other than unit heaters, a custom evaluation may be necessary to determine if there is an increase in electrical energy consumption.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Since HTHV units operate during the winter (non-peak) season, there are no demand savings associated with this measure.

FOSSIL FUEL SAVINGS

Custom calculation below. Otherwise, use a deemed savings factor from the table that follows.

$$\Delta Therms = (FLH_{base} * Cap_{base} / (\eta_{base} * 100)) - (FLH_{eff} * Cap_{eff} / (\eta_{eff} * 100))$$

Where:

$FLH_{base} = LF_{base} * Hours$

$FLH_{eff} = LF_{eff} * Hours$

Hours = Annual operating hours of the unit, calculated as total number of hours when outside air temperature is less than 55°F. This can be adjusted based on the facility's occupancy schedule.

[964] Based on data collected in "Field Demonstration of High Efficiency Gas Heaters", prepared for Better Buildings Alliance, US. DOE, Jim Young, Navigant Consulting, 2014. This study replaced four standard unit heaters with HTHV units, and the electrical energy increased from 0.40 kWh/HDD to 1.44 kWh/HDD. Therefore, savings are assumed to be 1.04 kWh /HDD.

[965] 30-year normals from the National Climactic Data Center (NCDC), assuming base temperature 55.

LF_{base} = load factor of baseline unit heater

= $(Q_{inf,base} + Q_{w,base} + Q_{r,base})/(Cap_{base} * 100)$

LF_{eff} = load factor of HTHV heater

= $(Q_{inf,eff} + Q_{w,eff} + Q_{r,eff})/(Cap_{eff} * 100)$

Cap_{base} = existing heating unit input capacity (MBtuh)

= can be collected on site, or assumed to be the same as HTHV unit capacity, Cap_{eff}

Cap_{eff} = HTHV unit input capacity (MBtuh)

= can be collected on site or from specification sheets

η_{base} = efficiency of existing heating unit

= collected from equipment nameplate or assumed as70% for steam unit heaters, 80% for gas fired unit heaters, and 84% for rooftop units[966]

η_{eff} = efficiency of HTHV unit

= collected from equipment nameplate or assumed as 92%

100 = converts MBtu to therms

See following table for savings inputs.

[966] Efficiency of existing systems assumed from ASHRAE 90.1 – 2010 and manufacturer's specification sheets for various equipment. Steam unit heaters have a lower efficiency due to steam distribution losses.

Parameter	Existing Unit	Proposed (Efficient) Unit
Temperatures		
Setpoint Temperature (°F):	$T_{setpoint}$ = collected on site, or assumed as 65°F	
Ceiling Temperature[967] (°F):	Either collected on site when the existing unit is in operation with an infrared gun or assumed as: $T_{c,base}$= $T_{setpoint}$ + 0.53°F/ft * Height	Either collected on site when the proposed unit is in operation with an infrared gun or assumed as: $T_{c,eff}$ = $T_{setpoint}$ + 2 to 4°F
Average Room Temperature (°F):	$T_{r,base}$= ($T_{setpoint}$ + $T_{c,base}$) / 2	$T_{r,eff}$= ($T_{setpoint}$ + $T_{c,eff}$) / 2
Outside Air Temperature (°F):	T_{OA} from local weather data[968]	
Heat Loads		
Infiltration Load[969]:	$Q_{inf,base}$= 0.04CFM/ft^2 * (Wall Surface Area + Roof Surface Area) * 1.08 * ($T_{r,base}$ - T_{OA})	$Q_{inf,eff}$= 0.04CFM/ft^2 * (Wall Surface Area + Roof Surface Area) * 1.08 * ($T_{r,eff}$ - T_{OA})
Wall Conduction Load[970]:	$Q_{w,base}$ = 1/R-value$_{wall}$ * (Wall Surface Area * 1.08 * ($T_{r,base}$ - T_{OA}) Where: R-value$_{wall}$ = the insulation value of the wall. It can be collected on site or assumed as R-15.	$Q_{w,eff}$ = 1/R-value$_{wall}$ * (Wall Surface Area * 1.08 * ($T_{r,eff}$ - T_{OA}) Where: R-value$_{wall}$ = the insulation value of the wall. It can be collected on site or assumed as R-15.
Roof Conduction Load:	$Q_{r,base}$ = 1/R-value$_{roof}$ * (Roof Surface Area * 1.08 * ($T_{r,base}$ - T_{OA}) Where: R-value$_{roof}$ = the insulation value of the roof. It can be collected on site or assumed as R-20.	$Q_{r,eff}$ = 1/R-value$_{roof}$ * (Roof Surface Area * 1.08 * ($T_{r,eff}$ - T_{OA}) Where: R-value$_{roof}$ = the insulation value of the roof. It can be collected on site or assumed as R-20.
Surface Areas		
Roof Surface Area:	Collected on site or assumed as: = facility area in ft^2 If facility area is unknown, assume facility area[971]: = 41.4 ft^2/MBtuh * Cap$_{eff}$	
Wall Surface Area:	Collected on site or assumed as: = (Height * Length + Height * Width) * 2 Where: Length, height, and width (feet) of the facility can be collected on site. If unknown, assume: Length = Width = (Facility Area)$^{1/2}$ and Height = 25 ft If facility area is unknown, assume facility area: = 41.4 ft^2/MBtuh * Cap$_{eff}$	

The default values from the table above were used to calculate the deemed savings values in the following table. Savings are provided for various rated input capacity ranges and weather stations.

[967] Baseline stratification rate is based on data collected in "Field Demonstration of High Efficiency Gas Heaters", prepared for Better Buildings Alliance, US. DOE, Jim Young, Navigant Consulting, 2014. The study also verifies that the proposed ceiling temperature can be maintained within 2-4°F of the setpoint.
[968] Use Typical Meteorological Year (TMY3) data from NREL.
[969] Typical infiltration rate assumed from Infiltration Modeling Guidelines for Commercial Building Energy Analysis, prepared for US. DOE by Pacific Northwestern National Laboratory, 2009.
[970] Roof and Wall Insulation R-values are based on ASHRAE 90.1- 2010. (Jim Young 2014) (K. Gowri 2009).
[971] Based on DOE's Commercial Prototype Modeled Warehouse building (in Chicago), via the Building Energy Codes Program.

4.4.40 Gas High Efficiency Single Package Vertical Air Conditioner

DESCRIPTION

This measure covers the installation of a single package vertical air conditioner (SPVAC) with a high efficiency gas furnace, referred to here as a through-the-wall (TTW) condensing gas furnace instead of a standard efficiency gas furnace. The primary market served by TTWs are multifamily housing and hospitality in a new construction application. High efficiency gas furnaces achieve savings through the utilization of a sealed, super insulated combustion chamber, more efficient burners, and multiple heat exchangers that remove a significant portion of the waste heat from the flue gases. Because multiple heat exchangers are used to remove waste heat from the escaping flue gases, most of the flue gases condense and must be drained. Management of the acidic condensate is currently a major limiting factor for retrofit application, making the new construction the best initial market point until the industry develops better strategies for condensate management for retrofit applications. Also, TTWs are normally installed at the exterior wall to access outside air to reject heat in the cooling cycle. Placement of TTWs near the exterior might be prohibitive in retrofit applications. Furnaces equipped with ECM fan motors and with above code EER ratings provide an opportunity for additional electric energy savings.

This measure assumes a unit size less than or equal to 65,000 Btu/hr.

This measure was developed to be applicable to the following program types: NC, TOS. If applied to other program types such as RF, the measure savings should be verified via a custom measure.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a TTW condensing system with a code minimum 11.0 EER cooling system and a high-efficiency gas furnace with an annual fuel utilization efficiency (AFUE) of 90% or greater.[972] Fan electrical efficiency must exceed the program requirements.

DEFINITION OF BASELINE EQUIPMENT

Baseline equipment for this measure are units with a cooling system that meets the current code minimum 11.0EER efficiency rating and a heating unit with an AFUE rating of 80% or less.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 16.5 years.[973]

DEEMED MEASURE COST

The incremental capital cost for this measure depends on efficiency as listed below:[974]

AFUE	Incremental Cost Premium
80%	$400
90%	$400
95%	$500

LOADSHAPE

Loadshape R08 – Residential Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits. The second represents the average savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

[972] Electronic Code of Federal Regulations: 10 CFR 431.97, last modified on September 23, 2019.
[973] Average of 15-18 year lifetime estimate made by the Consortium for Energy Efficiency in 2010.
[974] Based on discussion with TTW Manufacturers at AHR 2018 Show in Chicago, IL.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[975]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[976]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Electric savings come from a high efficiency cooling unit.[977] In some instances, the TTW unit provided by the manufacturer may not have higher efficiency cooling and fan blower motor systems integrated into the TTW design; in these cases, electric energy savings will be zero for those components.

$$\Delta kWh_{EER} = FLH_{cool} * Capacity * (1/EER_{base} - 1/EER_{eff}) / 1000$$

Where:

FLH_{cool} = Full load hours for cooling:[978]

Climate Zone (City based upon)	FLH_{cool} (multifamily)
1 (Rockford)	499
2 (Chicago)	629
3 (Springfield)	707
4 (Belleville)	982
5 (Marion)	868
Weighted Average	655

Capacity = Cooling capacity of the efficient unit in Btu/hr

= Actual installed

EER_{eff} = Energy efficiency ratio of the efficient equipment

= Actual installed rating

EER_{base} = Energy efficiency ratio of the baseline equipment[979]

= 11.0

For example, for a Rockford non-weatherized multifamily unit conditioned by a SPVAC with a 2-ton (24,000 Btu/hr) cooling capacity, a rated EER of 11.0, and an ECM fan blower motor installed.

[975] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[976] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[977] If an ECM motor in the packaged system is present, savings should be claimed for this measure by referring to the Residential Furnace Blower Motor measure in the IL TRM.
[978] Consistent with multifamily assumptions from Residential Volume. Full load hours for Chicago, Moline, and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.
[979] Electronic Code of Federal Regulations: 10 CFR 431.97, last modified on September 23, 2019.

ΔkWh	= [499 * 24,000 * (1/11.0 – 1/13.0) / 1,000] = 167 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = CF * Capacity * (1/EER_{base} - 1/EER_{eff}) / 1{,}000$$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[980]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[981]

FOSSIL FUEL SAVINGS

$$\Delta Therms = EFLH_{heat} * Capacity * (AFUE_{eff} - AFUE_{base}) / AFUE_{base} / 100{,}000$$

Where:

$EFLH_{heat}$ = Equivalent Full Load Hours for heating:

Climate Zone (City based upon)	$EFLH_{heat}$ (general multifamily)
1 (Rockford)	1,924
2 (Chicago)	1,726
3 (Springfield)	1,708
4 (Belleville)	1,195
5 (Marion)	1,270

Capacity = Nominal heating input capacity furnace size (Btu/hr) for efficient unit

= Actual

$AFUE_{eff}$ = Efficient furnace annual fuel utilization efficiency rating

= Actual installed rating

$AFUE_{base}$ = Baseline furnace annual fuel utilization efficiency rating

= 80%

100,000 = Btu/Therm

[980] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[981] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[982] Consistent with multifamily assumptions from Residential Volume. Full load heating hours for heat pumps are provided for Rockford, Chicago and Springfield in the ENERGY STAR Calculator. Estimates for the other locations were calculated based on the FLH to Heating Degree Day (from NCDC) ratio. VEIC consider ENERGY STAR estimates to be high due to oversizing not being adequately addressed. Using average Illinois billing data (from ICC commerce Commission) VEIC estimated the average gas heating load and used this to estimate the average home heating output (using 83% average gas heat efficiency). Dividing this by a typical 36,000 Btu/hr ASHP gives an estimate of average ASHP FLH_heat of 1821 hours. We used the ratio of this value to the average of the locations using the ENERGY STAR data (1994 hours) to scale down the ENERGY STAR estimates. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

For example, for a Chicago non-weatherized multifamily unit heated by an SPVAC with a 40 kBtu/hr capacity and a rated AFUE of 93%.

ΔTherms = 1,726 * 40,000 * [(0.93 – 0.8) / 0.8] / 100,000
= 112 therms

4.4.41 Advanced Rooftop Controls (ARC)

DESCRIPTION

The Advanced Rooftop Controls (ARC) measure installs demand-controlled ventilation with optional supply-fan speed control via a variable-frequency drive or multi-speed motor to a single-zone, packaged HVAC unit with a functioning integrated economizer already installed. The demand-controlled ventilation modulates the outside air damper based on CO_2 concentration in the conditioned space. The supply-fan speed control options consist of setting the fan speed to 40% in ventilation mode and to 90% in heating and cooling modes, or of setting the fan speed to 40% in ventilation mode, to 75% in 1st stage heating and 1st stage cooling modes, and to 90% in 2nd stage heating and 2nd stage cooling modes. The measure results in fan, cooling, and heating savings compared to a baseline scenario of constant-volume, constant-ventilation operation typical of single-zone, packaged HVAC units. There are several off-the-shelf products available for the packaged HVAC unit market that support these control sequences, and the energy savings potential of these strategies has been studied and reported on.[983]

Demand-controlled ventilation modulates the percentage of outside air that is delivered to a space and its occupants by controlling the position of the outside air damper. The outside air damper is set to the minimum position required for the space and is opened further when CO_2 concentration in the conditioned space increases which indicates an increase in occupancy. The damper also opens to provide 100% outside air cooling (i.e., the unit economizes) when conditions permit. This portion of the measure saves energy by minimizing the energy required to unnecessarily heating and cooling outside air. Demand-controlled ventilation can also be combined with the installation of a variable-frequency drive or a multi-speed motor on the supply fan. This drive is used to reduce the speed of the supply fan when the full design airflow is not required. When the unit is only providing ventilation air (i.e., not heating or cooling), the airflow is reduced substantially but not below the required minimum ventilation rate. The flow for heating and cooling can also be reduced a small amount in most cases. Per the fan affinity laws, the reduction in flow correlates to a near cubic reduction in fan power. In these ways, this measure is able to achieve cooling, heating, and fan energy reduction.

This measure is intended for commercial buildings served by single-zone, packaged HVAC units. This measure was developed to be applicable to the following program types: RF, DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is a single-zone, packaged HVAC unit (with an existing functional integrated economizer) that has been retrofitted with demand-controlled ventilation controls with optional supply-fan speed control via a variable-frequency drive.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a single-zone, packaged HVAC unit (with an existing functional integrated economizer) that lacks demand-controlled ventilation controls and lacks supply-fan speed control via a variable-frequency drive.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The deemed measure life is 10 years and based on the estimated life of a CO_2 sensor.[984]

DEEMED MEASURE COST

Actual measure costs should be used if available. If costs are not available, the deemed measure cost below can be used.

---

[983] Katipamula, S., et al, "Advanced Rooftop Control (ARC) Retrofit: Field-Test Results", Pacific Northwest National Laboratory, July 2013.

[984] During conversations with vendors and Building Automation System (BAS) contractors, it was determined that sensors must be functional for up to 10 years. It is recommended that they are part of a normal preventive maintenance program in which calibration is an important part of extending useful life. Although they are not subject to mechanical failure, they do fall out of tolerance over time.

Table 1 – Deemed Measure Cost Details

Measure	Material Unit (Each)	Material Cost / Unit	Labor Unit (Hours)	Labor Rate/ Unit	Total Cost
DCV	1	$1,663.90	3	$96.67	$1,953.91
DCV and VFD or multi-speed motor with two speed modes (40% ventilating & 90% heating/cooling)	1	$3,025.38	4	$96.67	$3,412.06
DCV and VFD or multi-speed motor with three speed modes (40% ventilating, 75% 1st stage heating/ cooling, & 90% 2nd stage heating/cooling)	1	$3,487.00	4	$96.67	$3,873.68

Commercial ventilation C23

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [985]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [986]

Algorithm

CALCULATION OF ENERGY SAVINGS

To determine the savings associated with the Advanced Rooftop Controls (ARC) measure we utilized the available IL TRM prototype eQuest models which were initially created by the Energy Center of Wisconsin[987] but modified by VEIC in 2014 as part of the IL TRM v4.0 Equivalent Full Load Hours (EFLH) update. For each building type we used the most recent versions of the models for our baseline models (Assembly was not part of EFLH update). These models which were used are the most up-to-date versions and are readily available on the VEIC SharePoint site, under the TRM Reference Documents Section.

Upon examination of the ComEd building prototype models we found several of the baseline models did not have packaged single zone (PSZ) units. This measure is targeting packaged single zone HVAC systems. Therefore, as a basis for savings calculations, we chose only models that: 1) utilized PSZ HVAC systems, and 2) aligned with the small commercial building type applicable to this measure. Once the ComEd baseline models were selected, we determined several modifications were necessary to the prototype models in order to represent the baseline scenario for this measure:

1. Multistage PSZ HVAC System with Constant Volume Supply Fan
2. Optimized Economizer Controls by Climate Zone
    a. Economizer Changeover Type – Set to fixed Dry Bulb
    b. Economizer High-Limit Control Setpoints – Setpoints based on ASHRAE Climate Zones Fixed Dry Bulb Temperature recommendations.

[985] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[986] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[987] Energy Center of Wisconsin, ComEd Portfolio Modeling Report, July 30, 2010.

c. Enable Integrated Operation – Allows economizer to operate simultaneously with mechanical cooling

Additionally, several the building prototype models were found to have supply fan total static pressure modeled inputs that seem excessive and atypical for packaged single zone rooftop units – these included convenience stores (5 in. wc), manufacturing facilities (5 in. wc), office low rises (5 in. wc), religious buildings (5 in. wc), and restaurants (5 in. wc). The remaining models had supply fan total static pressure inputs more in line with what we would expect to find for packaged single zone rooftop units, ranging from 1.3 to 2 in. wc. For each model having a supply fan total static pressure above 2 in. wc, model inputs were adjusted to set these to 2 in. wc. To implement the modifications shown above, changes were made to eQUEST keywords in the ComEd prototype models as shown in the following table. Hard-coded system capacities and supply airflows can be found in the attached "Advanced Rooftop Controls_End Use Analysis_IL TRM.xlsx" spreadsheet.

Table 2 – Prototype Modifications to eQuest Keywords

Component Adjusted	eQuest Keyword	IL TR Value	Modified Prototype Value
System - System Type	SYSTEM:TYPE	PSZ	PVVT
System - Airflow and Temperature Control	SYSTEM:AIR/TEMP-CONTROL	N/A	STAGED-VOLUME
System – Supply Fan Total Static Pressure	SYSTEM:SUPPLY-STATIC	Varies	If >2: 2 Else: IL TR Value
System - Cooling and Heating Capacities	SYSTEM:COOLING-CAPACITY SYSTEM:HEATING-CAPACITY	Auto-sized	Hard-coded (after retrieving auto-sized outputs)
System - Supply Fan Control	SYSTEM:FAN-CONTROL	Varies	CONSTANT-VOLUME
System - Supply Fan Ratios	SYSTEM:MIN-FLOW-RATIO SYSTEM:CMIN-FLOW-RATIO SYSTEM:HMIN-FLOW-RATIO SYSTEM:-MAX-FAN-RATIO	N/A	1
System - Supply Airflow	SYSTEM:SUPPLY-FLOW	Auto-sized	Hard-coded (after retrieving auto-sized outputs)
Economizer - Changeover Type	SYSTEM:OA-CONTROL	Fixed	Single Dry-Bulb
Economizer - Changeover Setpoint	SYSTEM-ECONO-LIMIT-T	Varies	ASHRAE 90.1-2013 – High-Limit Shutoff Control Settings: ASHRAE CLIMATE ZONE – 4A = 65°F ASHRAE CLIMATE ZONE – 5A = 70°F
Economizer - Integrated Operation	SYSTEM:ECONO-LOCKOUT	Yes	No

Further modifications were then made to these baseline models to simulate the following measure scenarios:

1. Demand-controlled ventilation (DCV) controls
2. DCV and supply fan variable frequency drive (VFD) with two fan speed modes
    a. 40% fan speed for ventilating
    b. 90% fan speed for heating and cooling
3. DCV and supply fan VFD with three fan speed modes
    a. 40% fan speed for ventilating
    b. 75% fan speed for 1st stage heating and cooling

c. 90% fan speed for 2nd and higher stage heating and cooling

The eQuest modifications from the baseline models to represent these measure scenarios are shown in the following table. Full modeled energy end use and savings summaries can be found in the attached "Advanced Rooftop Controls_End Use Analysis_IL TRM.xlsx" spreadsheet.

Table 3 – Baseline and Measure Scenario eQuest Keywords

Component Adjusted	eQuest Keyword	Baseline Value	Measure Scenario Values		
			1	2	3
System - Minimum Outside Air Control	SYSTEM:MIN-OA-METHOD	Fraction of Design Flow	DCV Return Sensor	DCV Return Sensor	DCV Return Sensor
System - Supply Airflow	SYSTEM:SUPPLY-FLOW	Hard-coded	1.0 × Hard-coded value	0.9 × Hard-coded value	0.9 × Hard-coded value
System - Supply Fan Control	SYSTEM:FAN-CONTROL	CONSTANT-VOLUME	CONSTANT-VOLUME	FAN-EIR-FPLR	FAN-EIR-FPLR
System - Supply Fan Ratios	SYSTEM:MIN-FLOW-RATIO	1	1	0.44*	0.44*
	SYSTEM:CMIN-FLOW-RATIO	1	1	1	0.83**
	SYSTEM:HMIN-FLOW-RATIO	1	1	1	0.83**
	SYSTEM:-MAX-FAN-RATIO	1	1	1	1

*Since the total supply flow is limited by 0.9 of the baseline, a value of 0.44 for the minimum flow ratio results in a 40% fan speed: 0.4/0.9=0.44

** Since the total supply flow is limited by 0.9 of the baseline, a value of 0.83 for the minimum heating/cooling flow ratios results in a 75% fan speed: 0.75/0.9=0.83

With these modifications in place each scenario was simulated in eQuest for each chosen IL TRM prototype building type across the five TRM climate zones. Whole building electric and gas savings were determined from the simulation output and are presented in the following sections. Electric savings have been normalized by cooling tons and heating savings by furnace kBtuh output.

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (Capacity_{Cool} \times Normalized\ Electric\ Cooling\ Energy\ Savings) + (Capacity_{Heat} \times Normalized\ Electric\ Heating\ Energy\ Savings)$$

Where:

$Capacity_{Cool}$ = capacity of the cooling equipment in tons (nominal tonnage may be used).

= Actual

Normalized Electric Cooling Energy Savings

= kWh/ton savings value for the appropriate combination of building type, climate zone, and measure scenario per Table 4 – Electric Cooling Energy Savings Summary (kWh/ton)

Table 4 – Electric Cooling Energy Savings Summary (kWh/ton)

Retail - Strip Mall	286.3	226.6	202.8	250.5	190.8	178.9	214.7	167.0	155.1	202.8	167.0	155.1	178.9	143.1	131.2

For example, a 10-ton rooftop heat pump on an office low rise building in Chicago installs DCV with 2-speed supply fan control (operating at 40% in ventilating mode and 90% in heating and cooling modes):

ΔkWh = ($Capacity_{Cool}$ × Normalized Electric Cooling Energy Savings) + ($Capacity_{Heat}$ × Normalized Electric Heating Energy Savings)

= (10 tons × 1,065.8 kWh/ton) + (10 tons × 107.4 kWh/ton)

= 11,732 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW_{SSP} = (tons) \times Normalized\ Electric\ Cooling\ Peak\ Demand\ Savings \times CF_{SSP}$$

$$\Delta kW_{PJM} = (tons) \times Normalized\ Electric\ Cooling\ Peak\ Demand\ Savings \times CF_{PJM}$$

Where:

tons = capacity of the cooling equipment in tons (nominal tonnage may be used).

= Actual

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [989]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [990]

Normalized Electric Peak Demand Savings

= kW/ton savings value for the appropriate combination of building type, climate zone, and measure scenario per Table 6 – Electric Peak Demand Savings Summary (kW/ton)

Table 6 – Electric Peak Demand Savings Summary (kW/ton)

4.4.42 Advanced Thermostats for Small Commercial – Retired 12/31/2019. Replaced with 4.4.48 Small Commercial Thermostats

4.4.43 Packaged RTU Sealing

DESCRIPTION

The HVAC Packaged RTU Sealing Measure targets areas of the RTU that are readily accessible and can be easily sealed. By sealing the following areas, the amount of uncontrolled infiltration will be reduced leading to increased occupant comfort and an overall reduction in energy use.

The measure seeks to target the following three areas for sealing.

1. Economizer Hood – Seal the interior and exterior seams that connect the economizer to the RTU using UL listed metal tape and/or silicone caulking.
2. RTU Curb – Seal supply and return duct seams inside of RTU with mastic along with any leaks that are found around the perimeter of the roof to RTU connection using UL listed metal tape and/or silicone caulking.
3. Non-Removable Cabinet Panels – Seal all cabinet seams that are not typically removed during basic service (i.e., control panel) using UL listed metal tape and/or silicone caulking.

Uncontrolled infiltration of non-conditioned outside air (OSA) is a known issue for packaged rooftop units (RTU). This leakage can occur through the curb, economizer assembly connection and cabinet panels. This leakage not only influences occupant comfort but also increases energy usage by increasing the heating and cooling loads while also reducing the unit's operating energy efficiency.

Prior to a laboratory and field study developed by Robert Mowris & Associates, Inc.,[991] the energy effects of uncontrolled infiltration through cabinet leakage were difficult to quantify. However, this study determined that uncontrolled OSA infiltration not only increases the amount of energy to condition the excess air but also reduces the unit's operating efficiency (sensible EER) by 5.4%. By reducing the amount of uncontrolled OSA infiltration through RTU sealing the unit's operating efficiency (EER) can be increased reducing the amount of cooling energy. (Note: The referenced study quantifies improvements only from sealing the economizer hood – sealing the curb and non-access panels are recommended practice here but savings have not been quantified for these actions and may be in a future revision.)

This measure is only appropriate for packaged single zone rooftop units. Custom calculations are required for savings for built up air handling units or packaged multizone systems.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment condition is assumed to be a packaged HVAC system that has had the economizer hood, curb and non-access cabinet panels sealed.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment condition is assumed to be an operational packaged HVAC system that has not been previously sealed. The packaged HVAC systems must be single zone and must have a functioning economizer.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

Because the measure targets existing packaged RTU units, the deemed lifetime of the measure is assumed to be 5 years.[992]

[991] Robert Mowris & Associates, Inc., "Laboratory Test Results of Commercial Packaged HVAC Maintenance Faults," California Public Utilities Commission, Feb 15, 2016 page 203.

[992] Assumed to be one third of effective useful life of an RTU (15 years).

DEEMED MEASURE COST

Actual measure costs should be used if available. If costs are not available, the deemed measure cost listed below can be used. The deemed measure costs are detailed for each individual RTU[993].

Measure	Material Unit	Material Cost / Unit	Labor Unit (Hours)	Labor Rate / Unit	Total Cost
HVAC Packaged RTU Sealing	1	$49.69	1.5	$51.00	$126.19

LOADSHAPE

Loadshape C03 - Commercial Cooling

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [994]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [995]

Algorithm

CALCULATION OF ENERGY SAVINGS

To determine the savings associated with the Packaged RTU Sealing measure available IL TRM prototype eQuest models, which were initially created by the Energy Center of Wisconsin[996] but modified by VEIC in 2014 as part of the IL TRM v4.0 Equivalent Full Load Hours (EFLH) update, were utilized. For each building type we used the most recent versions of the models for our baseline models (Assembly was not part of EFLH update).

This measure is targeting packaged single zone HVAC systems. Therefore, as a basis for savings calculations, only models that had the following characteristics were chosen: 1) Packaged-Single Zone (PSZ) HVAC systems; and 2) aligned with the small commercial building type applicable to this measure. Several modifications to the models were necessary in order to simulate a functioning airside economizer, which is assumed to be present in the baseline scenario for this measure:

3) Optimized Economizer Controls by Climate Zone
   a. Economizer Changeover Type – Set to fixed Dry Bulb
   b. Economizer High-Limit Control Setpoints – Setpoints based on ASHRAE Climate Zones Fixed Dry Bulb Temperature recommendations.
   c. Enable Integrated Operation – Allows economizer to operate simultaneously with mechanical cooling

To determine the energy use associated with an unsealed RTU, the prototype models were modified using the associated reduction in efficiency reported in a Robert Mowris and Associates, Inc. study that was performed for the California Public Utilities Commission in 2016.[997] For further detail on the full modeled energy end use and savings summaries, see: "Packaged RTU Sealing_End Use Analysis_IL TRM 09042018.xlsx" spreadsheet.

[993] Web retailer costs for sealing materials and RS Means open-shop labor cost for Chicago, IL for the year 2025. See reference document "Packaged RTU Sealing_End Use Analysis_IL TRM 05152025.xlsx"
[994] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[995] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[996] Energy Center of Wisconsin, ComEd Portfolio Modeling Report, July 30, 2010.
[997] Robert Mowris & Associates, Inc., "Laboratory Test Results of Commercial Packaged HVAC Maintenance Faults," California Public Utilities Commission, Feb 15, 2016 Section 5.4.

After analyzing the modeled cooling annual energy usage for both the baseline (unsealed) and measure (sealed) model scenarios it was determined that the building type and climate zone variables had a minimal impact on the overall energy savings associated with the measure. As a result, the overall average savings factor of 4.67% was deemed applicable for any small commercial building type across all climate zones. This single savings value used in conjunction with the energy and demand savings calculations listed in the following sections will allow the savings to be calculated based on the unit size and equivalent full load hours listed in the Illinois Technical Resource Manual (TRM).

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (kBtu/hr) \,/\, EER_{before} * EFLH_{cooling} * \%Savings$$

Where:

kBtu/hr = rated capacity of the cooling equipment actually installed in kBtu per hour (1 ton of cooling capacity equals 12 kBtu/hr).

= Actual

EER_{before} = Energy Efficiency Ratio (EER) of the baseline equipment * distribution efficiency

=Actual (assume 95% distribution efficiency)

%Savings = Deemed savings percentage

= 4.67%[998]

$EFLH_{cooling}$ = Equivalent Full Load Hours for cooling in Existing Buildings from section 4.4 HVAC End Use

For example, a 12 EER 5-ton rooftop air conditioner on a department store in Rockford receives packaged RTU sealing:

$$\Delta kWh = (5 * 12) \,/\, 12 * 639 * 4.67\%$$
$$= 149.2\ kWh$$

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kWssp = (kBtu/hr) \,/\, EER_{before} * \%Savings * CF_{SSP}$$

$$\Delta kWpjm = (kBtu/hr) \,/\, EER_{before} * \%Savings * CF_{PJM}$$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [999]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

[998] The average cooling energy savings for all building types and climate zones, as determined by modeling 13 small commercial building types across 5 weather zones utilizing the prototype TRM eQuest models. For additional reference on the methodology and approach to the calculation of the deemed savings factor, see "Packaged RTU Sealing_End Use Analysis_IL TRM 2022.xlsx".

[999] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

= 47.8% [1000]

Other variables as provided above

For example, a 12 EER 5-ton rooftop air conditioner using the Summer System Peak Coincidence Factor receives RTU sealing:

ΔkW = $(5 * 12) / 12 * 4.67\% * 91.3\%$

= $0.213\ kW$

FOSSIL FUEL SAVINGS

ΔTherm = $(kBtu/hr) / 100 / Efficiency_{before} * EFLH_{heating} * \%Savings$

Where:

kBtu/hr = rated capacity of the heating equipment actually installed in kBtu per hour

= Actual

100 = Converts kBtu/hr to Therms/hr

$Efficiency_{before}$ = Efficiency of the baseline equipment (rated) * distribution efficiency

= Actual (assuming 95% distribution efficiency)

%Savings = Deemed savings percentages by building type and climate zone are provided in the following table

Building Type	Savings Percentage				
	Zone 1 (Rockford)	Zone 2 (Chicago)	Zone 3 (Springfield)	Zone 4 (Belleville)	Zone 5 (Marion)
Assembly	2.84%	2.86%	2.86%	2.98%	2.94%
Assisted Living	4.01%	4.15%	4.35%	4.64%	5.44%
College	3.86%	3.88%	3.97%	4.09%	5.10%
Conditioned Storage (Warehouse)	0.92%	0.90%	0.87%	1.00%	1.23%
Convenience Store	3.07%	3.20%	3.43%	3.70%	4.63%
Garage	0.20%	0.21%	0.22%	0.23%	0.29%
Grocery	3.38%	3.49%	3.60%	3.79%	4.57%
Manufacturing Facility	0.18%	0.16%	0.16%	0.16%	0.16%
Office - Low Rise	2.19%	2.23%	2.37%	2.46%	2.96%
Religious Building	0.28%	0.28%	0.30%	0.31%	0.37%
Restaurant	2.76%	2.83%	2.96%	3.11%	3.58%
Retail - Department Store	1.87%	1.91%	2.00%	2.14%	2.88%
Retail - Strip Mall	2.06%	2.12%	2.29%	2.46%	3.17%

$EFLH_{heating}$ = Equivalent Full Load Hours for heating in Existing Buildings from section 4.4 HVAC End Use

[1000]Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

For example, a packaged RTU with an 80% efficient 150-kBtu/hr gas furnace on a department store in Rockford receives packaged RTU sealing:

$$\Delta\text{Therm} = (150 / 100) / 80\% * 1{,}365 * 1.87\%$$
$$= 47.9\ Therms$$

REVIEW DEADLINE: 1/1/2029

4.4.44 Commercial Ground Source and Ground Water Source Heat Pump

DESCRIPTION

This measure characterizes the installation of a Ground Source Heat Pump under the following scenarios:

A. New Construction:
   i. The installation of a new Ground Source Heat Pump system meeting ENERGY STAR[1001] efficiency standards presented below in a new C&I building.
   ii. Note the baseline in this case should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition.

B. Time of Sale:
   i. The planned installation of a new Ground Source Heat Pump system meeting ENERGY STAR efficiency standards presented below to replace an existing system(s) that does not meet the criteria for early replacement described in section C below.
   ii. Note the baseline in this case is an equivalent replacement system to that which exists currently in the building. Where unknown, the baseline should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition. The calculation of savings is dependent on whether an incentive for the installation has been provided by both a gas and electric utility, only an electric utility or only a gas utility.
   iii. DHW savings are calculated based upon the fuel type and efficiency of the existing unit.

C. Early Replacement/Retrofit:
   i. The early removal of functioning electric or gas space heating and/or cooling systems from service, prior to the natural end of life, and replacement with a new high efficiency Ground Source Heat Pump system.
   ii. Note the baseline in this case is the existing equipment being replaced. The calculation of savings is dependent on whether an incentive for the installation has been provided by both a gas and electric utility, only an electric utility or only a gas utility. DHW savings are calculated based upon the fuel and efficiency of the existing unit.
   iii. Early Replacement determination will be based on meeting the following conditions:
      - The existing unit is operational when replaced, or
      - The existing unit requires minor repairs to be operational, defined as costing less than:[1002]

Existing System	Maximum repair cost
Air Source Heat Pump	$263/ton
Chiller	$308/ton
Boiler (Steam)	$3.87/kBtu
Boiler (Hot Water)	$4.25/kBtu
Furnace	$2.49/kBtu
Ground Source Heat Pump	$2,185/ton

      - All other conditions will be considered Time of Sale.

   The Baseline efficiency of the existing unit replaced:
      - Use actual existing efficiency whenever possible.
      - If the efficiency of the existing unit is unknown, use assumptions based on the federal minimum standards provided in tables below.
      - If the operational status or repair cost of the existing unit is unknown use time of sale

[1001] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[1002] The Technical Advisory Committee agreed that if the cost of repair is less than 20% of the new baseline replacement cost (defined in the Measure Costs section), it can be considered early replacement.

assumptions.

The installation of the GSHP should meet the following design parameters to ensure a properly sized circulation pump. If the GSHP design does not meet the following parameters, a custom calculation should be performed to account for the motor energy consumed by the circulation pump. Optimal design parameters are:

- Circulation pump is included in the manufacturer assembly of the GSHP system
  Or;
- Circulation pump flow rate less than or equal to 3.0 GPM per system ton
- Variable flow controls on pumps serving systems greater than 10 tons. Variable flow controls include one of the following:
  - A variable speed system pump controlled from differential pressure and 2-way water flow control valves on each heat pump.
  - Individual on/off pumps on each heat pump controlled by heat pump demand. The heat pumps may be decoupled from the ground heat exchanger using a separate variable speed pump controlled by differential temperature across the ground loop.
- On/off or variable flow controls on pumps for systems less than 10 tons. On/off pump controls shall operate only when heat pump(s) are running.
- System pumping head less than 80 feet. For systems 10 tons or smaller system pumping head should not exceed 40 feet.

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

For these products, the baseline equipment includes Air Conditioning, Space Heating and Domestic Hot Water Heating.

New Construction:

To calculate savings with an electric baseline, the baseline equipment is assumed to be an Air Source Heat Pump meeting the Federal Standard efficiency level as outlined in Table 2 (effective 1/1/2016 to 6/30/2019) or Table 7 (effective 7/1/2019 to 9/30/2022) or Table 12 (effective 10/1/2022) ; and a Federal Standard electric hot water heater efficiency level as outlined in Table 6 (effective 1/1/2016 to 6/30/2019) or Table 11 (effective 7/1/2019 to 9/30/2022) or Table 16 (effective 10/1/2022).

To calculate savings with a chiller/unitary cooling systems and boiler/furnace baseline, the baseline equipment is assumed to meet the minimum standard efficiencies as outlined in the Table 3 (effective 1/1/2016 to 6/30/2019) or Table 8 (effective 7/1/2019 to 9/30/2022) or Table 13 (effective 10/12022)

Tablefor chillers/unitary cooling systems, and Table 4 (effective 1/1/2016 to 6/30/2019) or Table 9 (effective 7/1/2019 to 9/30/2022) or Table 14 (effective 10/1/2022) for boilers or Table 5 (effective 1/1/2016 to 6/30/2019) or Table 10 (effective 7/1/2019 to 9/30/2022) or Table 15 (effective 10/1/2022) for furnaces. If a desuperheater is installed, the domestic hot water heater minimum standard efficiency is calculated as per Table 6 (effective 1/1/2016 to 6/30/2019) or Table 11 (effective 7/1/2019 to 9/30/2022) or Table 16 (effective 10/1/2022) below.

In order for this characterization to apply, the baseline equipment is assumed to meet the efficiency requirements within the IECC code in effect on the date of the building permit. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Note, IECC 2021 became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code. If evaluation determines the applicable version of code, given location and timing, isn't an appropriate baseline due to supply constraints, low compliance, or other issues, the previous iteration of code may be used through 2023.

IECC 2021 leverages new DOE testing methods and associated metrics. The following conversion factors are recommended for use if the efficient equipment is not rated under the new testing procedure but the stipulated baseline is:[1003]

SEER2 = X * SEER

EER2 = X * EER

HSPF2 = X * HSPF

Where:

X	SEER2	EER2	HSPF2
Ducted	0.95	0.95	0.85
Ductless	1.00	1.00	0.90
Packaged	0.95	0.95	0.84

[1003] Consortium for Energy Efficiency (CEE), Testing, Testing, M1, 2, 3, Transitioning to New Federal Minimum Standards, CEE Summer Program Meeting, June 10, 2022.

Table 2: IECC 2015 ASHP Minimum Efficiency Requirements (effective 1/1/2016 to 6/30/2019)**:**

Air cooled absorption, single effect	All capacities	COP (W/W)	≥ 0.600 FL	NA[d]	AHRI 560
Water cooled absorption, single effect	All capacities	COP (W/W)	≥ 0.700 FL	NA[d]	AHRI 560
Absorption double effect, indirect fired	All capacities	COP (W/W)	≥ 1.000 FL	NA[d]	AHRI 560
			≥ 0.150 IPLV.IP		
Absorption double effect, direct fired	All capacities	COP (W/W)	≥ 1.000 FL	NA[d]	AHRI 560
			≥ 1.000 IPLV		

a. Chapter 6 contains a complete specification of the referenced standards, which include test procedures, including the reference year version of the test procedure.
b. The requirements for centrifugal chillers shall be adjusted for nonstandard rating conditions per Section C403.3.2.1 and are applicable only for the range of conditions listed there. The requirements for air-cooled, water-cooled positive displacement and absorption chillers are at standard rating conditions defined in the reference test procedure.
c. Both the full-load and IPLV.IP requirements must be met or exceeded to comply with this standard. When there is a Path B, compliance can be with either Path A or Path B for any application.
d. NA means the requirements are not applicable for Path B, and only Path A can be used for compliance.
e. FL is the full-load performance requirements, and IPLV.IP is for the part-load performance requirements.
f. This table is a replica of ASHRAE 90.1 Table 6.8.1-3 Water-Chilling Packages—Minimum Efficiency Requirements.

Table 14: IECC 2021 Boiler minimum efficiency requirements (expected to become effective statewide in 2023)

Note Code of Federal Regulations for gas -fired hot water boilers manufactured after January 15, 2021 require <300,000 Btuh hot water boilers to be 84% AFUE and <300,000 Btuh steam boilers to be 82% AFUE (10 CFR 432(e)(3)). This should be assumed baseline from 1/1/2022.

	≥ 200,000 Btu/h	≥ 4,000 Btu/h/gal and ≥ 10 gal	80% E_t $(Q/800 + 110\sqrt{V})SL$, Btu/h	
Storage water heaters, oil	≤ 105,000 Btu/h	≥ 20 gal and ≤ 50 gallons	0.68 – 0.0019V, EF	DOE 10 CFR Part 430
	≥ 105,000 Btu/h	< 4,000 Btu/h/gal	80% E_t $(Q/800 + 110\sqrt{V})SL$, Btu/h	ANSI Z21.10.3
Instantaneous water heaters, oil	≤ 210,000 Btu/h	≥ 4,000 Btu/h/gal and < 2 gal	0.59 – 0.0019V, EF	DOE 10 CFR Part 430
	> 210,000 Btu/h	≥ 4,000 Btu/h/gal and < 10 gal	80% E_t	ANSI Z21.10.3
	> 210,000 Btu/h	≥ 4,000 Btu/h/gal and ≥ 10 gal	78% E_t $(Q/800 + 110\sqrt{V})SL$, Btu/h	
Hot water supply boilers, gas and oil	≥ 300,000 Btu/h and < 12,500,000 Btu/h	≥ 4,000 Btu/h/gal and < 10 gal	80% E_t	ANSI Z21.10.3
Hot water supply boilers, gas	≥ 300,000 Btu/h and < 12,500,000 Btu/h	≥ 4,000 Btu/h/gal and ≥ 10 gal	80% E_t $(Q/800 + 110\sqrt{V})SL$, Btu/h	
Hot water supply boilers, oil	> 300,000 Btu/h and < 12,500,000 Btu/h	> 4,000 Btu/h/gal and > 10 gal	78% E_t $(Q/800 + 110\sqrt{V})SL$, Btu/h	

Time of Sale: The baseline for this measure is a new replacement unit of the same system type as the existing unit, meeting the minimum standard efficiencies provided above.

Early replacement / Retrofit: The baseline for this measure is the efficiency of the *existing* heating, cooling and hot water equipment for the assumed remaining useful life of the existing unit, and a new baseline heating and cooling system for the remainder of the measure life (as provided in table above).

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life of the ground source heat pump is assumed to be 25 years.[1004]

The expected measure life of the ground loop field is assumed to be 50 years.[1005]

For early replacement, the remaining life of existing equipment is assumed to be 6 years for ASHP and Central AC, 7 years for furnace, 8 years for boilers, chillers and GSHP,[1006] and 25 years for electric resistance.[1007]

DEEMED MEASURE COST

New Construction and Time of Sale: Incremental costs of the Ground Source Heat Pump should be used. This would be the actual installed cost of the Ground Source Heat Pump, well drilling, building retrofit, and system commissioning costs (default of $10,923/ton),[1008] minus the assumed installation cost of the baseline equipment (See table below for ASHP,[1009] or $12.43/kBtu capacity for a new baseline efficient furnace or $19.33/kBtu capacity for a new efficient steam boiler or $21.27/kBtu capacity for a new efficient hot water boiler,[1010] and $1,539/ton for new baseline chiller replacement[1011]).

Equipment Type	Capacity Range	Incremental Cost per Ton
Centrally Ducted Air Source Heat Pumps	< 2 tons	$88
	≥ 2 to < 3 tons	$70
	≥ 3 to < 4 tons	$59
	≥ 4 tons	$57

Early Replacement: The actual installed cost of the Ground Source Heat Pump should be used (default cost for total system retrofit provided above). The assumed deferred cost (after the appropriate number of years described above in the 'Deemed Lifetime of Efficient Equipment' section) of replacing existing equipment with a new baseline unit is presented in the table below for a new baseline Air Source Heat Pump, or is assumed to be $14.55/kBtu capacity for a new baseline efficient furnace or $23.15/kBtu capacity for a new efficient steam boiler or $25.47/kBtu capacity for a new efficient hot water boiler and $1,843/ton for new baseline chiller replacement[1012]. This future cost should be discounted to present value using the nominal societal discount rate.

[1004] System life of indoor components as per US DOE estimates from the Office of Energy Efficiency & Renewable Energy. The ground loop has a much longer life, but the compressor and other mechanical components are the same as an ASHP.
[1005] U.S. DOE Office of Energy Efficiency & Renewable Energy, Energy Saver details and descriptions for Geothermal Heat Pumps
[1006] Assumed to be one third of effective useful life of replaced equipment.
[1007] Assume full measure life (16 years) for replacing electric resistance as we would not expect that resistance heat would fail during the lifetime of the efficient measure.
[1008] Average calculated based on reviewing cost information received from Chicagoland GSHP installers.
[1009] In 2025, a working group was created to update costs for residential HVAC equipment. Heat Pump and Central Air Conditioning costs are based upon Ameren program data. Furnace and Boiler costs are based on Ameren, Nicor, People's Gas, and North Shore Gas program data. Baseline costs have been determined using ratios from Updated Buildings Sector Appliance and Equipment Costs and Efficiencies by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration. See file "HVAC Costs – 071825_VEIC.xlsx" for more details.
[1010] Average calculated based on RSMeans Mechanical Cost Data 2015.
[1011] Average calculated based on RSMeans Mechanical Cost Data 2015 for Scroll, air cooled condenser chillers.
[1012] All baseline replacement costs are consistent with their respective measures and include inflation rate of 2.28%.

Equipment Type	Capacity Range	Deferred Baseline Cost per Ton[1013]
Centrally Ducted Air Source Heat Pumps	< 2 tons	$5,268
	≥ 2 to < 3 tons	$4,226
	≥ 3 to < 4 tons	$3,541
	≥ 4 tons	$3,425

LOADSHAPE

Loadshape C04 – Commercial Electric Heating (if replacing building with no existing cooling)

Loadshape C05 - Commercial Electric Heating and Cooling

Note for the purpose of cost effectiveness screening for a fuel switch scenario, the heating kWh increase and cooling kWh decrease should be calculated separately such that the appropriate loadshape (i.e., Loadshape C04 - Commercial Electric Heating and Loadshape C03 – Commercial Cooling respectively) can be applied.

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1014]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1015]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS AND FOSSIL FUEL SAVINGS

Non-fuel switch measures:

$$\Delta kWh = [Cooling\ savings] + [Heating\ savings] + [DHW\ savings]$$

$$\text{Cooling Savings} = (Capacity_{cool} * EFLH_{Cool} * (1/EER2_{base} - 1/EER2_{GSHP}))/1000$$

$$\text{Heating Savings} = (Capacity_{Heat} * EFLH_{Heat} * (1/HSPF2_{base} - 1/(COP_{GSHP} * 3.412)))/1000$$

$$\text{DHW Savings} = Elec_{DHW} * (\%DHW * ((1/EF_{elecbase}) * HotWaterUse_{Gallon} * \gamma Water * (Tout - Tin) * 1/3412))$$

[1013] In 2025, a working group was created to update costs for residential HVAC equipment. Heat Pump and Central Air Conditioning costs are based upon Ameren program data. Furnace and Boiler costs are based on Ameren, Nicor, People's Gas, and North Shore Gas program data. Baseline costs have been determined using ratios from Updated Buildings Sector Appliance and Equipment Costs and Efficiencies by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration. See file "HVAC Costs – 071825_VEIC.xlsx" for more details.

[1014] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1015] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Fuel switch measures:

Fuel switch measures must produce positive total lifecycle energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows (note for early replacement measures the lifetime savings should be calculated by calculating savings for the remaining useful life of the existing equipment and for the remaining measure life):

SiteEnergySavings (MMBTUs) = $FuelSwitchSavings + NonFuelSwitchSavings$

FuelSwitchSavings = $GasHeatReplaced - GSHPSiteHeatConsumed$

NonFuelSwitchSavings = $FurnaceFanSavings + GSHPSiteCoolingImpact + GSHPSiteWaterImpact$

GasHeatReplaced = $(HeatLoad * 1/AFUE_{base})$ / 1,000,000

FurnaceFanSavings =$(FurnaceFlag * HeatLoad * 1/AFUE_{base} * F_e)$ / 1,000,000

GSHPSiteHeatConsumed = $(HeatLoad * 1/COP_{GSHP})$/ 1,000,000

GSHPSiteCoolingImpact = $(EFLH_{cool} * Capacity_{Cool} * (1/EER2_{base} - 1/EER2_{GSHP})/1000 * 3412)$/ 1,000,000

GSHPSiteWaterImpact$_{Gas}$ = $(\%DHWDisplaced * ((1/EF_{Gas} * GPD * Household * 365.25 * \gamma Water * (T_{OUT} - T_{in}) * 1.0)$ / 1,000,000

GSHPSiteWaterImpact$_{Electric}$ = $(\%DHWDisplaced * ((1/EF_{Elec} * GPD * Household * 365.25 * \gamma Water * (T_{OUT} - T_{in}) * 1.0)$/ 1,000,000

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Note for Early Replacement measures, the efficiency terms of the existing unit should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 6 years for furnace, 8 years for boilers or GSHP, 15 years for electric resistance), and the efficiency terms for a new baseline unit should be used for the remaining years of the measure. See assumptions below.

Where:

$Capacity_{cool}$ = Cooling Output Capacity of Ground Source Heat Pump (Btu/hr)
= Actual installed

$EFLH_{cool}$ = Cooling Equivalent Full Load Hours
Dependent on building type and Existing Buildings or New Construction, provided in section 4.4 HVAC End Use

$EER2_{Base}$ = Energy Efficiency Ratio (EER2) of existing cooling unit (kBtu/hr / kW).
For early replacement, use actual EER2 rating for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 8 years for GSHP). If EER2 unknown but SEER2 available, convert using the equation:[1016] $EER2_{exist} = (-0.02 * SEER2_{exist}^2) + (1.12 * SEER2_{exist})$.

For TOS, NC, and the remaining measure life of early replacement, use minimum standard efficiencies as specified in tables in 'Definition of Baseline Equipment' section.

$EER2_{GSHP}$ = Part Load Energy Efficiency Ratio efficiency of efficient GSHP unit[1017]
= Actual installed

HeatLoad = Calculated heat load for the building

$= EFLH_{Heat} * Capacity_{Heat}$

$Capacity_{Heat}$ = Heating Output Capacity of Ground Source Heat Pump (Btu/hr)
= Actual installed

$EFLH_{Heat}$ = Heating Equivalent Full Load Hours of heat pump
Dependent on building type and Existing Buildings or New Construction, provided in section 4.4 HVAC End Use

$HSPF2_{Base}$ = Heating System Performance Factor of baseline electric heating system (kBtu/kWh)
For early replacement, use actual HSPF2 rating for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 8 years for GSHP or 15 years for electric resistance). For electric resistance, assume 3.41.[1018].

For TOS, NC, and the remaining measure life of early replacement, use minimum standard efficiencies as specified in tables in 'Definition of Baseline Equipment' section.

COP_{GSHP} = Part Load Coefficient of Performance of efficient GSHP[1019]

= Actual installed

3.412 = Constant to convert the COP of the unit to the Heating Season Performance Factor (HSPF2)

$Elec_{DHW}$ = 1 if building has electric DHW
= 0 if building has non electric DHW
= 0 if one to one replacement of existing Ground Source Heat Pump

%DHW = Percentage of total DHW load that the GSHP will provide
= Actual if known
= If unknown and if desuperheater installed, assume 44%[1020]
= 0% if no desuperheater installed

$EF_{elecbase}$ = Energy Factor of baseline electric DHW
= Actual. If unknown or for new construction, assume federal standard as defined in applicable table in 'Definition of Baseline Equipment' section.

[1016] From Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder.
[1017] From Res GSHP measure of the IL-TRM: As per conversations with David Buss territory manager for Connor Co, the EER rating of an ASHP equate most appropriately with the full load EER of a GSHP.
[1018] Electric resistance has a COP of 1.0 which equals 1/0.293 = 3.41 HSPF.
[1019] As per Res GSHP measure.
[1020] Assumes that the desuperheater can provide two thirds of hot water needs for eight months of the year (2/3 * 2/3 = 44%). Based on input from Doug Dougherty, Geothermal Exchange Organization.

$HotWaterUse_{Gallon}$ = Estimated annual hot water consumption (gallons)

= Actual if possible to provide reasonable custom estimate. If not, two methodologies are provided to develop an estimate:

1. Consumption per usable storage tank capacity
   = Capacity * Consumption/cap

Where:

Capacity = Usable capacity of hot water storage tank in gallons

= Actual

Consumption/cap = Estimate of consumption per gallon of usable tank capacity, based on building type:[1021]

Building Type[1022]	Consumption/Cap
Convenience	528
Education	568
Grocery	528
Health	788
Large Office	511
Large Retail	528
Lodging	715
Other Commercial	341
Restaurant	622
Small Office	511
Small Retail	528
Warehouse	341
Nursing	672
Multi-Family	894

2. Consumption per unit area by building type
   = (Area/1000) * Consumption/1,000 sq.ft.

Where:

Area = Area in sq.ft that is served by DHW boiler

= Actual

Consumption/1,000 sq.ft. = Estimate of DHW consumption per 1,000 sq.ft. based on building type:[1023]

[1021] Methodology based on Cadmus analysis. Annual hot water usage in gallons based on CBECS (2012) and RECS (2009) consumption data of East North Central (removed outliers of 1,000 kBtuh or less) to calculate hot water usage. Annual hot water gallons per tank size gallons based on the tank sizing methodology found in ASHRAE 2011 HVAC Applications. Chapter 50 Service Water Heating. Demand assumptions (gallons per day) for each building type based on ASHRAE Chapter 50 and to LBNL White Paper. LBL-37398 Technology Data Characterizing Water Heating in Commercial Buildings: Application to End Use Forecasting. Assumes hot water heater efficiency of 80%.

[1022] According to CBECS 2012 "Lodging" buildings include Dormitories, Hotels, Motel or Inns and other Lodging and "Nursing" buildings include Assisted Living and Nursing Homes.

[1023] Methodology based on Cadmus analysis. Multi-Family	15,434

γWater = Density of water

= 8.33 pounds per gallon

T_{out} = Tank temperature

= 125°F

T_{in} = Incoming water temperature from well or municiplal system

= 50.7°F [1025]

1 = Heat Capacity of water (1 Btu/lb·°F)

3.412 = Conversion from Btu to kWh

$AFUE_{base}$ = Baseline Annual Fuel Utilization Efficiency Rating.
For early replacement measures, use actual AFUE rating for the remaining useful life of the existing equipment (6 years for furnace, 8 years for boilers).

For TOS, NC, and the remaining measure life of early replacement, use minimum standard efficiencies as specified in tables in 'Definition of Baseline Equipment' section.

FurnaceFlag = 1 if system replaced is a gas furnace, 0 if not.

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 7.7%[1026]

$EF_{GasBase}$ = Energy factor of Baseline natural gas DHW heater

= Actual. If unknown or New Construction, assume federal standard as defined in applicable table in 'Definition of Baseline Equipment' section.

3412 = Btu per kWh

[1024] According to CBECS 2012 "Lodging" buildings include Dormitories, Hotels, Motel or Inns and other Lodging and "Nursing" buildings include Assisted Living and Nursing Homes.

[1025] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[1026] F_e is estimated using TRM models for the three most popular building types for programmable thermostats: low-rise office (10.2%), sit-down restaurant (8.6%), and retail – strip mall (4.4%). 7.7% reflects the average Fe of the three building types. See "Fan Energy Factor Example Calculation 2021-06-23.xlsx" for reference.

%IncentiveElectric = % of total incentive paid by electric utility

= Actual

%IncentiveGas = % of total incentive paid by gas utility

= Actual

Non-Fuel Switch Illustrative Examples

New Construction using ASHP baseline:

For example, a 10 ton closed loop unit with Part Load EER rating of 20 and Part Load COP of 4.4, with desuperheater installed, and with a 100 gallon electric water heater in an new High School building in Chicago:

ΔkWh = [120,000 * 1,642 * (1/11 – 1/20) / 1000] + [1,549 * 120,000 * (1/11 – 1/(4.4*3.412)) / 1000] + [1 * 0.44 * ((1/0.9568 * (100*672) * 8.33 * (125-50.7) * 1)/3412)]

=8,061 + 4,516 +5,606 = 18,183 kWh

Early Replacement:

For example, a 10 ton closed loop unit with Part Load EER rating of 20 and Part Load COP of 4.4 and with desuperheater installed in in an Assisted living building in Chicago with a 100 gallon electric water heater, replacing an existing working Air Source Heat Pump with efficiency ratings of 8.2 EER and 7.7 HSPF:

ΔkWH for remaining life of existing unit (1st 8 years):

= [120,000 * 1,457 * (1/8.2 – 1/20) / 1000] + [1,646 * 120,000 * (1/7.7 – 1/(4.4*3.412)) / 1000] + [1 * 0.44 * ((1/0.9568 * (100*672) * 8.33 * (125-50.7) * 1)/3412)]

= 12,580 + 12,495 +5606 = 30,681 kWh

ΔkWH for remaining measure life (next 17 years):

= [120,000 * 1,457 * (1/11 – 1/20) / 1000] + [1,646 * 120,000 * (1/11 – 1/(4.4*3.412)) / 1000] + [1 * 0.44 * ((1/0.9568 * (100*672) * 8.33 * (125-50.7) * 1)/3412)]

= 7,153 + 4,800 +5,606 = 17,559 kWh

Fuel Switch Illustrative Example

[for illustrative purposes a 50:50 Incentive is used for joint programs]

Early Replacement fuel switch:

A 10 ton closed loop unit with Part Load EER rating of 20 and Part Load COP of 4.4 in an Assisted Living building in Chicago with a 100 gallon gas water heater replaces an existing working natural gas boiler with 75% efficiency and central AC of 9.5 EER, and desuperheater installed with natural gas existing DHW heater:

LifetimeSiteEnergySavings (MMBTUs) = $LifetimeGasHeatReplaced + LifetimeFurnaceFanSavings - LifetimeGSHPSiteHeatConsumed + LifetimeGSHPSiteCoolingImpact + LifetimeGSHPSiteWaterImpact$

LifetimeGasHeatReplaced =$((HeatLoad * 1/AFUE_{exist}) / 1{,}000{,}000 * 8\ years) + ((HeatLoad * 1/AFUE_{base}) / 1{,}000{,}000 * 17\ years)$

=$((120{,}000 * 1{,}646 * 1/0.75) / 1{,}000{,}000 * 8) + ((120{,}000 * 1{,}646 * 1/0.8) / 1{,}000{,}000 * 17)$

= $6304.2\ MMBtu$

= 0 MMBtu

GSHPSiteHeatConsumed = $(HeatLoad * 1/COP_{GSHP})$ / 1,000,000

= $(120{,}000 * 1{,}646 * 1/4.4)$/ 1,000,000

= $44.9\ MMBtu$

GSHPSiteCoolingImpact = ((EFLH$_{cool}$ * Capacity$_{Cool}$ * (1/EER$_{exist}$– 1/EER$_{GSHP}$))/1000 * 3412)/1,000,000

= $((120000 * 1{,}457 * (1/11 - 1/20))$ / $1000 * 3412)$/1,000,000

= $24.4\ MMBtu$

GSHPSiteWaterImpact$_{Gas}$ = $(\%DHWDisplaced * ((1/EF_{Gas} * GPD * Household * 365.25 * \gamma Water * (T_{OUT} - T_{in}) * 1.0)$ / 1,000,000

= $(0.44 * (1/0.8 * (100 * 672) * 8.33 * (125 - 50.7) * 1)$ / 1,000,000

= $22.9\ MMBtu$

SourceEnergySavings_PostAdj (MMBTUs) = 246.9 + 0 – 44.9 + 24.4 + 22.9 = 249.3 MMBtu

Savings would be claimed as follows:

Measure supported by:	Electric Utility claims:	Gas Utility claims:
Electric utility only	First 6 years: 274.4 * 1,000,000 / 3412 = 80,422 kWh Remaining 10 years: 249.3 * 1,000,000 / 3412 = 73,066 kWh	N/A
Electric and gas utility	First 6 years: 0.5 * 274.4 * 1,000,000 / 3412 = 40,211 kWh Remaining 10 years: 0.5 * 249.3 * 1,000,000 / 3412 = 36,533 kWh	First 6 years: 0.5 * 274.4 * 10 = 1372 Therms Remaining 10 years: 0.5 * 249.3 * 10 = 1247 Therms
Gas utility only	N/A	First 6 years: 274.4 * 10 = 2744 Therms Remaining 10 years: 249.3 * 10 = 2493 Therms

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (Capacity_{Cool} * (1/EER2_{base} - 1/EER2_{GSHP}))/1000 * CF$$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)
= 91.3%[1027]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during peak period)
= 47.8%[1028]

New Construction or Time of Sale:

For example, a 10 ton closed loop unit with Full Load EER rating of 20:

$\Delta kW_{SSP} = (120{,}000 * (1/11 - 1/20))/1000 * 0.913$
$= 4.482kW$

$\Delta kW_{PJM} = (36{,}000 * (1/11 - 1/20))/1000 * 0.478$
$= 2.347kW$

Early Replacement:

For example, a 10 ton closed loop unit with Full Load 20 EER replaces an existing working Air Source Heat Pump with 8.2 EER:

ΔkW_{SSP} for remaining life of existing unit (1st 8 years):
$= (120{,}000 * (1/8.2 - 1/20))/1000 * 0.913$
$= 7.883\ kW$

ΔkW_{SSP} for remaining measure life (next 17 years):
$= (120{,}000 * (1/11 - 1/20))/1000 * 0.913$
$= 4.482kW$

ΔkW_{PJM} for remaining life of existing unit (1st 8 years):
$= (120{,}000 * (1/8.2 - 1/20))/1000 * 0.478$
$= 4.127\ kW$

ΔkW_{PJM} for remaining measure life (next 17 years):
$= (120{,}000 * (1/11 - 1/20))/1000 * 0.478$
$= 2.347kW$

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

[1027] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[1028] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from gas to electric.

For the purposes of forecasting load reductions due to fuel switch GSHP projects; changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure. For Early Replacement measures, the efficiency terms of the existing unit should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 7 years for furnace, 8 years for boilers or GSHP, 15 years for electric resistance), and the efficiency terms for a new baseline unit should be used for the remaining years of the measure.

ΔTherms = $[Heating\ Consumption\ Replaced] + [DHW\ Savings\ if\ existing\ natural\ gas\ DHW]$

= $[(HeatLoad * 1\ AFUE_{base})/ 100{,}000] + [(1 - ElecDHW) * \%DHW * (1/ EF_{GasBase} * HotWaterUse_{Gallon} * \gamma Water * (T_{OUT} - T_{in}) * 1.0) / 100{,}000)]$

ΔkWh = $[FurnaceFanSavings] - [GSHP\ heating\ consumption] + [Cooling\ savings] + [DHW\ savings\ if\ existing\ electric\ DHW]$

=$[FurnaceFlag * HeatLoad * 1/AFUE_{base} * F_e * 0.000293] - [(HeatLoad * (1/ COP_{GSHP} * 3.412))/1000] + [(EFLH_{cool} * Capacity_{Cool} * (1/EER2_{\ base} - 1/EER2_{GSHP}))/1000] + [ElecDHW * \%DHW * ((1/EF_{ELEC} * HotWaterUse_{Gallon} * \gamma Water * (T_{OUT} - T_{in}) * 1.0) / 3412)]$

Illustrative Example of Cost Effectiveness Inputs for Fuel Switching:

For example, a 10 ton unit with Part Load EER rating of 20 and Part Load COP of 4.4 in an Assisted living building in Chicago with a 100 gallon gas water heater replaces an existing working natural gas boiler with 75% efficiency and air-cooled chiller of 9.5 EER. [Note the calculation provides the annual savings for the first 8 years of the measure life, an additional calculation (not shown) would be required to calculate the annual savings for the remaining life (years 9-25)]:

ΔTherms $=[HeatLoad * 1\ AFUE_{base})/\ 100{,}000] + [(1 - ElecDHW) * \%DHW * (1/ EF_{GasBase} * HotWaterUse_{Gallon} * \gamma Water * (T_{OUT} - T_{in}) * 1.0) / 100{,}000)]$

$=[(120{,}000 * 1{,}646 * 1/0.75)/100{,}000] + [((1 - 0) * 0.44 * (1/0.8 * (100 * 672) * 8.33 * (125 - 50.7) * 1\ )/100{,}000)]$

$= 2{,}634 + 229$

$= 2{,}863\ therms$

REVIEW DEADLINE: 1/1/2028

4.4.45 Adsorbent Air Cleaning

DESCRIPTION

The Adsorbent Air Cleaning (AAC) measure installs modular adsorbent air cleaning devices ("AAC modules") into commercial forced air HVAC systems. These devices pass return air through adsorbent media which remove the gas-phase contaminants carbon dioxide and species of volatile organic compounds (VOCs) from the return air, allowing it to be recirculated rather than removed from the building as exhaust and replaced with ventilation air. This allows HVAC system operators to substantially reduce the amount of outside air brought in for ventilation while still maintaining acceptable indoor air quality, resulting in heating and cooling energy savings. An energy penalty is incurred due to the operation of fans integrated within the AAC modules, as well as from integrated electric heaters used in a regeneration cycle which purges the adsorbent media of contaminants to allow them to be used again. Net energy savings are calculated and are equal to the cooling and heating energy savings due to reduced outdoor air minus the energy required to operate the AAC modules.

This measure serves the market for medium to large commercial and institutional buildings.

This measure is currently applicable to the following program types: NC, RF, DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Efficient equipment is defined as a commercial HVAC system which has AAC modules installed in the return airstream, with the number of modules determined by appropriate sizing calculations. The modules allow for a substantial reduction in the volume of outside air introduced to the building compared to systems without AAC modules.

DEFINITION OF BASELINE EQUIPMENT

Baseline equipment is a variable air volume HVAC system equipped with an integrated economizer and which does not have AAC modules installed. Heating is provided by either electricity, natural gas, or heat pump.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for HVAC applications is 20 years.[1029]

DEEMED MEASURE COST

Actual measure costs should be used if available. If costs are not available, the deemed measure cost below can be used, which is based on a cost per cfm of supply air flow rate.[1030]

Unit	Material Cost / Unit ($/cfm)	Labor Cost / Unit ($/cfm)	Total Cost / Unit ($/cfm)
Supply Air CFM	$0.90	$0.48	$1.38

For example, the default deemed measure cost of installing the AAC measure in an HVAC system with a design supply air flow rate of 75,000 cfm is:

Deemed Measure Cost ($) = 75,000 cfm * $1.38/cfm = $103,500

LOADSHAPE

For buildings with gas heat:

Loadshape C03 – Commercial Cooling

[1029] Expected lifetime based on median years of axial fans and dampers from the ASHRAE Equipment Life Expectancy Chart.
[1030] Default measure cost is based on sales information and labor cost estimates provided by a major Original Equipment Manufacturer (OEM) of AAC units. The OEM's estimates are based on prior installation experiences and case studies.

For buildings with electric heat:

Loadshape C05 – Commercial Electric Heating and Cooling

COINCIDENCE FACTOR

The concidence factor is assumed to be the PJM Summer Peak Coincidence Factor for Commercial Cooling:

CF_{PJM} = 47.8%[1031]

Algorithm

CALCULATION OF ENERGY SAVINGS

Savings associated with the Adsorbent Air Cleaning measure were derived from the results of a pilot study conducted in a commercial office building in Chicago during the 2019-2020 cooling and heating seasons. The building had a VAV system with economizer and electric heat. During the study, outdoor air rates were reduced according to the AAC module manufacturer's recommendations. Building cooling and heating loads associated with preconditioning outdoor air were continuously measured both with baseline and reduced outdoor air flow rates over a range of outdoor air temperatures and humidities. Statistical models were developed to predict energy and peak electric load savings as a function of outdoor air flow rate and outdoor air conditions. The models were then used to simulate energy use and peak load savings in other Illinois climate zones using TMY data.

In addition to monitoring cooling and heating energy, the pilot study also measured the electricity used to operate the AAC modules for the duration of the cooling and heating seasons. This energy penalty was subtracted from the cooling and heating load savings to calculate net savings.

ELECTRIC ENERGY SAVINGS

Identify the building's heating fuel. Electric energy savings will differ for buildings with natural gas, electric resistance, or electric heat pumps as a heating fuel.

For buildings with **natural gas** as a heating fuel, electric energy savings are:

$$\Delta kWh = \Delta VOA * (NCLS / Cooling_{COP} - Annual\ Electric_{AAC})$$

For buildings with **electric resistance** as a heating fuel, electric energy savings are:

$$\Delta kWh = \Delta VOA * (NCLS / Cooling_{COP} + NHLS - Annual\ Electric_{AAC})$$

For buildings with **electric heat pumps** as a heating fuel, electric energy savings are:

$$\Delta kWh = \Delta VOA * (NCLS / Cooling_{COP} + NHLS / Heating_{COP} - Annual\ Electric_{AAC})$$

Where:

ΔV_{OA} = reduction in minimum outside air flow in scfm due to incorporating an AAC module

= if the rate is unknown, calculate using the following equation:

$\Delta V_{OA} = V_{supply} * F_{OA} * F_R$, where:

V_{supply} = design or operational peak supply air flow rate of air handler in scfm

[1031] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

F_{OA} = operational minimum fraction of outside air in supply airflow before installing AAC modules

F_R = percentage reduction of outside air due to AAC modules

= custom; if unknown, use 0.7 as a default[1032]

NCLS (Normalized Cooling Load Savings)

= ΔkWh/Δscfm savings value for the appropriate climate zone in the table below:

Normalized Cooling Load Savings (kWh/cfm)				
Rockford – Zone 1	Chicago – Zone 2	Springfield – Zone 3	Mt. Vernon/Belleville – Zone 4	Marion – Zone 5
17.9	18.6	24.2	26.5	23.6

NHLS (Normalized Heating Load Savings)

= ΔkWh/Δscfm savings value for the appropriate climate zone and F_{OA} in the table below:

F_{OA}	Normalized Heating Load Savings (kWh/cfm)				
	Rockford – Zone 1	Chicago – Zone 2	Springfield – Zone 3	Mt. Vernon/Belleville – Zone 4	Marion – Zone 5
0.10	2.24	1.13	1.09	0.76	0.95
0.15	3.32	1.94	2.14	1.72	1.81
0.20	3.90	2.44	2.76	2.28	2.37
0.25	4.31	2.80	3.09	2.53	2.68
0.30	4.54	3.05	3.25	2.68	2.85

$Cooling_{COP}$ = seasonal average COP of building cooling plant. If unknown, use 4.0 as a default[1033]

$Heating_{COP}$ = seasonal average COP of heat pump. If unknown, use 2.5 as a default[1034]

Annual $Electric_{AAC}$ = annual electricity consumed by AAC modules for the appropriate climate zone

AAC Electricity Consumption (kWh/cfm)				
Rockford – Zone 1	Chicago – Zone 2	Springfield – Zone 3	Mt. Vernon/Belleville – Zone 4	Marion – Zone 5
1.07	0.91	1.06	0.98	0.89

[1032] The default value of 0.7 for FR is based on a survey of previous case studies which documented the field installation of AAC modules in existing HVAC systems.

[1033] The default cooling COP value of 4.0 is an approximation consistent with cooling analysis in the LEED rating system, and approximates a modern, moderate efficiency water-cooled chiller (COP = 6.0) with cooling tower and pump energy usage.

[1034] The default heating COP value of 2.5 is an approximation representing an air-source heat pump of moderate efficiency.

For example, office building in Climate Zone 3 is equipped with a VAV system with electric heat and has a cooling plant COP of 4.0, a design supply air flow rate of 50,000 scfm and an outdoor air ventilation rate of 10,000 scfm. Installing AAC modules will allow reduction of the outdoor air ventilation rate by 70%. In this case:

V_{supply} = 50,000 scfm

F_{OA} = 10,000 scfm / 50,000 scfm = 0.2

F_R = 0.7

$\Delta V_{OA} = V_{supply} * F_{OA} * F_R$ = 50,000 scfm * 0.2 * 0.7 = 7,000 scfm

Normalized Cooling Load Savings = 24.2 kWh/scfm (Climate zone 3, F_{OA} = 0.2)

$Cooling_{COP}$ = 4.0

Normalized Heating Load Savings = 2.76 kWh/scfm (Climate zone 3, F_{OA} = 0.2)

Annual $Electric_{AAC}$ = 1.06 kWh/scfm (Climate zone 3)

$\Delta kWh = \Delta V_{OA} * (NCLS / Cooling_{COP} + NHLS – Annual\ Electric_{AAC})$

= 7,000 scfm * (24.2 kWh/scfm / 4.0 + 2.76 kWh/scfm – 1.06 kWh/scfm)

= 54,250 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta V_{OA} * (Normalized\ Peak\ Cooling\ Load\ Savings / Cooling_{COP}) * CF_{PJM}$$

Where:

CF_{PJM} = 0.478

Normalized Peak Cooling Load Savings

= ΔkW/Δscfm savings value for the appropriate combination of building type, climate zone, and measure scenario, as detailed in the table below

Normalized Peak Cooling Load Savings (kW/cfm)				
Rockford – Zone 1	Chicago – Zone 2	Springfield – Zone 3	Mt. Vernon/Belleville – Zone 4	Marion – Zone 5
0.0259	0.0256	0.0296	0.0293	0.0283

FOSSIL FUEL SAVINGS

Natural gas savings do not apply to buildings where electricity is the heating fuel. For buildings where natural gas is the heating fuel:

$$\Delta therms = \Delta V_{OA} * (NHLS / \eta) * 0.03412$$

Where:

η = efficiency of gas heating equipment. If unknown, use 0.78 as default.

0.03412 = therms per kWh. Conversion factor to convert kWh to therms

MEASURE CODE: CI-HVC-ADAC-V04-240101

4.4.46 Server Room Temperature Set back

DESCRIPTION

This measure involves adjusting existing thermostats or building automation systems for reduced cooling energy consumption and fan energy consumption in server room and/or data center spaces. Existing set points should be documented through an audit or retro-commissioning study. A maximum temperature setpoint of 95°F will limit significant increase in server fan power consumption.

This measure was developed to be applicable to the following program types: RF, DI

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The criteria for this measure is established by optimizing the cooling temperature setpoint with a commercial thermostat or building automation system, up to a maximum of 95°F, which is adjusted to meet or approach ASHRAE recommended standards for data center cooling.

DEFINITION OF BASELINE EQUIPMENT

The baseline for this measure is a commercial thermostat or building automation system that is currently controlling cooling temperature setpoints that do not align with ASHRAE TC 9.9.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life of a programmable thermostat is assumed to be 8 years.[1035] For the purposes of claiming savings for an adjustment of an existing thermostat, this is reduced to a 50% persistence factor to give a final measure life of 4 years. It is recommended that this assumption be evaluated by future energy measurement and verification activities.

DEEMED MEASURE COST

Actual labor costs should be used if the implementation method allows. If unknown the labor cost for this measure is assumed to be $35.24 per thermostat,[1036] as summarized in the following table.

Measure	Units	Materials	Labor	Total Cost (including O&P)	City Cost Index (Install Only)*	Total	Source
Adjust Temperature Set Points	4	$0.00	$5.95	$6.55	134.5%	$35.24	RS Means 2010 (pg 255, Section 23-09-8100)
* Chicago, IL – Division 23							

LOADSHAPE

Loadshape C03 – Commercial Cooling

COINCIDENCE FACTOR

Since the server room is cooled 8760 hours, the summer peak coincidence factor is assumed to be 100%.

[1035] 8 years is based upon ASHRAE Applications (2003), Section 36, Table 3 estimate of 16 years for the equipment life, reduced by 50% to account for persistence issues.

[1036] RSMeans, "Instrumentation and Control for HVAC", Mechanical Cost Data , Kingston, MA: Reed Construction Data, 2010, pg. 255 & 632.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = Capacity * (1/EER) * EFLH * LF * \%Savings * (T_{after} - T_{before})$$

Where:

Capacity = Capacity of the cooling equipment actually installed in kBtu per hour (1 ton of cooling capacity equals 12 kBtu/hr)
= Actual

EER = Energy efficiency ratio of the equipment
= Actual

EFLH = Equivalent full load hours for cooling
= 8,760

LF = Load Factor,
= 65%[1037]

%Savings = Deemed percent savings
= 4% per degree increase[1038]

T_{after} = Space temperature setpoint after adjustment, maximum of 95°F
= Actual

T_{before} = Space temperature setpoint before adjustment
= Actual

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = Capacity * (1/EER) * LF * \%Savings * (T_{after} - T_{before}) * CF$$

4.4.47 Air Deflectors for Unit Ventilators – Provisional Measure – Removed V12.

4.4.48 Small Commercial Thermostats

DESCRIPTION

This measure characterizes the energy savings from the installation of either a Programmable or an advanced Thermostat to reduce heating and cooling consumption in a small commercial building.

The thermostat must be installed to control a single-zone HVAC system. This measure is limited to packaged HVAC units 10 tons or less. This measure should not be used when HVAC systems are being replaced, in new construction and whenever code compliance is required.

The savings associated with small commercial installations of thermostats had not been well evaluated at the time this measure was created for TRM Version 8.0. In the absence of assumptions specific to small commercial customers, the percent savings derived from Illinois Residential evaluations were used. In version 9.0 the cooling savings percentage was updated based on research conducted on small commercial programmable thermostat applications.[1039] In CY2020, additional research was performed to support a potential update to the heating savings percentage. The results did not provide a sufficient statistically significant basis for changing the current assumption.

Note that while these devices and service could potentially be used as part of a demand response program, the costs, delivery, impacts, and other aspects of DR-specific program delivery are not included in this characterization at this time, though they could be added in the future.

This measure was developed to be applicable to the following program types: TOS, RF, DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The criteria for this measure are established by replacement of a manual-only thermostat, with one that has the capability to establish a schedule of time and/or temperature setpoints, or replacement of a programmable thermostat with an Advanced Thermostat.

DEFINITION OF BASELINE EQUIPMENT

The baseline is assumed to be a manual or programmable thermostat.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 11 years.[1040]

DEEMED MEASURE COST

For DI and other programs for which installation services are provided, the actual material, labor, and other costs should be used. If unknown then the average incremental cost for the new installation measure is assumed to be $175.

LOADSHAPE

Loadshape C05 – Commercial Electric Heating and Cooling, or

Loadshape C03 – Commercial Cooling

COINCIDENCE FACTOR

In the absence of conclusive results from empirical studies on peak savings, the TAC agreed to a temporary assumption of 50% of the cooling coincidence factor, acknowledging that while the savings from the Thermostat will

[1039] See "Small Commercial Thermostats Research," memorandum from Guidehouse to ComEd dated May 15, 2020.
[1040] Based on 2017 Residential Smart Thermostat Workpaper, prepared by SCE and Nest for SCE (Work Paper SCE17HC054, Revision #0). Estimate ability of smart systems to continue providing savings after disconnection and conduct statistical survival analysis which yields 9.2-13.8 year range.

track with the cooling load, the impact during peak periods may be lower. This is an assumption that could use future evaluation to improve these estimates.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 45.7 [1041]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 23.9% [1042]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Heating savings are provided based upon the percentage savings from the Residential version of this measure. Cooling savings are based on research on small commercial programmable thermostat installations. Future research on heating savings percentages for small commercial applications, and heating and cooling savings percentages for Advanced Thermostat applications, should be used to improve this assumption.

ΔkWh[1043] $= \Delta kWh_{heating} + \Delta kWh_{cooling}$

$\Delta kWh_{heating} = (\%ElecHeat * kBtu/hr_{heat} * 1/\eta Heat_Electric * EFLH_{heat} * Heating_Reduction * BAF) + (\Delta Therms * F_e * 29.3)$

$\Delta kWh_{cool} = kBtu/hr_{cool} * 1/\eta Cool * EFLH_{cool} * Cooling_Reduction * BAF$

Where:

%ElecHeat = Percentage of heating savings assumed to be electric

= 1 if electric heat, 0 if gas heat. If unknown assume 0.08[1044].

$kBtu/hr_{heat}$ = capacity of the heating equipment in kBtu per hour.

= Actual. If unknown assume 114.5[1045]

ηHeat_Electric = Heating Seasonal Performance Factor of the equipment * Distribution efficiency

= Actual (assuming distribution efficiency of 0.95), if unknown a blended baseline value of 4.6 HSPF2[1046].

$EFLH_{heat}$ = Heating mode equivalent full load hours in Existing Buildings are provided in section 4.4 HVAC End Use.

[1041] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year. Multiplied by 50%.

[1042] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year. Multiplied by 50%.

[1043] Electrical savings are a function of both heating and cooling energy usage reductions. For heating this is a function of the percent of electric heat (heat pumps) and fan savings in the case of a natural gas furnace.

[1044] Based on percentage of customers in ComEd Small Business Thermostat program with electric heat.

[1045] Average capacity of 705 installs of thermostats in Ameren Illinois territory installed from 2015-2020.

[1046] Blended Baseline value came from percentage of accounts with heat pumps (15%) at 7.4 HSPF2 and electric furnaces (85%) at 3.412 HSPF, based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note HSPF value converted to HSPF2 by multiplying by 0.85, and then to estimate duct losses multiplied by 0.95.

Heating_Reduction = Assumed percentage reduction in total building heating energy consumption due to thermostat

= 8.8%[1047]

ΔTherms = Therm savings if Natural Gas heating system

= See calculation in Fossil Fuel section below

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 7.7%[1048]

29.3 = kWh per therm

$kBtu/hr_{cool}$ = capacity of the cooling equipment actually installed in kBtu per hour (1 ton of cooling capacity equals 12 kBtu/hr)

= Actual. If unknown assume 61.0[1049]

ηCool = Seasonal Energy Efficiency Ratio of the cooling equipment * Distribution Efficiency

= Actual, is unknown assume Code base, and assume 95% distribution efficiency for central cooling with ducts. For midstream programs, assume a value of 11.1 SEER2.[1050]

$EFLH_{cool}$ = Equivalent Full Load Hours for cooling in Existing Buildings are provided in section 4.4 HVAC End Use.

Cooling_Reduction = Average percentage reduction in total building cooling energy consumption due to installation of thermostat:

= 17.7%[1051]

BAF = Baseline adjustment factor.

= 1.0, if the baseline thermostat was manual type

[1047] Assumed equal to assumption for Residential Advanced Thermostats with manual thermostat baseline, before adding savings from Thermostat Optimization (which is not applicable to small commercial customers). Note that a Guidehouse billing study in CY2020 did not find a statistically significant basis for adjusting this assumption for commercial applications, see "Small Commercial Thermostats TRM Research" memo. April 21, 2021.
Estimates of heating and cooling reduction factors are based on consumption data analyses with matching to non-participants and are therefore net with respect to participant spillover and between net and gross with respect to free ridership. Like all consumption data analyses, they are gross with respect to non-participant spillover. For more detail, see Table 5-3 in Volume 4 of the IL-TRM. Consistent with Section 7.2 of the Illinois EE Policy Manual, applicable net-to-gross adjustments to these factors will be determined as part of the annual SAG net-to-gross process.

[1048] F_e is estimated using TRM models for the three most popular building types for programmable thermostats: low-rise office (10.2%), sit-down restaurant (8.6%), and retail – strip mall (4.4%). 7.7% reflects the average Fe of the three building types. See "Fan Energy Factor Example Calculation 2021-06-23.xlsx" for reference.

[1049] Average capacity of 639 installs of thermostats on units <=10tons in Ameren Illinois territory installed from 2015-2020 and 706 installs on units <=10tons in ComEd territory in 2021.

[1050] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER value converted to SEER2 by multiplying by 0.95, and multiplied by 0.95 distribution efficiency.

[1051] Based on research conducted by Guidehouse on a sample of IL Small Commercial programmable thermostat installations, which found a range of savings values depending on the modeling assumptions used. Guidehouse recommended selecting the midpoint of this range, which it deemed preferable to continuing to rely on Residential assumptions, while also accounting for the relative uncertainties involved. See "Small Commercial Thermostats Research" memo completed in 2020.
Estimates of heating and cooling reduction factors are based on consumption data analyses with matching to non-participants and are therefore net with respect to participant spillover and between net and gross with respect to free ridership. Like all consumption data analyses, they are gross with respect to non-participant spillover. For more detail, see Table 5-3 in Volume 4 of the IL-TRM. Consistent with Section 7.2 of the Illinois EE Policy Manual, applicable net-to-gross adjustments to these factors will be determined as part of the annual SAG net-to-gross process.

= 0.6, if the baseline thermostat was programmable type[1052]

= 0.8, if the baseline is unknown[1053]

For example, a thermostat installed in a Drug Store in Rockford with an electric heating system, replacing a manual type thermostat would have the following savings:

ΔkWh Heating = 1 * 114.5 * 1/4.6 * 2,848 * 8.8% * 1

= 6,238

ΔkWh Cooling = 61 * 1/11.1 * 858 * 17.7% * 1

= 835

ΔkWh = 6,238 + 835

= 7,073 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = $kBtu/hr_{cool} * 1/EER2 * Cooling_Reduction * BAF * CF$

Where:

EER2 = Energy Efficiency Ratio of the equipment

= Actual, if unknown assume current Code. For midstream programs, assume a value of 10.2 EER2.[1054] For air-cooled units < 65 kBtu/hr, assume the following conversion from SEER to EER for calculation of peak savings:[1055]

$$EER = (-0.02 * SEER^2) + (1.12 * SEER)$$

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 45.7% [1056]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 23.9% [1057]

Other variables as provided above.

[1052] This factor represents the ratio of thermostat adjustment savings to thermostat replacement savings. It is based on actual thermostat algorithm data (i.e., degrees of setback, hours values, fan modes) from two years of ComEd AirCare Plus Program data (PY9+ and CY2018), including 382 thermostat adjustment installations and 3,847 thermostat replacement installations. An analysis of the data showed that on average, thermostat adjustments saved 61% and 59% of the thermostat replacement cooling savings and heating savings, respectively. For simplicity, a value of 0.6 was selected for both cooling and heating savings adjustment. See IL TRM Workpaper "4.4.48 Small Commercial Thermostats", Guidehouse, 6/23/2021 for details.

[1053] Review of ComEd's 2020 Baseline Study and 2019-2020 Program Data indicates that approximately half of installs are in buildings with existing manual thermostats, and half with existing programmable thermostats.

[1054] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note EER value converted to EER2 by multiplying by 0.95, and multiplied by 0.95 distribution efficiency.

[1055] Based on Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder. Note this is appropriate for single speed units only.

[1056] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year. Multiplied by 50%.

[1057] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year. Multiplied by 50%.

For example, a thermostat installed through a midstream program in a Drug Store in Rockford with an electric heating system, replacing a manual type thermostat would have the following savings during system peak hours:

ΔkW = 61 * 1/10.2* 17.7% *1 * 45.7%

= 0.48 kW

FOSSIL FUEL SAVINGS

$$\Delta Therms = ((1 - \%ElectricHeat) * EFLH_{heat} * Capacity * 1/\eta Heat_Fossil * Heating_Reduction * BAF)/ 100{,}000 Btu/Therm$$

Where:

Capacity = Nominal Heating Input Capacity (Btu/hr) of heating system

= Actual

ηHeat_Fossil = Annual Fuel Utilization Efficiency Rating * Distribution Efficiency

= Actual, if unknown assume code baseline and assume 95% distribution efficiency. For midstream prorams, assume a value of 0.821.[1058]

Other variables as provided above.

For Example, a thermostat installed through a midstream program in a Drug Store in Rockford with a gas heating system with a rated capacity of 60,000 Btu/hr, replacing a manual type thermostat would have the following savings:

ΔTherms = ((1 - 0) * 2,848 * 60,000 * 1 / 0.821 * 8.8% * 1) / 100,000

= 183 Therms

[1058] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

4.4.49 Boiler Chemical Descaling

DESCRIPTION

The measure is for a non-residential hot water or steam boiler serving process loads or one that provides space heating. Even with careful and precise water treatment in a boiler system, mineral scales are formed over time due to the high pressure and heat. Boiler scale is typically calcium, carbon, iron and silica particle deposits that form on the boiler tubes. Scale creates a problem because it typically possesses a thermal conductivity, an order of magnitude less than the corresponding value for bare steel. Even thin layers of scale serve as an effective insulator and inhibit heat transfer. The result is overheating of boiler tube metal, tube failures, and loss of energy efficiency.

De-scaling a boiler system will improve boiler efficiency by removing mineral scale build up on boiler tubes. De-scaling is done either through mechanical or chemical cleaning techniques. There are several limitations to mechanical cleaning, namely firetube boilers cannot be mechanically cleaned. Depending on the size of the boiler, it can take up to a week to mechanically clean the tubes. This measure applies to chemical de-scaling, which is an efficient alternative, since it is not plagued by these limitations. The procedure typically involves the boiler being emptied and taken off-line, following which, the correct chemical solution ratio is pumped through the boiler system for four to eight hours.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the facility must, as applicable, complete the chemical de-scaling by an approved technician and be NSF/ANSI/CAN 60 compliant.[1059]

The efficient equipment is a boiler system which has been de-scaled using a chemical solution. After the cleaning is complete, the personnel have to ensure that all safety checks are completed including checks for leaks. Lastly, any remains of the descaling chemical solution have to be eliminated from the tubes by flushing the system with water and a blowdown.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a boiler system that is compromised by scale build up.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The lifetime of this measure varies based on the location of the site in Illinois. It has been established that the rate of scale buildup in hydronic systems is directly dependent on the hardness of the supply water (the amount of dissolved Calcium, Magnesium and Iron).[1060] Based on an analysis of water supply composition in Illinois,[1061] the estimated life of measure(in years) before requiring de-scaling is listed below:

Climate Zone	Measure Life of De-scaling
Rockford	2
Chicago	6
Springfield	2

[1059] NSF/ANSI/CAN 60 Standard: "If you manufacture, sell or distribute water treatment chemicals in North America, your products are required to comply with NSF/ANSI/CAN 60: Drinking Water Treatment Chemicals – Health Effects by most governmental agencies that regulate drinking water supplies."

[1060] 'Study on Benefits of Removal of Water Hardness (Calcium and Magnesium Ions) from a Water Supply', Battelle Memorial Institute, accessed April 2020.

[1061] The Water Quality Reports from 'Illinois American Water' were analyzed for all five TRM zones in Illinois. Based on the water hardness level and Iron content, a correlation was made to the estimated usage of hydronic equipment before de-scaling is required. See page v of 'Study on Benefits of Removal of Water Hardness (Calcium and Magnesium Ions) from a Water Supply', Battelle Memorial Institute and "Water Quality Summary.xlsx" for reference.

Climate Zone	Measure Life of De-scaling
Belleville	3
Marion	3

DEEMED MEASURE COST

The cost of this measure is estimated to be $378/MMBtu/hr per boiler.[1062]

FOSSIL FUEL SAVINGS

$$\Delta\text{Therms} = (Capacity * EFLH * \%Ei) / 100{,}000$$

Where:

Capacity = Nominal Heating Input Capacity Boiler Size (Btu/hr) for boiler unit

= Actual

EFLH = Equivalent Full Load Hours for heating in Existing Buildings are provided in section 4.4 HVAC End Use. For process loads, use custom hours.

%Ei = Percent efficiency improvement from chemical descaling

= Dependent on system pressure and estimate of scale thickness. If unknown assume normal.[1063]

[1062] Averaged from quotes from two chemical de-scaling solution manufacturers. Quote based on one day service with two personnel, including circulating pumps, tank assembly and other necessary fittings. Quotes based on pilot project study done by Nicor Gas Emerging Technology Program and Gas Technology Institute (GTI), "Descaling of Steam Boiler Systems", 2019-2020. A 20% RYDLYME solution is assumed for cost, based on the pilot.

[1063] Estimates based on pilot project study done by Nicor Gas Emerging Technology Program and Gas Technology Institute (GTI), "Descaling of Steam Boiler Systems", 2019-2020, and review of the following studies:
'Clean Firetube Boiler Waterside Heat Transfer Surfaces', U.S. Department of Energy, April 2012.
'Energy Conservation Program Guide for Industry and Commerce', NBS Handbook 115 Supplement 1, U.S. Department of Energy, December 1975, accessed April 2020.

	Efficiency Improvement (%Ei)	
Scale Thickness (inches)	Low Pressure (15psig and below) Applications	High Pressure (above 15psig) Applications
Low (≤1/64)	1%	1.6%
Normal (≥1/32 & ≤ 3/64)	2.5%	3.9%
High (≥1/16)	3.9%	6.2%

100,000 = Converts Btu to Therms

For example, a 10,000 MBH firetube steam boiler in a Manufacturing facility in Rockford. The scaling on the tubes was estimated to be of 'normal' thickness and the steam supply was 'low pressure' at 15 psig.

ΔTherms = (Capacity * EFLH * %Ei) / 100,000

= (10,000,000 * 1,048 * 0.025) / 100,000

= 2,620 Therms

4.4.50 Electric Chillers with Integrated Variable Speed Drives – Removed V12

4.4.51 Advanced Rooftop Controls with High Rotor Pole Switch Reluctance Motors

DESCRIPTION

A High Rotor Pole Switch Reluctance Motor (HRSRM) is a type of brushless DC electric motor that runs by reluctance torque. Unlike other DC motor types, power is delivered to windings in the stator rather than the rotor. This simplifies the mechanical design; power does not need to be delivered to a moving part, but requires a switching system through software control to deliver power to the different windings. Electronic devices can precisely time switch, facilitating HRSRM configurations.

In applications on rooftop units (RTUs), the HRSRM motor is comparable or more efficient than an RTU equipped with a variable speed drive supply fan. It results in fan-energy savings and can also include cooling savings if coupled with compressor or ventilation control, compared to a baseline scenario of constant-volume, constant-ventilation operation that is typical of single-zone, packaged HVAC units.

Fan energy savings come from the new integrated motor controls that allow for higher efficiency at varying loads and is achieved in all applications. Cooling savings can also be added from the effective use of variable speed or multi-stage cooling.

The markets that can be served by HRSRM motors are those which utilize RTUs, including but not limited to:

1 Fast-Service Restaurant
2 Full-Service Restaurant
3 Small Office
4 Stand-Alone Retail
5 Strip Mall
6 Warehouse

This measure was developed to be applicable to the following program types: NC, RF, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is a single-zone, packaged HVAC unit with an existing functional integrated economizer that has been fitted with a HRSRM supply-fan and integrated speed control. This applies to both retrofit and new construction, and early replacement applications.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a single-zone, packaged HVAC unit (with an existing functional integrated economizer) that lacks demand-controlled ventilation controls and lacks supply-fan speed control via a variable-frequency drive.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 12 years based on the HRSRM life.[1064]

DEEMED MEASURE COST

Actual measure costs should be used if available. If costs are not available, the deemed measure cost below can be used. Material cost is based on the horsepower (hp) of the supply fan used in the RTU. Retrofit represents the full cost of the installation. New construction and early replacement represent the incremental cost of the motor itself on a new unit.[1065]

[1064] Based on life cycle of a switch reluctance motor from P. Andrada, B. Blanque, E. Martınez, J.I. Perat, J.A. Sanchez, and M. Torrent, "Environmental and life cycle cost analysis of one switched reluctance motor drive and two inverter-fed induction motor drives," IET Electric Power Applications (2010): page 8.

= 47.8%[1067]

[1066] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1067] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year

Algorithm

CALCULATION OF ENERGY SAVINGS

Six different building types were selected for study. OpenStudio measures were used to generate ASHRAE 90.1-2013 code-compliant DOE prototype baseline models for each building type. The total conditioned area, the number of conditioned zones, and the peak cooling demand for each building are summarized in the following table.[1068]

Selected DOE Prototype Buildings

Building Type	Small Office	Stand-Alone Retail	Warehouse	Strip Mall	Fast-Service Restaurant	Full-Service Restaurant
Conditioned Area (ft2)	5,502	24,692	52,045	22,500	2,501	5,502
Number of Conditioned Zones	5	4	3	10	2	2
Total Fan Break Horsepower (BHP)	3.5	25	5	23	7	11
Design Cooling Load (Ton)	8.5	65	13	69	20	33

In order to achieve savings, the RTU control options consist of following modes:

1. Ventilation Mode:
    a. Outdoor air is at a minimum for building type
    b. Fan speed set to 40%
    c. Heating and cooling coils are off
2. Economizer Mode
    a. Outdoor air rate was set from 40% and increased as needed to satisfy indoor air temperature
    b. When outdoor air could no longer satisfy cooling, cooling mode was staged on
3. Mechanical Cooling Mode
    a. Outdoor air is at a minimum for building type
    b. Compressors (if multiple or variable) were staged/modulated to meet setpoint temperature of the space
    c. Supply fan set to 100%
4. Heating mode
    a. Outdoor air is at a minimum for building type
    b. Heating coil staged as necessary
    c. Supply fan set to 100%

The models produced a percentage energy savings based on using a HRSRM fan and varying compressor types. Retrofit savings include fan only. For new construction and early replacement, savings are based on compressor type and energy efficiency of the unit. These RTU control options are reflected in the table below. As a correction to these entries, a second set of single two-stage compressor RTU fan options are also reflected in the *Energy Savings Type: ESF_Fan* entry in the table below[1069] and are characterized by the following speed settings:

1. Ventilation Mode:
    a. Outdoor air is at a minimum for building type
    b. Supply fan set to 40%
    c. Heating and cooling coils are off

[1068] Korbaga Woldekidan, Daniel Studer, and Ramin Faramarzi, "Performance Evaluation of Three RTU Energy Efficiency Technologies," 2019.

[1069] Lick, A., A. Cardiel, J. Zhou, S. Hackel, S. Pigg, and K. Gries. "Switched-Reluctance Motor Field Evaluation Final Report." Slipstream project report for the ComEd Energy Efficiency Program. March 25, 2022. https://comedemergingtech.com/project/srm-field-evaluation

2. Economizer Mode:
    a. No change compared to existing RTU settings
3. Mechanical Cooling Mode (Stage 1):
    a. Outdoor air is at a minimum for building type
    b. Compressor stage 1 ON
    c. Supply fan set to 75%
4. Mechanical Cooling Mode (Stage 2):
    a. Outdoor air is at a minimum for building type
    b. Compressor stage 1 & 2 ON
    c. Supply fan set to 90%
5. Heating Mode:
    a. Outdoor air is at a minimum for building type
    b. Heating coil staged as necessary
    c. Supply fan set to 90%

ELECTRIC ENERGY SAVINGS

For units with cooling capacities less than 65 kBtu/hr:

$$\Delta kWH = (kBtu/hr) * (1/SEER2_{exist}) * EFLH * ESF_Cooling + 0.746 * FanHP * (LF/\eta_{motor}) * RunHours * ESF_Fan$$

For units with cooling capacities equal to or greater than 65 kBtu/hr:

$$\Delta kWH = (kBtu/hr) * (1/IEER_{exist}) * EFLH * ESF_Cooling + 0.746 * FanHP * (LF/\eta_{motor}) * RunHours * ESF_Fan$$

Where:

kBtu/hr = capacity of the cooling equipment in kBtu per hour (1 ton of cooling capacity equals 12 kBtu/hr)

$SEER2_{exist}$ = Seasonal Energy Efficiency Ratio of the existing equipment * Distribution Efficiency

= Actual. Or assume Code base in place at the original time of existing unit installation. IECC 2018 (effective July 1, 2019 to December 31, 2023) and IECC 2021 (effective statewide January 1, 2024) provided below for referenced, and assume distribution efficiency of 0.95. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints. If unknown, assume a value of 11.1 SEER2.[1070]

$IEER_{exist}$ = Integrated Energy Efficiency Ratio of the existing equipment * Distribution Efficiency

= Actual. Or assume Code base in place at the original time of existing unit installation. IECC 2018 (effective July 1, 2019 to December 31, 2023) and IECC 2021 (effective statewide in January 1, 2024) provided below for reference, and assume distribution efficiency of 0.95. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

EFLH = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in Illinois TRM version 8.0 section 4.4 HVAC End Use

ESF_Cooling = Energy savings factor for cooling as found in **Error! Reference source not found.**[1071]

[1070] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER value converted to SEER2 by multiplying by 0.95, and multiply by 0.95 distribution efficiency.

[1071] Average cooling savings for all building types from paper entitled "Performance Evaluation of Three RTU Energy Efficiency Technologies", NREL and ComEd, December 2020. Savings averaged by RTU compressor type.

ESF_Fan = Energy savings factor for cooling as found in table below[1072]

Energy Savings Factors

Energy Savings Type	Retrofit Type	HRSRM on Single Stage Compressor	HRSRM on Single Two Stage Compressor	HRSRM on Variable Speed Compressor
ESF_Cooling[1073]	New Construction/Early Replacement	0%	0%	0%
ESF_Cooling[1074]	Supply Fan Retrofit Only	0.0%	0.0%	0.0%
ESF_Fan[1074]	New Construction/Early Replacement	46.6%	61.0%	64.8%
ESF_Fan[1074]	Supply Fan Retrofit Only	46.6%	61.0%	64.8%

FanHP = Horsepower of fan in RTU

= Actual

LF = Load Factor; Motor Load at Fan Design CFM (Default = 65%)[1075]

η_{motor} = Installed nominal/nameplate motor efficiency

Default motor is a NEMA Premium efficiency, ODP, 4-pole/1800 RPM fan motor

4.4.52 Hydronic Heating Radiator Replacement

DESCRIPTION

A hydronic heating radiator's capacity to evenly and consistently distribute heat throughout a space, utilizing piped hot-water or steam is often stymied by the buildup of mineral deposits and contaminates. Past research has shown that eliminating these deposits regularizes flow rate and boiler behavior, in effect restoring a radiator to a like-new condition.[1079] A space is heated more effectively in this improved state and this condition furthermore reduces the need for continual (additionally wasteful) thermostat readjustment. A straightforward process to achieve this is to simply replace the fouled hydronic radiator pipe system with a new system equivalent to the replaced system's pre-fouled performance levels. This avoids any possible inconsistencies associated with a radiator-flushing procedure (e.g., less-than-expected savings, failure to return the pipe system to like-new condition, inability to treat a system due to its interlinking with separate domestic hot water systems, etc.) and furthermore ensures that expected savings are realized. This measure offers benefits during heating seasons for natural gas, is applicable to both residential and commercial applications, and considers hot water or steam as the source of thermal energy (seeing as both heat transfer mediums can theoretically act as the intermediary from which contaminates precipitate).

The calculations of savings presented in this section are furthermore normalized to apply to both commercial and multi-family residential applications and additionally consider the differences between the physical characteristics of hot water or steam (e.g., thermal resistance, temperature, convective heat transfer) when computing the savings tabulated in the 'Annual Normalized Gas Savings per Surface Area' table shown below.

This measure was developed to be applicable to the following program types: RF

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is a new replacement hydronic radiator free of mineral deposit scaling and/or sludge which must reflect the capacity of the replaced system's pre-fouled performance levels (i.e., a "like-for-like" replacement).

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is the hydronic radiator being replaced, which has shown decreased performance due to a high degree of mineral deposit scaling and sludge buildup. The built-up scale inside the radiators is predominantly assumed to be Iron Oxide (Fe_3O_4) and to have a thermal conductivity of 3.01 Btu/hr·ft·°F.[1080]

A "standard scaled" radiator is assumed to be 10% clogged and a "heavily scaled" radiator is assumed to be 30% clogged. An implementation contractor will need to verify the baseline condition of the radiator, to classify it as either standard or heavily scaled. Measuring the surface temperature spread using an infrared temperature thermometer can be used to determine this; surface temperature spot readings below 180°F for a steam system and below 100°F for a hot water system can be labeled as 'standard scaling'. A "heavily scaled" radiator is assumed to one with surface temperature spots below 150°F for a steam system and below 90°F for a hot water system.[1081] This should be verified by the implementation contractor by measuring the radiator surface temperature at multiple points when operating the boiler system at full load and when outdoor air temperatures are below 20°F. Implementer should strive to perform spot readings on at least 10% of total radiators. Based on the collected spot temperature readings, qualify the facility as either standard scaled or heavily scaled.

[1079] Day, Paul and Balmer, Paul. "Independent Study Shows Sludge Build-up Significantly Affects Hydronic Heating System Performance," May, 2011. Accessed 03/25/20.

[1080] The thermal properties of Iron Oxide are referenced from the following: Takeda, Mikako and Onishi, Takashi and Nakakubo, Shouhei and Fujimoto, Shinji. "Physical Properties of Iron-Oxide Scales on Si-Containing Steels at High Temperature," Materials Transactions Vol 50, No. 9 (2009): pp. 2242-2246. dio:10.2320/matertrans.M2009097.

[1081] Assumptions based on typical operating hot water/steam supply temperatures for cast-iron radiators of 170°F and 220°F. 'Clogged' surface temperature assumptions based on temperatures below which performance of radiators starts dropping considerably.

The baseline for this measure is aging scaled radiators. Most facilities tend not to replace their old radiators and often tend to add a means of secondary heating. This measure is aimed at these facilities to incentivize the replacement of these old radiators.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

Hydronic radiator systems are extremely diverse, in size, scope or application, and in the materials utilized for the heat transfer surface. Cast iron, steel, and copper piping are common in radiators, as are polymer materials such as polyethylene (often seen in newer radiator systems). As such, an estimated useful life will naturally vary based on these circumstances and the quality of previous radiator maintenance. The estimated useful life of a typical hydronic radiator has been approximated to be 25 years.[1082]

DEEMED MEASURE COST

The measure cost is the full cost of removing the existing unit and installing a new one. The actual program cost should be used. If unknown, assume $61.35 per vertical column.[1083] For more details on the definition of section of a radiator, the cited reference can be used.[1084]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

N/A

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

The annual natural gas savings per area for radiator replacement is calculated by determining the difference between the heat transfer from the replacement radiator and the radiator being replaced.

$$\Delta Therms = \frac{\left[[Q_{New} - Q_{Base}] * EFLH\right]}{(100{,}000 * \eta)}$$

[1082] Examples from the following source use "system design lives" of 20 and 25 years, and cite the service lifetimes of a cast iron hydronic radiator's boiler to often be "30 years or more".
Siegenthaler, John, Modern Hydronic Heating: For Residential and Light Commercial Buildings 3rd Edition, Delmar Cengage Learning, Clifton Park, New York, 2012.
There is limited information available on system lifetimes of hydronic radiators, as well-built and well-maintained systems tend to last for decades. We assume that a midpoint of the "design-lifes" cited above (25) can correspond to the time a hydronic radiator system begins to underperform, with one known reason for underperformance (which also happens to be the focus of this measure) being the corrosion of piping materials and/or the presence of precipitated mineral contaminates restricting flow rate and thus hindering heat transfer.

[1083] Average calculated from RSMeans Cost Data 2020 for Hydronic Heating Radiators, Cast Iron.

[1084] Express Radiant, "Calculating Radiator Output", 2014. This reference shows a representation of how a section of a typical radiator is defined.

$$Q_{Base} = \frac{(A * \Delta T)}{R_{Base}}$$

$$R_{Base} = R_{conv1} + R_{cond} + \left(\frac{R_{rad} * R_{conv2}}{R_{rad} + R_{conv2}}\right)$$

$$Q_{New} = \frac{(A * \Delta T)}{R_{New}}$$

The thermal resistance components remain the same as the above (R_{Base}), with the exception of the contaminate oxide layer which is no longer present in the post-case:

$$R_{New} = R_{conv1} + \left(\frac{R_{rad} * R_{conv2}}{R_{rad} + R_{conv2}}\right)$$

Where:

Q_{New} (Btu/hr)	= The heat emission from the replacement hydronic heating system
Q_{Base} (Btu/hr)	= The heat emission from the hydronic heating system being replaced
$EFLH$	= Effective full load hours based on the climate zone

Heating Season Recirculation Hours

Climate Zone	Hours
1 – Rockford	5,039
2 – Chicago	4,963
3 – Springfield	4,495
4 – Belleville	4,021
5 – Marion	4,150

η	= Actual Thermal Efficiency of the Heating Equipment (if unknown, use 81.9% for water boilers[1085] and 80.7% for steam boilers[1086])
$100{,}000$	= conversion factor (1 Therm = 100,000 Btu)
A (ft^2)	= the effective area of heat transfer of the radiator[1087]
ΔT (°F)	= the temperature difference between the supply fluid temperature and the conditioned room design temperature
R_{Base} (ft2 °F hr/ BTU)	= the overall thermal resistance of the system before replacement
R_{New} (ft2 °F hr/ BTU)	= the overall thermal resistance of the system after replacement
R_{conv1}(ft2 °F hr/ BTU)	= the thermal resistance of convection between the hot water/steam and the radiator[1088]

[1085] Average efficiencies of units from the California Energy Commission (CEC).
[1086] Ibid.
[1087] The pipe diameter is assumed to be 2 inches and the thickness of mineral deposits in a fouled radiator (which, recall, are assumed to be composed of iron oxide), is a function of the percent of the pipe diameter which is clogged and the assumed pipe diameter.
[1088] For a steam system, the supply temperature is assumed to be 220°F. For a hot water system, the supply temperature is assumed to be 170°F. This implies convective heat transfer coefficients of 1,100 Btu/hr·ft^2·°F and 700 Btu/hr·ft^2·°F for steam and hot water, respectively, the inverses of which equate to steam's or hot water's thermal resistances.

R_{cond}(ft2 °F hr/ BTU) = the thermal resistance of conduction in the oxide layer buildup[1089]

R_{rad}(ft2 °F hr/ BTU) = the thermal resistance of radiation between the radiator and the conditioned space[1090]

R_{conv2}(ft2 °F hr/ BTU) = the thermal resistance of convection between radiator and the conditioned space[1091]

Annual Normalized Gas Savings per Surface Area (therms/ft^2)

HVAC System Type		1 – Rockford	2 – Chicago	3 – Springfield	4 – Belleville	5 – Marion
Hot Water Radiator	Standard Scaling	0.115	0.113	0.102	0.091	0.094
	Heavy Scaling	0.337	0.332	0.301	0.269	0.278
Steam Radiator	Standard Scaling	0.170	0.168	0.152	0.136	0.140
	Heavy Scaling	0.501	0.493	0.447	0.400	0.413

$$\Delta Therms = HS_{cz} * Area_{radiator}$$

Where:

HS_{cz} = Annual heating savings per area of radiator by climate zone, values from 'Annual Normalized Gas Savings per Surface Area' table above.

$Area_{radiator}$ = Total surface area of radiator (ft^2)

Example:

For example, a building in Climate Zone 1 is equipped with a heavily scaled steam radiator system. The surface area of the replacement and radiator being replaced was calculated to be 85 ft^2.

$\Delta Therms$ = Annual Normalized Gas Savings (therms/ft^2) * Surface Area (ft^2)

= 0.501 * 85

= 42.59 therms annually

MEASURE CODE: CI-HVC-HHRR-V02-240101

REVIEW DEADLINE: 1/1/2028

[1089] Recall that iron oxide has a thermal conductivity of 3.01 Btu/hr·ft^{2}·°F.

[1090] Stefan-Boltzmann constant is assumed to be 1.714×10^{-9} BTU·hr^{-1}·ft^{-2}·°R^{-4}.

[1091] The convective heat transfer coefficient of Air is assumed to be 1.844 Btu/hr·ft^{2}·°F. Emissivity of radiator surface is assumed to be 0.6.

4.4.53 HVAC Supply, Return and Exhaust Fans – Fan Energy Index

DESCRIPTION

The Fan Energy Index (FEI) is a new fan efficiency metric that allows for the comparison of different fans at application specific operating conditions. This is a significant improvement over the current Fan Efficiency Grade metric, which is defined at a rated condition. FEI is incorporated in ASHRAE 90.1-2019 and IECC-2021. These codes set the baseline FEI as 1.0 for constant speed fan operation and 0.95 for variable speed fan operation. More efficient fans will have FEI greater than these values. It is only applicable to stand-alone fans, and not for fans embedded in packaged equipment. This measure results in fan energy savings compared to a baseline scenario of an existing fan's FEI or code minimum FEI for a new fan.

Note this measure should be used for evaluating more efficient over baseline fans with the same control system. Measure 4.4.26 should be utilized to evaluate control system modifications. When combining the two measures, the FEP_{New} value should be used to replace the $\left(0.746 \times HP \times \frac{LF}{\eta_{motor}}\right)$ term in Measure 4.4.26 Variable Speed Drive for HVAC Supply and Return Fans.

This measure serves the market for commercial and industrial buildings.

This measure was developed to be applicable to the following program types: TOS, NC, and EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to exceed the efficiency requirements defined by the program.

DEFINITION OF BASELINE EQUIPMENT

For Time of Sale (TOS): The baseline equipment is assumed to meet the efficiency requirements within the IECC code in effect on the date of the building permit or sale (if unknown assume IECC 2021).

For New Construction (NC): The baseline equipment is assumed to meet the efficiency requirements within the IECC code in effect on the date of the building permit (if unknown assume IECC 2021). As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

For Early Replacement (EREP): The baseline equipment is assumed to be the existing fan.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

For variable speed fans, the expected measure life is 15 years.[1092]

For constant speed fans, the expected measure life is 18 years for centrifugal housed and unhoused fans. The expected measure life is 25 years for all other fan types.[1093]

DEEMED MEASURE COST

Actual measure costs should be used if available. Default measure costs are noted below for fans with FEI greater than 1.0[1094]. These costs are established at an FEI of 1.2. To calculate the cost for a fan with different FEI, prorate the default cost with the actual FEI (see example).

[1092] "NEEP Incremental Cost Study – Phase II Final Report, Navigant, 2013."

[1093] U.S. Department of Energy Fans and Blowers Working Group, Energy Conservation Program: Final Determination of Fans and Blowers as Covered Equipment

[1094] Costs are based on the U.S. Department of Energy Fans and Blowers Working Group spreadsheet: EERE-2013-BT-STD-0006-0189_attachment_1.xlsx.

TOS and NC

Fan Type	Cost ($/hp)	
	Small (< 10 hp)	Large (>= 10 hp)
Axial Cylindrical Housed	$264	$87
Panel	$29	$10
Centrifugal Housed	$199	$55
Centrifugal Unhoused	$76	$18
Inline and Mixed Flow	$297	$97
Radial	$119	$33
Power Roof Ventilator	$140	$42

EREP

Fan Type	Cost ($/hp)	
	Small (< 10 hp)	Large (>= 10 hp)
Axial Cylindrical Housed	$3,218	$1,068
Panel	$319	$104
Centrifugal Housed	$1,381	$382
Centrifugal Unhoused	$827	$195
Inline and Mixed Flow	$2,301	$751
Radial	$1,570	$434
Power Roof Ventilator	$1,536	$460

For example, the default deemed measure cost of installing a new construction, centrifugal housed, 5 hp fan with FEI = 1.3 is:

Deemed Measure Costs ($) = $199 per hp *5 hp * (1.3 / 1.2) = $1,078

LOADSHAPE

Loadshape C39 – VFD – Supply fans <10 HP

Loadshape C40 – VFD – Return fans <10 HP

Loadshape C41 – VFD – Exhaust fans <10 HP

COINCIDENCE FACTOR

The demand savings factor (DSF) is already based upon coincident savings, and thus there is no additional coincidence factor for this characterization.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Note this measure should be used for evaluating more efficient over baseline fans with the same control system. Measure 4.4.26 Variable Speed Drives for HVAC Supply and Return Fans should be utilized to evaluate control system modifications. When combining the two measures, the FEP_{New} value should be used to replace the $\left(0.746 \times HP \times \frac{LF}{\eta_{motor}}\right)$ term in Measure 4.4.26.

ΔkWh_{fan} = $$FEP_{New} * (\frac{FEI_{New}}{FEI_{Base}} - 1) * RHRS * \sum_{0\%}^{100\%} (\%FF * PLR)$$

ΔkWh_{total} = $$\Delta \mathrm{kWh}_{\mathrm{fan}} * (1 + \mathrm{IE}_{\mathrm{energy}})$$

Where:

ΔkWh_{fan} = Fan-only annual energy savings (kWh)

FEP_{New} = Fan Electrical Power of new fan at 100% flow fraction (kW)

FEI_{New} = Fan Energy Index of new fan at 100% flow fraction (-)

FEI_{Base} = Fan Energy Index of baseline fan at 100% flow fraction (-)

TOS and NC: FEI_{base} is defined per IECC.

= 0.95 for Variable Speed Fan

= 1.0 for Constant Speed Fan

EREP: FEI_{base} is defined as existing fan efficiency. If unknown, use:[1095]

Fan Type	Drive Type		
	Variable Speed – Belt	Constant Speed – Belt	Constant Speed – Direct
Axial Cylindrical Housed	0.88	0.88	0.97
Panel	0.95	0.95	0.88
Centrifugal Housed	0.92	0.92	0.92
Centrifugal Unhoused	0.94	0.94	1.03
Inline and Mixed Flow	0.79	0.79	0.77
Radial	0.81	0.81	0.94
Power Roof Ventilator	0.82	0.82	0.76

RHRS = Annual operating hours for fan based on building type

Default hours are provided for HVAC applications which vary by HVAC application and building type.[1096] When available (provided via Energy Management Software or metered), actual hours should be used.

4.4.54 Process Heating Boiler

DESCRIPTION

A process boiler is a pressure vessel that transfers heat to water for industrial process applications. Process boilers can be configured as an integrated packaged boiler or as modular instantaneous boiler arrays. This measure is applicable to boilers which serve process loads in a facility.

Modular instantaneous boilers are a recent addition to the industrial/commercial market aimed at addressing some of the drawbacks of conventional large boiler systems. They achieve high efficiencies by using multiple smaller sized modules to meet the minimum demand. They allow each boiler to operate at or close to full rated load most of the time, with reduced standby losses. The boiler design is a low water mass pressure vessel that produces steam at operating pressure rapidly then shuts off the combustion system once the demand requirement is met, thereby saving fuel.

Traditional packaged boiler systems are designed to provide the entire steam load of the facility using one or two boilers. Typically, the boiler horsepower is sized for the maximum steam load required at any facility. However, the average steam load of any facility is only 30 to 40 percent of this, and the average load on the boiler system is low. Therefore, they are not able to achieve these high efficiencies.[1099]

This measure was developed to be applicable to the following program types: NC, EREP, TOS.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is the replacement of a non-residential standard efficiency process boiler for process loads with a high-efficiency process boiler exceeding the energy conservation standards outlined below. The efficient unit may either be a conventional packaged boiler or a modular boiler array system. Non-residential commercial boilers are defined as having an input rating greater than 300,000 Btu/h.

DEFINITION OF BASELINE EQUIPMENT

For Time of Sale and New Construction:
Gas-fired boilers, termed as commercial packaged boilers, manufactured after March 12, 2012 must comply with the standards defined in the Code of Federal Regulations, 10 CFR 431.87.[1100]

Note, for natural draft steam boilers, as IECC 2021, Illinois state energy code, expected to become effective statewide in 2024, exceeds the minimum federal efficiency standards, it was replaced in favor of the more aggressive thermal efficiency values in the table below. For new construction applications where the permitting date is prior to the state's adoption of IECC 2021 it is recommended to use the applicable edition of IECC corresponding to that timeline. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Boiler baseline efficiency standards

Boiler Type	Efficiency[1101]
Hot Water Boiler $\geq$ 300,000 Btu/h and $\leq$ 2,500,000 Btu/h	80% E_T
Hot Water Boiler > 2,500,000 Btu/h and $\leq$10,000,000 Btu/h	82% E_C
Hot Water Boiler >10,000,000 Btu/h	82% E_C
Steam Boiler $\geq$ 300,000 Btu/h and $\leq$ 2,500,000 Btu/h	79% E_T

[1099] Modular boiler arrays have greater combustion efficiencies as compared to traditional steam boilers. This has been verified via a field study done by Nicor Gas ETP. The study covered an industrial manufacturing facility with (10) modular process steam boiler systems; the effective efficiency was found to be in line with the rated manufacturer efficiency of 87%.
[1100] Boilers $\geq$ 300,000 Btu/hr, Code of Federal Regulations, 10 CFR 431.87, Table 1 – Commercial Packaged Boiler Energy Conservation Standards.
[1101] Ibid.

Boiler Type	Efficiency[1101]
Steam Boiler ≥ 2,500,000 Btu/h and ≤10,000,000 Btu/h	79% E_T
Steam Boiler > 10,000,000 Btu/h	79% E_T

where E_T means "thermal efficiency" and E_C means "combustion efficiency" as defined in 10 CFR 431.82.

For early replacement: The efficiency of the existing equipment should be used for the assumed remaining useful life of the equipment and a new baseline equipment as described above for the remainder of the measure life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 25 years.[1102]

For EREP, the remaining useful life of the existing equipment is assumed to be 1/3rd of EUL (25/3) or 8 years.

DEEMED MEASURE COST

The measure cost for this technology is tiered based on the boiler type and combustion efficiencies. As installation costs for the base case and the measure case units are assumed to be the same, labor costs are not specified for this measure.

Incremental and Gross Measure costs for Process Boilers

Boiler Type	Incremental Measure Cost ($/Kbtu)[1103]	Full Measure Cost ($/Kbtu)[1104]
Hot Water Boiler ≥85% E_C and <90% E_C	$2.17	$12.94
Hot Water Boiler ≥90% E_C	$12.17	$22.95
Steam Boiler ≥83% E_C and <85% E_C	$4.35	$19.24
Modular Steam Boiler Arrays (≥85% E_C)[1105]	Custom	

A deferred baseline replacement cost, consistent with the delta between the full measure cost and incremental cost above should be assumed after the remaining useful life of the existing equipment.

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

N/A

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

For first 8 years:

$$\Delta Therms = 8{,}766 * Capacity * UF * \left(\frac{Efficiency_{EE}}{Efficiency_{Exist}} - 1\right) * \frac{1}{100{,}000}$$

For remaining 17 years:

$$\Delta Therms = 8{,}766 * Capacity * UF * \left(\frac{Efficiency_{EE}}{Efficiency_{Base}} - 1\right) * \frac{1}{100{,}000}$$

Where:

8,766	= Annual Operating hours for Process Boilers
	The assumed hours of operation are based on continual plant operation. Variation in plant operating hours is accounted for in the utilization factor. While the boiler may operate during the entire year, it may not be operating at its full rated load.
Capacity	= Nominal heating input capacity boiler size for high-efficiency unit (Btu/hr)
UF	= Utilization Factor
	= Custom or if unknown 41.9%[1106]
$Efficiency_{Exist}$	= Existing boiler efficiency rating,
	= Actual
$Efficiency_{Base}$	= Baseline boiler efficiency rating, dependent on year and boiler type or use actual operating efficiencies for early replacements. See table in "Definition of Baseline Equipment."
$Efficiency_{EE}$	= Efficient boiler efficiency rating for packaged or modular boiler system
	= Actual value, specified to one significant digit (i.e., 95.7%)
100,000	= Constant to convert from Btu to therm

For example, an 800,000 Btu/hr gas-fired process steam boiler with a thermal efficiency rating of 87% is installed replacing a similar sized natural draft steam boiler with baseline efficiency of 79%.

ΔTherms	= 8,766 * 800,000 * 0.419 * (0.870 – 0.790)/0.790 / 100,000
	= 2,976 therms

4.4.55 Commercial Gas Heat Pump

DESCRIPTION

Heat pumps are a class of HVAC equipment that moves heat from cold source to warm sink, moving heat "uphill". Often heat pumps can operate in reverse, using a reversing valve or other means to provide air conditioning (A/C) and space heating with the same product. If heat recovery is employed, the heat pump can also provide service hot water (SHW). Heat pumps generally involve the use of a refrigerant and utilize refrigeration cycles. Gas-fired heat pumps are a subset of heat pumps whose primary input drive energy is a gaseous fuel, instead of an electrically-driven compressor. Gas-fired heat pumps can be separated into two categories, *work-activated* technologies where a delivered fuel drives a prime mover (e.g., internal combustion engine) which supplies work to a refrigerant compressor, and *heat-activated* where the primary energy input to the heat pump cycle is thermal energy, often from fuel combustion, driving a sorption-type or other thermally-driven heat pump cycle.

This measure characterizes the installation of a commercial gas-fired heat pump for the following scenarios: NC, TS, EREP, and RF.

A. New Construction:
    i. The installation of a new commercial heat-activated (e.g., sorption-type) or work-activated (e.g., engine-driven) gas heat pump, certified to ANSI Z21.40.1 or ANSI Z21.40.2 respectively, that meets the criteria laid out in ANSI Z21.40.4 Performance Testing and Rating of Gas-Fired, Air Conditioning and Heat Pump Appliances.
    ii. Note the baseline in this case should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition defined in the Efficient Equipment section.
B. Time of Sale:
    i. The planned installation of a new gas heat pump meeting the efficiency standards laid out below that does not meet the criteria for early replacement as described in section C below.
    ii. Note the baseline in this case is the purchase of new equipment that is similar technology to existing equipment. Where unknown, the baseline should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition. The calculation of savings is dependent on whether an incentive for the installation has been provided by both a gas and electric utility, only an electric utility, or only a gas utility. SHW savings are calculated based on the fuel and efficiency of the existing unit.
C. Early Replacement/Retrofit:
    i. The early removal of functioning electric or gas space heating and/or cooling systems from service, prior to the natural end of life, and replacement with a new high efficiency commercial gas heat pump system.
    ii. Note the baseline in this case is the existing equipment being replaced. The calculation of savings is dependent on whether an incentive for the installation has been provided by both a gas and electric utility, only an electric utility, or only a gas utility. SHW savings are calculated based on the fuel and efficiency of the existing unit.
    iii. Early Replacement determination will be based on meeting the following conditions:
        a. The existing unit is operational when replaced, or
        b. The existing unit requires minor repairs to be operational, defined as costing less than 20% of the new baseline replacement cost (as defined in the Measured Cost section of the relevant equipment).
        c. All other conditions will be considered Time of Sale.

    For the Baseline efficiency of the existing unit being replaced:
        a. Use actual existing efficiency whenever possible.
        b. If the efficiency of the existing unit is unknown, use assumptions based on the Federal minimum standards provided in tables below.

c. If the operational status or repair cost of the existing unit is unknown use time of sale assumptions.

DEFINITION OF EFFICIENT EQUIPMENT

Gaseous fuel heat pumps for space heating/cooling and domestic/service hot water heating. The table below shows the current gas heat pump products in two broad commercial categories – water heating and space heating/cooling. The table additionally lists applicable industry test methods and the primary efficiency metric.

Table 1: Current Gas Heat Pump Products

Equipment			Test Method	Efficiency Metric	
Category	Sector	Type	Industry	Primary Metric	Tested Performance
Water Heating	Commercial	Gas HPWH with or without storage tank	ANSI/ASHRAE 118.1	Coefficient of Performance (COP)	> 1.2 COP
Space Heating & Cooling	Commercial	Gas-fired air-conditioner or heat pump	ANSI Z21.40.4	Coefficient of Performance (COP) for heating / cooling	> 1.2 $COP_{heating}$ or > 1.0 $COP_{cooling}$

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment includes Service Hot Water, Space Heating, and Air-Conditioning.

New Construction:

The 2018 edition of the IECC (effective July 1, 2019 to 12/31/2023) and IECC 2021 (effective statewide as of 1/1/2024) for commercial facilities and is applicable here.

To calculate savings with an electric baseline, the baseline equipment is assumed to be an Air Source Heat Pump meeting the state energy code efficiency level as outlined in **Error! Reference source not found.** (IECC 2018, effective July 1, 2019 to IECC 2021 effective date) and Table 7 (IECC 2021, expected to become effective statewide in 2023) below.

To calculate savings with a chiller/unitary cooling system (**Error! Reference source not found.**, IECC 2018 and Table 8, IECC 2021) and boiler/furnace baseline (**Error! Reference source not found.** and Table 9 for boilers and **Error! Reference source not found.** and Table 10 for warm air furnaces), the baseline equipment is assumed to meet the minimum standard efficiencies as outlined in their respective tables.

To calculate savings with water heater applications, the baseline equipment is assumed to meet the minimum standard efficiencies outlined in **Error! Reference source not found.** (IECC 2018) or Table 11 (IECC 2021).

As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints. If evaluation determines the applicable version of code, given location and timing, isn't an appropriate baseline due to supply constraints, low compliance, or other issues, the previous iteration of code may be used through 2023.

Table 2: IECC 2018 Air-Source Heat Pumps Minimum Efficiency Requirements

TABLE C403.3.2(2)
MINIMUM EFFICIENCY REQUIREMENTS: ELECTRICALLY OPERATED UNITARY AND APPLIED HEAT PUMPS

EQUIPMENT TYPE	SIZE CATEGORY	HEATING SECTION TYPE	SUBCATEGORY OR RATING CONDITION	MINIMUM EFFICIENCY	TEST PROCEDURE[a]

Air cooled absorption, single effect	All capacities	COP (W/W)	≥ 0.600 FL	NA[d]	AHRI 560
Water cooled absorption, single effect	All capacities	COP (W/W)	≥ 0.700 FL	NA[d]	AHRI 560
Absorption double effect, indirect fired	All capacities	COP (W/W)	≥ 1.000 FL	NA[d]	AHRI 560
			≥ 0.150 IPLV.IP		
Absorption double effect, direct fired	All capacities	COP (W/W)	≥ 1.000 FL	NA[d]	AHRI 560
			≥ 1.000 IPLV		

a. Chapter 6 contains a complete specification of the referenced standards, which include test procedures, including the reference year version of the test procedure.
b. The requirements for centrifugal chillers shall be adjusted for nonstandard rating conditions per Section C403.3.2.1 and are applicable only for the range of conditions listed there. The requirements for air-cooled, water-cooled positive displacement and absorption chillers are at standard rating conditions defined in the reference test procedure.
c. Both the full-load and IPLV.IP requirements must be met or exceeded to comply with this standard. When there is a Path B, compliance can be with either Path A or Path B for any application.
d. NA means the requirements are not applicable for Path B, and only Path A can be used for compliance.
e. FL is the full-load performance requirements, and IPLV.IP is for the part-load performance requirements.
f. This table is a replica of ASHRAE 90.1 Table 6.8.1-3 Water-Chilling Packages—Minimum Efficiency Requirements.

Note: Code of Federal Regulations for gas-fired hot water boilers (10 CFR 432I(3)) requires:

<300,000 Btu/hr hot water boilers to be 84% AFUE, and
<300,000 Btu/hr steam boilers to be 82% AFUE
See Table 9 below for all other minimum efficiencies.

	> 210,000 Btu/h	≥ 4,000 Btu/h/gal and ≥ 10 gal	78% E_t $(Q/800 + 110\sqrt{V})SL$, Btu/h	
Hot water supply boilers, gas and oil	≥ 300,000 Btu/h and < 12,500,000 Btu/h	≥ 4,000 Btu/h/gal and < 10 gal	80% E_t	ANSI Z21.10.3
Hot water supply boilers, gas	≥ 300,000 Btu/h and < 12,500,000 Btu/h	≥ 4,000 Btu/h/gal and ≥ 10 gal	80% E_t $(Q/800 + 110\sqrt{V})SL$, Btu/h	
Hot water supply boilers, oil	> 300,000 Btu/h and < 12,500,000 Btu/h	> 4,000 Btu/h/gal and > 10 gal	78% E_t $(Q/800 + 110\sqrt{V})SL$, Btu/h	

Time of Sale: The baseline for this measure is a new replacement unit of the same system type as the existing unit, meeting the minimum efficiencies provided above.

Early Replacement / Retrofit: The baseline for this measure is the efficiency of the *existing* heating, cooling, and hot water equipment for the assumed remaining useful life of the existing unit, and a new baseline heating and cooling system for the remainder of the measure life (as provided in tables above).

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life of the gas heat pump is assumed to be 15 years for a natural gas heat pump[1107].

For early replacement, the remaining life of existing equipment is assumed to be 6 years for an air-source heat pump and Central A/C, 6 years for a furnace, and 8 years for boilers and ground source heat pumps.[1108]

DEEMED MEASURE COST

New Construction and Time of Sale: Incremental costs of the gas heat pump should be used. This would be the actual installed cost of the heat pump equipment as well as system commissioning costs, minus the assumed installation cost of the baseline equipment.

Early Replacement: The actual installed cost of the gas heat pump should be used. The assumed deferred cost of replacing existing equipment with a new baseline is 1/3 of the incremental cost. This future cost should be discounted to present value using the nominal societal discount rate.

The incremental cost of gas heat pump over various replacement equipment is shown in **Table 7**[1109].

Table 7: Incremental Cost of Commercial Gas Heat Pump

Incremental Cost ($/ton)		
Replaced Technologies	**Installed Cost ($/ton)**	**Incremental GHP Cost ($/ton)**
Rooftop Air Source Heat Pump	$1,813	$1,987
Ground Source Heat Pump	$5,781	-$1,981
Electric Boiler	$250	$3,550
Natural Gas Furnace	$92	$3,709
Natural Gas Boiler	$594	$3,206
Air-cooled Electric Chiller	$988	$2,813
Water-cooled Electric Chiller	$550	$3,250
Gas-fired Water Heater	$384	$3,416
Electric-resistance Water Heater	$772	$3,028
Gas Heat Pump	$3,800	

Guide to read incremental cost:

Example 1: for a gas boiler and air-cooled electric chiller being replaced with a gas heat pump, the incremental cost will be (Cost of GHP) – (Cost of Natural Gas Boiler + Air-Cooled Electric Chiller) = $3,800 – ($594 + $988) = $2,218.

Example 2: for a gas boiler and gas-fired water heater being replaced with a gas heat pump, the incremental cost will be Cost of GHP – (Cost of Natural Gas Boiler + Gas Fired Water Heater) = $3,800 – ($594+$384) = $2,822.

LOADSHAPE

Depending on the baseline conditions, the appropriate loadshapes will be a combination of some, but not all, of the loadshapes below. Note for the purpose of cost-effectiveness screening for a fuel switching scenario, the cooling therm increase, and heating therm decrease should be calculated separately such as the appropriate loadshape (i.e.,

[1107] U.S. Energy Information Administration | Assumptions to the Annual Energy Outlook 2021: Commercial Demand Module: https://www.eia.gov/outlooks/aeo/assumptions/pdf/commercial.pdf
[1108] Assumed to be one third of effective useful life of replaced equipment.
[1109] U.S. Energy Information Administration (EIA), Updated Buildings Sector Appliance and Equipment Costs and Efficiencies, March 2023: https://www.eia.gov/analysis/studies/buildings/equipcosts/pdf/full.pdf

Loadshape C04 – Commercial Electric Heating and Loadshape C03 – Commercial Cooling, respectively) can be applied.

Loadshape C02 – Commercial Electric SHW

Loadshape C03 – Commercial Cooling

Loadshape C04 – Commercial Electric Heating (if replacing building with no existing cooling)

Loadshape C05 – Commercial Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits. The second represents the average savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial Cooling (during system peak hour)

= 91.3%[1110]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial Cooling (average during peak period)

= 47.8%[1111]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS AND FOSSIL FUEL SAVINGS

Non-Fuel Switch Measures:

$$\Delta\text{therms} = \Delta therms_{SPACE} + \Delta therms_{SHW}$$

Space Heating Savings

$$\Delta\text{therms}_{SPACE} = EFLH * Capacity * ((Efficiency_{EE} - Efficiency_{Base}) / Efficiency_{Base}) / 100{,}000$$

Where:

EFLH = Equivalent Full Load Hours for heating in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use

Capacity = Nominal Heating Input Capacity Size (Btu/hr) for efficient unit not existing unit

= custom gas-fired heat pump input capacity (Btu/hr)

$Efficiency_{Base}$ = Baseline Efficiency Rating, dependant on year and boiler type. See Table 4 above

$Efficiency_{EE}$ = Rated Commerical Gas Heat Pump space heating efficiency, expressed as a fuel-input only COP_{Gas}, for the nominal capacity rating condition

[1110] Values taken from established TRM references in section 4.4.44 and based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1111] Values taken from established TRM references in section 4.4.44 and based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm M-F, June through August) is divided by the maximum AC load during the year.

Hot water boiler baseline:

Hot Water Boiler Capacity (Btu/hr)	Efficiency
Hot Water < 300,000 [1112]	84% AFUE
300,000 ≤ Hot Water ≤ 2,500,000 [1113]	80% E_T
2,500,000 < Hot Water [1114]	82% E_C

For example, a 150,000 BTU/hr water boiler meeting COP_{Gas} 1.4 is installed in Rockford at a high-rise office building in the year 2022:

ΔTherms = 2,089 * 150,000 * (1.4 - 0.840) / 0.840) / 100,000 Btu/Therm
= 2,089.0 therms

Service Hot Water Savings:

$$\Delta Therms_{SHW} = \frac{(T_{out} - T_{in}) * HotWaterUse_{Gallon} * \gamma Water * 1.0 * \left(\frac{1}{TE_{gasbase}} - \frac{1}{COP_{Eff}}\right)}{100{,}000}$$

Where:

T_{OUT} = Tank temperature
= 140°F

T_{IN} = Incoming water temperature from well or municipal system
= 50.7°F [1115]

$HotWaterUse_{Gallon}$
= Estimated annual hot water consumption (gallons)
= Actual, if possible to provide reasonable custom estimate. If not, two methodologies are provided to develop an estimate:

1. Consumption per usable storage tank capacity = Capacity * (Consumption/Cap)

Where:

Capacity = Usable capacity of hot water storage tank in gallons
= Actual

Consumption/Cap = Estimate of consumption per gallon of usable tank capacity, based on building type:[1116]

Building Type[1117]	Consumption/Cap
Convenience	528
Education	568
Grocery	528

[1112] Code of Federal Regulations, effective January 15, 2021 (10 CFR 432(e)(3)).
[1113] Thermal Efficiency. Code of Federal Regulations, effective March 2, 2012 (10 CFR 431.87).
[1114] Combustion Efficiency. Code of Federal Regulations, effective March 2, 2012 (10 CFR 431.87).
[1115] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.
[1116] Methodology based on Cadmus analysis. Annual hot water usage in gallons based on CBECS (2012) and RECS (2009) consumption data of East North Central (removed outliers of 1,000 kBtuh or less) to calculate hot water usage. Annual hot water gallons per tank size gallons based on the tank sizing methodology found in ASHRAE 2011 HVAC Applications. Chapter 50 Service Water Heating. Demand assumptions (gallons per day) for each building type based on ASHRAE Chapter 50 and to LBNL White Paper. LBL-37398 Technology Data Characterizing Water Heating in Commercial Buildings: Application to End Use Forecasting. Assumes hot water heater efficiency of 80%.
[1117] According to CBECS 2012 "Lodging" buildings include Dormitories, Hotels, Motel or Inns and other Lodging and "Nursing" buildings include Assisted Living and Nursing Homes.

Building Type[1117]	Consumption/Cap
Health	788
Large Office	511
Large Retail	528
Lodging	715
Other Commercial	341
Restaurant	622
Small Office	511
Small Retail	528
Warehouse	341
Nursing	672
Multi-Family	894

2. Consumption per unit area by building type = (Area / 1000) * Consumption/1,000ft^2

Where:

Area = Area in ft^2 that is served by SHW boiler
= Actual

Consumption/1,000ft^2 = Estimate of SHW consumption per 1,000ft^2 based on building type:[1118]

Building Type[1119]	Consumption/1,000ft^2
Convenience	4,594
Education	7,285
Grocery	697
Health	24,540
Large Office	1,818
Large Retail	1,354
Lodging	29,548
Other Commercial	3,941
Restaurant	44,439
Small Office	1,540
Small Retail	6,111
Warehouse	1,239
Nursing	30,503
Multi-Family	15,434

γWater = Specific weight capacity of water (lb/gal) = 8.33 lbs/gal

1 = Specific heat of water (Btu/lb·°F)[1120]

100,000 = Converts Btu to Therms

$TE_{gasbase}$ = Rated efficiency of baseline water heater (expressed as Uniform Energy Factor (UEF) or Thermal Efficiency as provided below).

[1118] Methodology based on Cadmus analysis. Annual hot water usage in gallons based on CBECS (2012) and RECS (2009) consumption data of East North Central (removed outliers of 1,000 kBtuh or less) to calculate hot water usage. Annual hot water gallons per tank size gallons based on the tank sizing methodology found in ASHRAE 2011 HVAC Applications. Chapter 50 Service Water Heating. Demand assumptions (gallons per day) for each building type based on ASHRAE Chapter 50 and to LBNL White Paper. LBL-37398 Technology Data Characterizing Water Heating in Commercial Buildings: Application to End Use Forecasting. Assumes hot water heater efficiency of 80%.

[1119] According to CBECS 2012 "Lodging" buildings include Dormitories, Hotels, Motel or Inns and other Lodging and "Nursing" buildings include Assisted Living and Nursing Homes.

[1120] Specific heat is the amount of heat required to change the temperature of a mass by one degree.

COP_{Eff} = Rated efficiency of the commercial gas heat pump as certified expressed as Uniform Energy Factor (UEF) or Coefficient of Performance as provided below.

Note the same draw pattern (very small, low, medium, and high draw) should be used for both baseline and efficient units.

Equipment Type	Sub-Category	Draw Pattern	Federal Standard – Uniform Energy Factor or Thermal Efficiency[1121]
Residential-duty Commercial High-Capacity Storage Gas-Fired Storage Water Heaters >75,000 Btu/h	≤120 gallon tanks	Very small	UEF = 0.2674 – (0.0009 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5362 – (0.0012 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6002 – (0.0011 * Rated Storage Volume in Gallons)
		High	UEF = 0.6597 – (0.0009 * Rated Storage Volume in Gallons)
Commercial Gas Storage Water Heaters >75,000 Btu/h	>120 gallon tanks	All	80% $E_{thermal}$, Standby Losses = (Q /800 + 110√Rated Storage Volume in Gallons)
Commercial Gas Storage Water Heaters >155,000 Btu/h		All	
Commercial Gas Instantaneous Water Heaters >200,000 Btu/h	<10 gallon	All	80% $E_{thermal}$
	≥10 gallon	All	78% $E_{thermal}$

Draw patterns are based on first hour rating (gallons) for storage tanks and maximum flow (GPM) for instantaneous as shown below:[1122]

Storage Water Heater Draw Pattern	
Draw Pattern	**First Hour Rating (gallons)**
Very Small	≥ 0 and < 18
Low	≥ 18 and < 51
Medium	≥ 51 and < 75
High	≥ 75

Instantaneous Water Heater Draw Pattern	
Draw Pattern	**Max GPM**
Very Small	≥ 0 and < 1.7
Low	≥ 1.7 and < 2.8
Medium	≥ 2.8 and < 4

For example, for a 200,000 Btu/h, 150 gallon, GHP with a COP = 1.4 installed in a 1500 ft^2 restaurant:

ΔTherms = ((140 – 50.7) * ((1,500/1,000) * 44,439) * 8.33 * 0.975 * (1/0.8 - 1/1.4))/100,000

= 259.0 Therms

[1121] All Residential sized Federal Standards are from DOE Standard 10 CFR 430, Residential-Duty and Commercial Federal Standard are from DOE Standard 10 CFR 431.

[1122] Definitions provided in 10 CFR 430, Subpart B, Appendix E, Section 5.4.1.

Fuel Switch Measures:

Fuel switching measures must produce positive total annual fuel savings (i.e., reduction in Btus) in order to qualify. This is determined as follows (note for early replacement measures the lifetime savings should be calculated by calculating savings for the remaining useful life of the existing equipment and for the remaining measure life):

SiteEnergySavings (MMBTUs) $= (ElectricHeatReplaced - GHPEnergyConsumed_{Heat}) + (ElectricCoolingReplaced - GHPEnergyConsumed_{Cool}) + (ElectricWaterHeatReplaced - GHPEnergyConsumed_{SHW})$

If Energy Savings calculated above is positive, the measure is eligible.

Electric Space Heating Replaced with Natural Gas Heat Pump

ElectricHeatReplaced [MMBTU] $= (kBtu/hr_{heat} * EFLH_{heat} * (1/COP_{base})) / 1{,}000$

GHPEnergyConsumed$_{Heat}$ [MMBTU] $= ((kBtu/hr_{heat} * EFLH_{heat} * (1/COPP_{GH})) / 1{,}000$

Where:

kBtu/hr$_{heat}$ = capacity of the heating equipment in kBtu per hour (1 ton of heating capacity equals 12 kBtu/hr).

COP$_{base}$ = Coefficient of performance of the baseline equipment, or thermal efficiency if applicable, at nominal condition

= based on the applicable Code on the date of equipment purchase (if unknown assume current Code). If rating is HSPF, COP = HSPF / 3.413

EFLH$_{Heat}$ = Heating Equivalent Full Load Hours
= Dependent on building type and Existing Buildings or New Construction, provided in section 4.4 HVAC End Use

COP$_{GHP}$ = Coefficient of performance of the GHP equipment at nominal condition
= Actual installed

Electric Cooling Replaced with Natural Gas Heat Pump

ElectricCoolingReplaced [MMBTU] $= (kBtu/hr_{cool} * EFLH_{cool} * (1 * 3.412/EER_{base})) / 1{,}000$

GHPEnergy Consumed$_{cool}$ [MMBTU] $= ((kBtu/hr_{cool} * EFLH_{cool} * (1/COP_{GHP})) / 1{,}000)$

kBtu/hr$_{cool}$ = capacity of the cooling equipment in kBtu per hour (1 ton of cooling capacity equals 12 kBtu/hr).

EER$_{base}$ = Energy Efficiency Ratio of the baseline equipment at nominal condition

EFLH$_{cool}$ = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

COP$_{GHP}$ = Coefficient of performance of the GHP equipment at nominal condition
= Actual installed

Electric Water Heating Replaced with Natural Gas Heat Pump

ElectricWaterHeatReplaced [MMBTU] $=((T_{out} - T_{in}) * HotWaterUse_{gallon} * \gamma Water * 1.0 * (1/TE_{elecbase}))/ 1{,}000{,}000$

GHPEnergyConsumed$_{SHW}$ [MMBTU] $=(Tt_{ou} - T_{in}) * HotWaterUse_{gallon} * \gamma Water * 1.0 * (1/COP_{GHP}) / 1{,}000{,}000$

**See previous nonfuel switch section for most descriptions

$TE_{elecbase}$ = Rated efficiency of baseline water heater expressed as Uniform Energy Factor (UEF) or Thermal Efficiency (TE) or Coefficient of Performance (COP), if not provided for resistance-type electric water heating assume $TE_{elec,base}$ = 0.98

COP_{GHP} = Coefficient of performance of the GHP equipment
= Actual installed

Total Therm Savings = SiteEnergySavings * 10

Example:

A 3,000-squarefoot building with a 120 kBtu/hr output gas heat pump system replacing existing baseline equipment with COP of 1.3 in heating, cooling, and water heating in a Chicagoland public elementary school. The baseline equipment being replaced are all electric heating, cooling, and service hot water heater. Measure Type is EREP/RF

Baseline equipment efficiency: electric baseboard heating – 1.0 COP; electric air source cooling – 10.8 EER. Electric service hot water heater – 0.98 TE.

Heating Site MMBTU Savings = ElectricHeatReplaced - $GHPEnergyConsumed_{Heat}$

ElectricHeatReplaced [MMBTU] = $(kBtu/hr_{heat} * EFLH_{heat} * (1/COP_{base}))$ / 1,000

= $(120 * 1603 * (1/2.25))$ /1,000

= $192.4\ MMBtu$

$GHPEnergyConsumed_{Heat}$ [MMBTU] = $((kBtu/hr_{heat} * EFLH_{heat} * (1/COP_{GHP}))$ / 1000)

= $(120 * 1603 * 1/1.3)/1000$

= $148.0\ MMBtu$

Cooling Site MMBTU Savings = $ElectricCoolingReplaced - GHPEnergy\ Consumed_{cool}$

ElectricCoolingReplaced [MMBTU] = $(kBtu/hr_{cool} * EFLH_{cool} * (1 * 3.412/EER_{base}))$ / 1,000

= $(120 * 837 * (1 * 3.412/10.8))$ /1,000

= $31.7\ MMBtu$

$GHPEnergy\ Consumed_{cool}$ [MMBTU] = $((kBtu/hr_{cool} * EFLH_{cool} * (1/COP_{GHP}))$ / 1000)

= $(120 * 837 * 1/1.3)$ /1000

= $77.3\ MMBtu$

Service Hot Water Heater Site MMBTU Savings = $ElectricWaterHeatReplaced - GHPEnergyConsumed_{SHW}$

ElectricWaterHeatReplaced [MMBTU] = $((T_{out} - T_{in}) * HotWaterUse_{gallon} * \gamma Water * 1.0 * (1/TE_{elecbase}))$ / 1,000,000

= $((140 - 50.7) * (7285 * 3) * 8.33 * 1 * (1/0.98))$ / 1,000,000

= $16.6 MMBtu$

$GHPEnergyConsumed_{SHW}$ [$MMBTU_{source}$] = $((T_{out}-T_{in}) * HotWaterUse_{gallon} * \gamma Water * 1.0 * (1/COP_{GHP})$ / 1,000,000)

= (((140 - 50.7) * (7285*3) * 8.33 * 1.0 * (1/1.3))/1,000,000)

= 12.5 MMBtu

Example continued:

GHPEnergyConsumed$_{SHW}$ [MMBTU$_{source}$] = $((T_{out} - T_{in}) * HotWaterUse_{gallon} * \gamma Water * 1.0 * (1/COP_{GHP}) / 1{,}000{,}000)$

= $(((140 - 50.7) * (7285 * 3) * 8.33 * 1.0 * (1/1.3))/1{,}000{,}000)$

= 12.5 $MMBtu$

Total Site MMBTU Savings = $(194.2 - 148.0) + (31.7 - 77.3) + (16.6 - 12.5)$

= 4.7 $MMBtu$

SUMMER COINCIDENT PEAK DEMAND SAVINGS

New Construction / Time of Sale:

$$\Delta kW = (kBtu/hr * (1/EER_{base})) * CF$$

Early Replacement / Retrofit:

$$\Delta kW = (kBtu/hr * (1/EER_{exist})) * CF$$

Where:

EER_{base} = Energy Efficiency Ratio of the baseline equipment

EER_{exist} = Energy Efficiency Ratio of the existing equipment

= Actual, or assume Code base in place at the original time of existing unit installation

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1123]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1124]

For example, a 120 kBtu/hr electric air source cooling with a 10.8 EER replaced with a gas heat pump in Chicago would save:

ΔkW_{SSP} = (120 * (1 / 10.8)) * 0.913

= 10.14 kW

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A. The installed cost of gas heat pump includes O&M agreement.

[1123] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1124] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from electric to gas.

For the purposes of forecasting load reductions due to fuel switch HP projects; changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure. For Early Replacement measures, the efficiency terms of the existing unit should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 6 years for furnace, 8 years for boilers or GSHP, 15 years for electric resistance), and the efficiency terms for a new baseline unit should be used for the remaining years of the measure.

ΔTherms = $[Increased\ Consumption]$

ΔTherms = $-\ (Therms_{SPACE}\ +\ Therms_{SHW}\ +\ Therms_{Cool})$

$Therms_{SPACE}$ = $((kBtu/hr_{heat})\ *\ 1/COP_{GHP}\ *\ EFLH_{heat})*\ 1000/\ 100{,}000$

$Therms_{SHW}$ = $((T_{out}-T_{in})\ *\ HotWaterUse_{gallon}*\ \gamma Water\ *1\ *\ (1/COP_{GHP}))/\ 100{,}000$

$Therms_{Cool}$ = $((kBtu/hr_{cool})\ *\ 1/COP_{GHP}\ *\ EFLH_{cool})\ *\ 1{,}000/100{,}000$

ΔkWh = $[Replaced\ Consumption]$

ΔkWh = $(kWh_{SPACE}\ +\ kWh_{SHW}\ +\ kWh_{Cool})$

kWh_{SPACE} = $(kBtu/hr_{heat})/3.412\ *\ 1/COP_{base}\ *\ EFLH_{heat}$

kWh_{SHW} = $((T_{out}-T_{in})\ *\ HotWaterUse_{gallon}*\ \gamma Water\ *0.975\ *\ (1/TE_{elecbase}))/\ 3413$

kWh_{Cool} = $(kBtu/hr_{cool})\ *\ (1/EER_{base})\ *\ EFLH_{cool}$

MEASURE CODE: CI-HVC-GFHP-V05-260101

REVIEW DEADLINE: 1/1/2027

4.4.56 Commercial Duct Sealing

DESCRIPTION

This measure was developed to reduce the heating and cooling losses from ducts running through un-conditioned spaces, including, but not limited to: unheated/uncooled attics, basements or crawlspaces; or the outdoors. To the extent that the duct runs through a conditioned space, such as occupied rooms, between conditioned building floors, or semi-heated or semi-cooled spaces, this measure is not applicable as it is assumed that all heating or cooling losses from the duct perform beneficial heating or cooling to the conditioned space. This assumption ignores the potential overheating and overcooling of the conditioned space, which energy waste is hereby deemed to be negligible.[1125]

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is installing duct wrap or other insulation to a length of HVAC ductwork. If applied to ductwork that currently, or in the future may transmit cooling air, the insulation must be wrapped with an impermeable vapor barrier.

The efficient duct air sealing case is installing elastomeric sealant externally to cracks and holes in ductwork that completely and permanently seals the ductwork from air leakage. The elastomeric material must remain flexible and adhere to the ductwork during the measure lifetime and to withstand significant swings in ductwork temperature without losing its sealing capability.

DEFINITION OF BASELINE EQUIPMENT

Baseline equipment is an uninsulated and/or un-sealed duct located within an un-conditioned space. If a duct has previously been insulated but a significant portion of the insulation has deteriorated or fallen off, the program shall verify the duct insulation condition and determine whether the duct can be considered “un-insulated” for purposes of applying for an incentive.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 20 years.[1126]

DEEMED MEASURE COST

The actual installation cost should be used if known. If unknown, the measure cost for duct insulation, including material and installation, is assumed to be $8.00 per square foot[1127] and for duct crack sealing, including materials and installation, is assumed to be $15.00 per linear foot.[1128]

LOADSHAPE

Loadshape C01 – Commercial Electric Cooling

Loadshape C03 – Commercial Cooling

Loadshape C04 – Commercial Electric Heating

Loadshape C05 – Commercial Electric Heating and Cooling

[1125] It is recommended that additional analyses be considered using custom analysis to determine the extent of overheating or overcooling from uninsulated or unsealed ductwork running through conditioned spaces.
[1126] Measure Life Report, Residential and Commercial/Industrial Lighting and HVAC Measures, GDS Associates, June 2007.
[1127] Engineering estimate provided by John Johnson.
[1128] Engineering estimate provided by John Johnson.

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1129]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1130]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Where available, savings from duct Insulaton measures should be determined through a custom analysis. When that is not feasible for the program, the following engineering algorithms can be used.

$$\Delta kWh = \Delta kWh_cooling + \Delta kWh_heatingElectric + \Delta kWh_heatingGas$$

Where:

ΔkWh_cooling = If building is cooled, reduction in annual cooling requirement due to duct insulation

$$= ((1 / R_DuctExist - 1 / R_DuctEfficient) * A_Duct + 1.08 * CFM_Saved * EFLHCool * (Avg_Clg_OAT - Avg_Duct_Clg_SAT)) / 1000 / \eta Cool * \%Cool$$

Where:

$R_Duct_{Efficient}$ = Average R-value of proposed duct assembly after installation of additional insulation

= Actual

R_Duct_{Exist} = Average R-value value of existing duct assembly, including any existing insulation

= if duct is uninsulated, the average R-value deemed to be 0.8 hr-sf-F/BTU[1131]

A_Duct = Net area of duct proposed to be insulated (ft^2)

= Actual

1.08 = Specific heat of air x density of inlet air @ 70F x 60 min/hr in BTU

CFM_Saved = Quantity of duct leakage saved by application of crack sealant to previously unsealed ductwork

[1129] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1130] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1131] ASHRAE. Inside duct air film assumed to be <0.1 hr-sf-F/BTU; Outside of duct assumed to be in still air with air film R-value of 0.79 hr-sf-F/BTU,

= CFM/Ft for average crack width from table below[1132], adjusted for actual duct internal pressure[1133] * Length of Crack (Ft.)

Average Crack Width (Inches)	CFM Air Leakage per Foot of Crack @ 0.3" w.c. duct
0.00	0 CFM
0.05	7 CFM
0.10	13 CFM
0.15 (Default if Unknown)	20 CFM
0.20	26 CFM
0.25	33 CFM
0.30	39 CFM
0.35	46 CFM
0.40	52 CFM
0.45	59 CFM
0.50	65 CFM
Unknown	20 CFM

$EFLH_{Cool}$ = Equivalent Full Load Hours for cooling in Existing Buildings are provided in section 4.4 HVAC End Use

Avg_Clg_OAT = Deemed average ambient air temperature over the cooling season in the building space through which the HVAC duct runs, based on climate zone:[1134]

Climate Zone	Cooling Season Avg OA DBT
1 - Rockford	71.3 degF
2 - Chicago	73.7 degF
3 - Springfield	70.7 degF
4 - Belleville	76.3 degF
5 - Marion	69.0 degF

Avg_Duct_Clg_SAT = 60 degF.[1135]

[1132] ASHRAE Fundamentals (2017), Page 16.28, Fig 14. Elevator door CFM assumed to apply to low-rise commercial buildings. Straight line regression analysis was used by ASHRAE: CFM values from 0.0" to 0.2" crack width for personnel doors; and CFM values from 0.0" to 0.3" crack width for elevator doors. The same straight line regression formula is assumed to apply to larger crack widths up to 0.5.

[1133] ASHRAE Fundamentals (2017), Page 16.28, Fig. 14: "For other dP, Multiply Leakage Rate by (dP/0.3)^0.55" .

[1134] BinMaker Pro weather data, based on average outdoor air temperatures over the hottest 5 calendar months. Outdoor average temperatures is assumed to be equivalent to the average temperatures of typical duct locations in: attics, basements, crawl spaces and outdoors. Additional research is recommended to verify actual average ambient temperatures in these areas; additional inputs may be recommended to identify the actual space type of the duct and create a lookup table based on space type and climate zone.

[1135] Engineering estimate by John Johnson – Leidos, based on estimate of average supply air temperature, both for continuous fan operation scenarios and automatic on/off fan operation scenarios. Additional research is recommended to verify actual average duct cooling supply temperatures; additional inputs may be recommended to identify HVAC fan control modes and create a lookup table based on fan control mode type and climate zone.

24 = Converts days to hours

1000 = Converts Btu to kBtu

ηCool = Efficiency of cooling system * Distribution efficiency. Actual, if known and assume 95% distribution efficiency. Alternatively, use IECC 2012 as a default source if equipment type is known, or as deemed from table below[1136]

Space Cooling	Deemed Cooling EER2	Deemed Cooling SEER2
No Cooling	N/A	N/A
Unknown Cooling Source	10.2	11.1

%Cool = Percent of building ***where duct insulation is to be installed*** that is cooled

= Actual %, if known, or, If actual % unknown, use following deemed values:

Is Space Being Insulated Cooled?	Deemed %Cool, if actual % is unknown
Yes	100%
No	0%

For example, insulating an uninsulated 300 ft^2 duct and sealing 473 cfm leakage for an Assembly Building Type in Rockford with unknown cooling system: R_Duct_{Exist} = 0.8; $R_Duct_{Efficient}$ = 12.8; A_Duct = 300; CFM_Saved = 473; $EFLH_{Cool}$ = 725; Avg_Clg_OAT = 71.3; Avg_Duct_Clg_SAT = 60; ηCool = 13.0; %Cool = 100%

ΔkWh_cooling = ((1 / 0.8 - 1 / 12.8) * 300 + 1.08 * 473) * 725 * (71.3 - 60) / 1000 / 13.0 * 100%

= 543 kWh

ΔkWh_heatingElectric = If electric heat (resistance or heat pump), reduction in annual electric heating due to wall and/or foundation insulation

$$= [(1 / R_DuctExist - 1 / R_DuctEfficient) * A_Duct + 1.08 * CFM_Saved] * EFLHHeat * (Avg_Duct_Htg_SAT - Avg_Htg_OAT) / \eta Heat / 3412 * \%ElectricHeat$$

Where:

$EFLH_{Heat}$ = Equivalent Full Load Hours for heating in Existing Buildings are provided in section 4.4 HVAC End Use

Avg_Htg_OAT = Deemed average ambient air temperature over the cooling season in the building space through which the HVAC duct runs, based on climate zone:[1137]

1136 Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER and EER values converted to SEER2/EER2 by multiplying by 0.95.

1137 BinMaker Pro weather data, based on average outdoor air temperatures over the hottest 5 calendar months. Outdoor average temperatures is assumed to be equivalent to the average temperatures of typical duct locations in: attics, basements,

Climate Zone	Heating Season Avg OA DBT
1 - Rockford	29.4 degF
2 - Chicago	34.2 degF
3 - Springfield	27.4 degF
4 - Belleville	38.4 degF
5 - Marion	31.4 degF

Avg_Duct_ Htg _SAT = 85 degF.[1138]

ηHeat = Efficiency of heating system * distribution efficiency, as deemed from table below

System Type	HSPF2 Estimate	ηHeat (Effective COP Estimate) (HSPF2/3.413)*0.95 (distribution efficiency)
Heat Pump	7.37[1139]	2.05
Resistance	N/A	1

3412 = Converts Btu to kWh

%ElectricHeat = Percent of building ***where duct insulation is to be installed*** that is electrically heated

= Actual %, if known, or, If actual % unknown, use following deemed values:

Is Space Being Insulated Electrically Heated?	Deemed %ElectricHeat, if actual % is unknown
Yes	100%
No	0%

For example, insulating an uninsulated 300 ft^2 duct and sealing 473 cfm leakage for an Assembly Building Type in Rockford with electric resistance heating system: R_Duct_{Exist} = 0.8; $R_Duct_{Efficient}$ = 12.8; A_Duct = 300; CFM_Saved = 473; $EFLH_{Heat}$ = 1787; Avg_Htg_OAT = 29.4; Avg_Duct_Htg_SAT = 85; ηHeat = 1.0; %Electric Heat = 100%

ΔkWh_heatingElectric = ((1 / 0.8 – 1 / 12.8) * 300 + 1.08 * 473) * 1787 * (85 - 29.4) / 3412 / 1.0 * 100%

= 25,113 kWh

crawl spaces and outdoors. Additional research is recommended to verify actual average ambient temperatures in these areas; additional inputs may be recommended to identify the actual space type of the duct and create a lookup table based on space type and climate zone.

[1138] Engineering estimate by John Johnson – Leidos, based on estimate of average supply air temperature, both for continuous fan operation scenarios and automatic on/off fan operation scenarios. Additional research is recommended to verify actual average duct heating supply temperatures; additional inputs may be recommended to identify HVAC fan control modes and create a lookup table based on fan control mode type and climate zone.

[1139] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note HSPF value converted to HSPF2 by multiplying by 0.85.

ΔkWh_heatingGas = If gas furnace or boiler heat, kWh savings for reduction in combustion fan run time

$= \Delta Therms * Fe * 29.3$

Where:

ΔTherms = Annual therms of gas space heating saved, as determined below

F_e = Furnace or boiler combustion fan energy consumption as a percentage of annual fuel consumption

= 7.7%

29.3 = conversion of therms to kWh (= 100000 / 3412)

Other variables as defined above

For example, if: ΔTherms = 1072; F_e = 7.7%, then:

ΔkWh_heatingGas = 1072 * 7.7% * 29.3

= 2419 kWh

For example, based on the above calculations with electric resistance heat, total annual kWh savings =

Total Annual kWh Savings = 543 + 25,113 + 0

= 25,657 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh_cooling}{EFLH_Cooling} * CF$$

Where:

ΔkWh_cooling = Annual kWh saving in cooling energy use, as determined above

EFLH_cooling = Equivalent Full Load Hours for cooling in Existing Buildings are provided in section 4.4 HVAC End Use

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1140]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1141]

[1140] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1141] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

For example based on example above: ΔkWh_cooling = 543; EFLH_Cooling = 725; CF = 0.478; then:

Summer Coincidcent Peak savings = 543 / 725 * 0.478
= 0.36 kW

FOSSIL FUEL SAVINGS

If Natural Gas heating:

ΔTherms

$$= [(1 / R_DuctExist - 1 / R_DuctEfficient) * A_Duct + 1.08 * CFM_Saved] * EFLHHeat * (Avg_Duct_Htg_SAT - Avg_Htg_OAT) / \eta Heat / 100{,}000 * \%GasHeat$$

Where:

ηHeat = Efficiency of heating system, including distribution losses
= Actual, if unknown assume 0.821.[1142]

%GasHeat = Percent of space being retrofitted with insulation that is heated using gas
= Actual %, if known, or, If actual % unknown, use following deemed values:

Is Space Being Insulated Heated with Gas?	Deemed %GasHeat, if actual % is unknown
Yes	100%
No	0%

Other variables as defined above

For example, insulating an uninsulated 300 ft^2 duct and sealing 473 cfm leakage for an Assembly Building Type in Rockford with unknown gas heating system: R_ExistWall = 0.8; R_NewWall = 12.8; A_Duct = 300; CFM_Saved = 473; $EFLH_{Heat}$ = 1787; Avg_ Htg _OAT = 29.4; Avg_Duct_ Htg _SAT = 85; ηHeat = 0.8; %GasHeat = 100%; then

Annual Therm Savings = ((1 / 0.8 - 1 / 12.8) * 300 + 1.08 * 473) * 1787 * (85 - 31.4) / 0.8 / 100,000 * 100%
= 1033 therms

MEASURE CODE: CI-HVC-DSEAL-V03-260101

REVIEW DEADLINE: 1/1/2029

1142
Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

4.4.57 Condensate Recovery System

DESCRIPTION

This measure is applied to steam fossil-fuel fired boilers where partial or no condensate is returned. As more condensate is returned into the boiler system, less make-up water is required, saving fossil-fuel, make-up water chemical, and treatment cost[1143]. Less condensate discharged into the sewer also means reduced disposal costs and reduction in energy losses due to energy blowdown[1144]. The measure is applicable to commercial applications, commercial HVAC including multifamily buildings, low pressure applications, medium pressure industrial applications, and high-pressure industrial applications.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as functional steam system that increase the return of condensate in comparison to the baseline case. New systems are not eligible for this measure.

DEFINITION OF BASELINE EQUIPMENT

Baseline is an existing steam boiler system where minimal or no condensate is returned.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years[1145].

DEEMED MEASURE COST

If known, the actual material and labor cost of installation should be used. If unknown, the average measure cost per GPM of condensate returned is $4,861[1146]. This cost includes material and labor for installing condensate recovery systems (storage tanks, pipes and pumps).

LOADSHAPE

Loadshape C35 – Industrial Process
Loadshape C36 – HVAC Pump motor (heating)

COINCIDENCE FACTOR

For process boiler systems, the summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

0 for space heating boiler systems.

10,000	15.00	10	1/2
71		20	1/2

[1147] Condensate pumps are rated in square feet EDR. To convert boiler rating to square feet EDR use the following conversion factors:
Multiply boiler horsepower (BHP) by 140 to get square feet EDR
Divide Btu/h by 240 to get square feet EDR
Multiply lbs of steam per hour by 4 to get square feet EDR
A boiler can put out half a gallon per 1000 sq ft EDR per minute. Size the pump capacity for twice to three times the return rate. Then assign a motor HP based on the system's pressure requirement.

0.746 = Conversion factor from horsepower to kW (kW/hp)

$\frac{LF}{\eta_{motor}}$ = Combined as a single factor since efficiency is a function of load

Where:

LF = Load Factor; Ratio of the peak running load to the nameplate rating of the motor

= Actual, or if unknown 0.65[1149]

η_{motor} = Motor efficiency at pump operating conditions

= Actual

HOURS = Annual operating hours of the pump

For space heating

= Operating hours of heating system

For other processes

= Actual. If unknown:

Shift	Hours
Single shift (8/5)	1,976 hours 7 AM – 3 PM, weekdays, minus some holidays and scheduled down time
2-shift (16/5)	3,952 hours 7AM – 11 PM, weekdays, minus some holidays and scheduled down time
3-shift (24/5)	5,928 hours 24 hours per day, weekdays,
4-shift (24/7)	8,320 hours 24 hours/day, 7 days a week minus some holidays and scheduled down time
Unknown / Weighted average[1150]	5,702 hours

[1149] "Measured Loading of Energy Efficient Motors - the Missing Link in Engineering Estimates of Savings," ACEEE 1994 Summer Study Conference, Asilomar, CA.

[1150] Weighting of 16% single shift, 23% two shift, 25% three shift and 36% continual based on DOE evaluation of the Compressed Air Challenge, section 2.1.5 Facility Operating Schedules.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta \text{kW} = -\left(\text{HP}_{\text{motor}} \times 0.746 \times \frac{\text{LF}}{\eta_{\text{motor}}}\right) \times \text{CF}$$

Where:

CF = Summer Coincident Peak Factor for measure

Shift	Coincidence Factor
Single shift (8/5)	0.59
2-shift (16/5)	0.95
3-shift (24/5)	0.95
4-shift (24/7)	0.95
Unknown / Weighted average[1151]	0.89

FOSSIL FUEL SAVINGS (WATER SAVINGS MUST BE CALCULATED FIRST)

Fossil-fuel savings are calculated by estimating the amount of water that is discharged into the sewer. Savings are calculated on the enthalpy difference between make-up water and condensate temperature.

$$\Delta \text{Therms} = \frac{\Delta Water \times 8.33 \times (\text{H}_\text{r} - \text{H}_\text{w}) \times (1 - S_{loss})}{\eta_{\text{boiler}} \text{x } 100{,}000}$$

The calculated water savings (in gallons/year) is in turn, used to calculate fossil-fuel savings. The condition of condensate recovery systems varies widely between facilities. Flow meter readings or make-up water records are required for accurate calculations. For condensate systems where partial condensate is returned, a custom calculation is suggested.

$$\Delta \text{Water} = \left[\frac{\text{EFLH} \times \text{Capacity}}{[(\text{H}_\text{s} - \text{H}_\text{r})(\%_{\text{Existing}}) + (\text{H}_\text{s} - \text{H}_\text{w})(1 - \%_{\text{Existing}})] \times 8.33}\right]\left[\frac{\%_{\text{Proposed}} - \%_{\text{Existing}}}{1 - \%_{\text{Existing}}}\right]$$

ΔWater = Condensate water (gal) discharged into sewer that is saved after recovery systems are in place.

8.33 = specific mass in pounds of one gallon of water (lbm/gal)

= Actual if known.

EFLH = Equivalent Full Load hours for heating in Existing Buildings are provided in section 4.4 HVAC End Use

Capacity = Nominal Heating Input Capacity Boiler Size (Btu/hr) for existing unit

= Custom Boiler input capacity in btu/hr

H_s = Enthalpy of supplied steam[1152] (Btu/lbm)

[1151] Ibid.

[1152] Taken from IL TRM Measure 4.4.14 Pipe Insulation

System Type	Supply Fluid temperature [1153,1154] (˚F)	Enthalpy of steam or hot water (Btu/lbm)
5 psi Steam (low pressure)	225	1,155
15 psi Steam (low pressure)	250	1,163
40 psi Steam (low pressure)	287	1,176
65 psi Steam (high pressure)	312	1,183
100 psi Steam (high pressure)	338	1,190

H_r = Enthalpy of return steam (Btu/lbm)

The condensate fluid temperature assumption used depends upon both the system type and whether there are outdoor reset controls[1155]:

System Type	Return Fluid Temperature[1156] (˚F)	Enthalpy of condensate (Btu/lbm)
5 psi Steam (low pressure)	225	193
15 psi Steam (low pressure)	250	219
40 psi Steam (low pressure)	287	256
65 psi Steam (high pressure)	312	282
100 psi Steam (high pressure)	338	309
150 psi Steam (high pressure)	365	338

H_w = Enthalpy of incoming water from well or municipal system (Btu/lbm)

= 18.8 Btu/lbm for an incoming water temperature of 50.7°F [1157]

S_{loss} = Percentage of flash steam loss

= 12%[1158] or actual if known.

%existing = Percentage of existing condensate recovery

= 0% if no condensate is recovered or Actual If known

%proposed = Percentage of proposed condensate recovery

= 80%[1159] or actual if known

n_{boiler} = Efficiency of the steam boiler

= Actual or if unknown use default values given below:

[1153] A typical design uses a Δ20°F from hot water supply temperature to return temperature. ASHRAE. Boiler System Efficiency. 2006. http://goesheatingsystems.com/wp-content/uploads/2015/04/BoilerEfficiencyArticle.pdf

[1154] Typical hot water boiler operating temperature is 180°F. ASHARE. Boiler system Efficiency. 2006. http://goesheatingsystems.com/wp-content/uploads/2015/04/BoilerEfficiencyArticle.pdf

[1155] Taken from IL TRM Measure 4.4.14 Pipe Insulation

[1156] A typical design uses a Δ20°F from hot water supply temperature to return temperature. ASHRAE. Boiler System Efficiency. 2006. http://goesheatingsystems.com/wp-content/uploads/2015/04/BoilerEfficiencyArticle.pdf

[1157] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[1158] U.S. Department of Energy. Return Condensate to the Boiler. https://www.energy.gov/sites/prod/files/2014/05/f16/steam8_boiler.pdf

[1159] Okbaendrias, Biniam. Energy Management in Industries: Analysis of energy savings potential by steam condensate return. Page 10. About 75-85% of the total condensate return in reasonable.

= 79% for steam boilers[1160]

100,000 = Btu to therms for natural gas conversion factor. For other fossil-fuel, find appropriate conversion.

For example, for a Chicago 1,500 kbtu/hr steam boiler in an elementary school operating at 5 psi with a failed condensate return system.

ΔWater = (1,603 * 1,500,000)/((((1155-193)*0) + ((1155-18.8)*(1-0))) * 8.33)*((0.8-0)/(1-0))

= 203,243 gallons

ΔTherms = (203,243 * 8.33 * (193 - 18.8) * (1 – 0.12)) /(0.807 * 100,000)

= 3,216 therms

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

The methodology for calculating water savings involves obtaining the gallons of water that is dumped into the drain. Refer to fossil-fuel savings for calculation.

DEEMED O&M COST ADJUSTMENT CALCULATION

Maintenance personnel should complete annual or semi-annual maintenance inspections of the condensate return system for its optimal performance. The O&M cost shall be included in cost-effectiveness calculations. It is recommended to service the following components to maintain the system's proper operation: pumps, ensure periodic lubrication for motors, in accordance with the motor manufacturer's guidelines. Strainers, traps should also be included as an O&M consideration. A custom calculation should be used as necessary.

4.4.58 Steam Trap Monitoring System

DESCRIPTION

The measure applies to the installation of a steam trap monitoring system. The measure is applicable to commercial applications, commercial HVAC including multifamily buildings, and industrial applications. An existing measure, 4.4.16 Steam Trap Replacement or Repair, covers the replacement of a faulty steam trap in the failed open or leaking state. In addition to the steam trap replacement savings, the proposed measure allows to account for savings due to faster repair of the steam traps. Once a failed steam trap is detected, it can be immediately repaired/replaced. Continuous steam trap monitoring leaves behind manual inspections (audits) by using sensors to transmit real-time conditions of the steam system.

Energy savings for each steam trap occurs only when failed open, and steam trap failure rates vary based on trap size, type, and pressure. Energy savings are calculated on a per trap basis with the assumed annual failure rate for each application. Separate savings methodologies are recommended for space heating and process heating applications.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Customers must install a steam trap monitoring system on properly functioning steam traps serving either space heating or process heating load. The monitoring system must be capable of tracking the following, but not limited to, number of steam traps, trap type, operating pressure, operating temperature, ambient temperature, trap condition, date/time, application, and trap location. Applicants must provide characteristics for the steam system such as heating efficiency, steam trap orifice size(s), and system pressure(s). Customer must commit to repairing/replacing steam traps identified as failed by the steam trap monitoring system.

DEFINITION OF BASELINE EQUIPMENT

The baseline criterion are functioning steam traps serving either space heating or process heating load with no pre-existing monitoring system. No minimum leak rate is required.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

10 years based on vendor estimates.[1161]

DEEMED MEASURE COST

The costs are subject to the subscription period chosen by the customer as shown in table below. The approximate installed cost is per trap per year and includes sensors, gateway, cellular service, cloud hosting, User license, data, and reports.

Number of Traps	Term[1162]				
	1 Year	2 Years	3 Years	4 Years	5 Years
100 – 250	$300	$282	$265	$249	$234
250 – 499	$291	$274	$257	$242	$227
500 – 999	$282	$265	$249	$234	$220
1000 – 1999	$274	$257	$242	$227	$214
2000 – 2999	$266	$250	$235	$221	$207
3000 – 4999	$262	$246	$232	$218	$204
5000 – 5999	$258	$242	$228	$214	$201
6000 – 6999	$254	$238	$224	$210	$198

[1161] Measure life as referenced in Michigan CI Technologies & Franklin Energy "Work paper FES-H8a – Steam Trap Monitoring System" dated September 2016.

[1162] The Everactive Steam Trap Monitoring Service Price

Number of Traps	Term[1162]				
	1 Year	2 Years	3 Years	4 Years	5 Years
7000+	$251	$235	$221	$207	$196

Additional costs exist for the repair or replacement of steam traps once identifying a fault.

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure but should not be included in TRC tests to avoid double counting the economic benefit of water savings. These savings only apply to situations in which steam is lost from the steam system.

$$\Delta kWh_{water} = \Delta Water\ (gallons)/1{,}000{,}000\ \times E_{water\ supply}$$

Where:

$E_{water\ supply}$ = Water Supply Energy Factor (kWh/Million Gallons)

= 2571[1163]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

$$\Delta Therm = N\ \times P_{malfunctioning} \times F_o \times S_a \times \left(\frac{\left(Hv + Hs \times (T_1 - T_{source})\right) \times Hours}{(100{,}000 \times \eta_B)}\right)$$

Where:

N = Total number of steam traps monitored through the steam trap monitoring system

$P_{malfunctioning}$ = Annual Percentage of malfunctioning traps

$P_{malfunctioning} = L \times T_{audit} \times T_u$

Where:

L = Leaking & Blow-thru

= custom, if unknown:

[1163] This factor includes 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'. Note since the water loss associated with this measure is due to evaporation and does not discharge into the wastewater system, only the water supply factor is used here.

Steam System	L (%)[1164]
Commercial Dry Cleaners	27%
Commercial Heating (including Multifamily) LPS	27%
Industrial and Process Low Pressure ≤ 15 psig	16%
Medium Pressure > 15 psig < 30 psig	16%
Medium Pressure ≥ 30 < 75 psig	16%
High Pressure ≥ 75 < 125 psig	16%
High Pressure ≥ 125 < 175 psig	16%
High Pressure ≥ 175 < 250 psig	16%
High Pressure ≥ 250 < 300 psig	16%
High Pressure ≥ 300 psig	16%

T_{audit} = Average time between audits

Custom, if unknown use 1 year

Tu = Average percentage of year trap malfunctions are undetected for steam systems without a steam trap monitoring system

Custom, if unknown use 50%[1165]

F_o = Failed open to total failed ratio

= Custom, if unknown: [1166]

96%, Space heating applications

98%, Dry cleaners

94%, All other steam systems and applications

S_a = Steam loss per leaking trap, (lbs/hr)

Hv = Heat of vaporization of steam, (Btu/lbm)

Steam System	Average Inlet Pressure psig	Heat of Vaporization (Btu/lbm)[1167]
Commercial Dry Cleaners	82.8[1168]	890

Steam System	Zone (Where applicable)	Hours/Yr[1171]
	opens/closes to maintain setpoint temperature, use Heating EFLH values in Section 4.4 for High Rise or Mid-Rise MF buildings. For steam traps that are exposed to steam continuously throughout the heating season, use the values listed above for Commercial Space Heating LPS for your appropriate climate zone.	

100,000 = Conversion factor $(Btu/Therms)$

η_B = Boiler efficiency

= custom, if unknown:

79% for steam boilers[1172]

Low-Pressure System (≤ 5psig) Space Heating Savings Estimates

For systems used in space heating applications that operate at 5 psig or lower, use the following equation to calculate S_a[1173]. The condensate return system pressure, P_2, will typically be atmospheric pressure, 14.696 psia.

$$S_a = 1{,}519.3 \times P_1 \times D^2 \times \left[\left({}^{1}/_{T_1}\right) \times \left({}^{\gamma}/_{(\gamma-1)}\right) \times \left(\left({}^{P_2}/_{P_1}\right)^{({}^{2}/_{\gamma})} - \left({}^{P_2}/_{P_1}\right)^{({}^{(\gamma+1)}/_{\gamma})}\right)\right]^{0.5} \times A \times FF$$

Where:

1,519.3 = Constant, $(s^2 \times {}^{\circ}R^{0.5})/(ft \times hr)$

P_1 = Average steam trap inlet pressure $(absolute, psia)$. If not available, apply a assumed default pressure of 5 psig (note that the default is provided in psig, not psia; to calculate the default psia add atmospheric pressure, 14.696, to the assumed gauge pressure, psig)

D = Diameter of orifice, inches. Actual value should be used wherever possible as this value has a significant impact on steam flowrate value.

γ = Heat Capacity Ratio $(unitless)$

= $5.071 \times 10^{-4} \times P_1 + 1.332$

P_2 = Average steam trap outlet pressure $(absolute, psia)$. If unknown, assume atmospheric pressure, $14.696\ psia$

A = Adjustment factor

= 50%,[1174] all steam systems. This factor accounts for reduction in the maximum theoretical steam flow to the average steam flow (the Enbridge factor).

FF = Flow factor. In addition to the Adjustment factor (A), and additional 50% flow factor adjustment is recommended for medium and high-pressure steam systems to address industrial float and thermostatic style traps where additional blockage is possible.

[1172] Federal Register, volume 74, Number 139, July 22, 2009 for boilers >300,000 Btu/hr

[1173] See "Derivation of Equation for Subsonic Compressible Flow through an Orifice and Supporting Calculations for Illinois TRM Steam Trap Measure" paper for more information

[1174] Enbridge adjustment factor used as referenced in CLEAResult "Work paper Steam Traps Revision #2" Revision 3 dated March 2, 2012 and DOE Federal Energy Management Program Steam Trap Replacement Assessment.

Defaults are provided in table below if custom calculation is not performed. The savings are averages for common orifice diameters $\left({}^{1}/_{8}, {}^{3}/_{16}, {}^{1}/_{4}, {}^{5}/_{16}\, inches\right)$ at an assumed 5 psig.

Savings per Steam Trap Orifice Size[1175]		1/8	3/16	1/4	5/16
S_a	(lbs/hr)	3.84	8.64	15.35	23.99
ΔTherms	(Therms/trap/yr)	14.23	32.02	56.92	88.94

Process Heating and Low, Medium and High-Pressure Systems (>5 psig) Savings Estimates

Use the following equation, for all other steam systems and applications

$$S_a = 24.24 \times P_1 \times D^2 \times A \times FF$$

Where:

24.24 = Constant, $lbm/(hr \times psia \times in^2)$

P_1 = Average steam trap inlet pressure $(absolute, psia)$. If not available, use defaults provided in table below (note that default are provided in psig, not psia; to calculate the default psia add atmospheric pressure, 14.696, to the assumed gauge pressure, psig) Defaults are provided in table below if custom calculation is not performed. Multifamily Space Heating LPS and High Pressure systems over 300 psig require custom calculations.

Steam System	Climate Zone (if applicable)	Average Steam Trap Inlet Pressure (psig) [1177]	Diameter of Orifice (in)	Adjustment Factor	Flow Factor	Sa[1176] (lbs/trap/hr)	ΔTherm

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

The hourly water volume saved per each repaired or replaced leaking trap is calculated by dividing the "Steam Loss per Leaking Trap (lbm/hr/trap)" by the density of water saved, 8.33 lbm/gal, that replaces the lost steam. The steam loss is provided in the table for parameter S_a, the "Steam loss per leaking trap" in the Fossil Fuel savings section above. Annual water savings are calculated using Hours and $P_{malfunctioning}$, the annual percentage of malfunctioning traps, as defined above.

Water savings only apply to situations where condensate is lost from the steam system. If a condensate recovery system is in place, assume zero water savings or provide a custom calculation based on site-specific operation.

The annual water savings for a replaced or repaired trap is given by:

$$\Delta Water = GAL \times Hours \times N \times P_{malfunctioning} \times F_o$$

Where:

GAL = average actual water volume saved per leaking trap, as listed in the following table and based on steam system type.

Other variables as defined above

Steam System	S_a	GAL (gal/hr/trap)
Commercial Dry Cleaners	18.5	2.22
Commercial LPS Space Heating (Including Multifamily)	13.8	0.83
Industrial/Process Low Pressure: psig < 15	13.8	1.66
Medium Pressure: 15 ≤ psig < 30	6.5	0.79
Medium Pressure: 30 ≤ psig < 75	23.4	2.81
High Pressure: 75 ≤ psig < 125	43.8	5.26
High Pressure: 125 ≤ psig < 175	60.9	7.31
High Pressure: 175 ≤ psig < 250	82.1	9.85

[1179] Ibid.

Steam System	S_a	GAL (gal/hr/trap)
High Pressure: 250 ≤ psig < 300	105.2	12.63
High Pressure: 300 ≤ psig	Calculated	Calculated Steam Loss / 8.33

MEASURE CODE: CI-HVC-STMS-V3-260101

REVIEW DEADLINE: 1/1/2028

4.4.59 Ductless Heat Pumps - Removed in v.13

Measure now combined with 4.4.9 Air and Water Source Heat Pump System (Centrally Ducted and Ductless)

4.4.60 Variable Refrigerant Flow HVAC System

DESCRIPTION

This measure applies to the installation of air source Variable Refrigerant Flow (VRF) HVAC systems. VRF systems are heat pumps that have one outdoor condensing unit with refrigerant piped to multiple indoor evaporator units to deliver cooling and/or heating to individual interior zones as needed. This measure could apply to replacing an existing unit at the end of its useful life or the installation of a new unit in a new or existing building.

This measure was developed to be applicable to the following program times: TOS and NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure applies to both retrofit and new construction installations of VRF systems. Savings are based in the inherent efficiency of VRF systems as compared to traditional HVAC systems. VRF systems should meet or exceed ASHRAE 90.1 minimum efficiency requirements for air source VRF systems.

DEFINITION OF BASELINE EQUIPMENT

Time of Sale / New Construction

Non-fuel switch measures:

To calculate savings with an electric baseline, the baseline equipment is assumed to be a ducted split-system heat pump for non-residential buildings 25,000 square feet or fewer and is 3 floors or fewer. For non-residential buildings over 25,000 square feet or 4 floors or higher, the baseline equipment is assumed to be a standard-efficiency air cooled heat pump roof top unit (RTU) system. For residential buildings types which utilize individual in-unit HVAC systems, such as multifamily, lodging, dormitories, etc., the baseline equipment is assumed to be a residential style standard-efficiency packaged terminal heat pump split system.

Fuel switch measures:

To calculate savings with a gas or fuel heating baseline, the baseline equipment is assumed to be single zone furnace and air-conditioning units for non-residential buildings 25,000 square feet or fewer and is 3 floors or fewer. For non-residential buildings over 25,000 square feet or taller than 3 floors, the baseline equipment is assumed to be a packaged variable-air-volume (VAV) system with DX cooling and hot water reheat. For residential buildings types which utilize individual in-unit HVAC systems, such as multifamily, lodging, dormitories, etc., the baseline equipment is assumed to be a packaged terminal air conditioner (PTAC) with hot-water radiator heating. If the residential building is 4 stories or more, the baseline system will be a water source heat pump (WSHP) system with a boiler and cooling tower.

In order for this characterization to apply, the baseline equipment is assumed to meet the efficiency requirements within the IECC code in effect on the date of the building permit. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

Standard efficiency implies equipment that complies with Code energy efficiency requirements (IECC or Code of Federal Regulations, whichever is higher) in effect on the date of equipment purchase (if date unknown, assume current Code minimum). The rating conditions for the baseline and efficient equipment efficiencies must be equivalent

Note, IECC 2021 became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code. If evaluation determines the applicable version of code, given location and timing, isn't an appropriate baseline due to supply constraints, low compliance, or other issues, the previous iteration of code may be used through 2023.

IECC 2021 leverages new DOE testing methods and associated metrics. The following conversion factors are recommended for use if the efficient equipment is not rated under the new testing procedure but the stipulated baseline is:[1180]

SEER2 = X * SEER

EER2 = X * EER

HSPF2 = X * HSPF

Where:

X	SEER2	EER2	HSPF2
Ducted	0.95	0.95	0.85
Ductless	1.00	1.00	0.90
Packaged	0.95	0.95	0.84

Baseline selection:

The following table can be used to determine the appropriate baseline HVAC system type.

	Non-Fuel Switch	Fuel Switch
Multifamily or Lodging, 3 floors or fewer	Packaged Terminal Heat Pump	PTAC w/ Hot Water Radiator
Multifamily or Lodging, 4 floors or more	Packaged Terminal Heat Pump	Water Source Heat Pump with Cooling Tower and Natural Gas Boiler
Non-residential <25,000 SF and 3 floors or fewer	Ducted-Split System Heat Pump	Packaged Single Zone (Furnace) + Air Conditioner
Non-Residential >25,000 SF OR more than 3 floors	Heat Pump RTU	Packaged VAV RTU with Hot Water Reheat

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for VRF is 16 years[1181].

DEEMED MEASURE COST

Time of Sale: For analysis, the incremental capital costs are summarized in the following table. Site specific cost data should be used where available.

Baseline System	Incremental Cost ($/ton) [1182]
Packaged Terminal Heat Pump	$610
Ducted Split System Heat Pump	$860

[1180] Consortium for Energy Efficiency (CEE), Testing, Testing, M1, 2, 3, Transitioning to New Federal Minimum Standards, CEE Summer Program Meeting, August, 2022.

[1181] Consistent with Residential air source heat pump measure and based on a 2016 DOE Rulemaking Technical Support document, as recommended in Guidehouse 'ComEd Effective Useful Life Research Report', May 2018.

[1182] Estimated measure incremental costs for PTHP, HP RTU and PTAC based other incremental costs and differences in installed cost from U.S. Energy Information Administration (EIA), Updated Buildings Sector Appliance and Equipment Costs and Efficiencies: https://www.eia.gov/analysis/studies/buildings/equipcosts/pdf/full.pdf. For Ducted Split HP, Packaged Single Zone Furnace + AC and Packaged VAV RTU is based on Mid-Atlantic Technical Reference Manual version 9, Variable Refrigerant Flow (VRF) Heat Pump Systems measure. Published October, 2019. Water-source HP systems estimated from data collected from manufacturers. Water-source heat pump systems were not very different compared to VRF systems.

Baseline System	Incremental Cost ($/ton) [1182]
Heat Pump RTU	$130
PTAC w/ Hot Water Radiator	$160
Water Source Heat Pump	$0
Packaged Single Zone (Furnace) + Air Conditioner	$835
Packaged VAV RTU with Hot Water Reheat	$540

LOADSHAPE

Loadshape C05 – Commercial Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits. The second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)
= 91.3%[1183]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)
= 47.8%[1184]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Savings are calculated as a sum of system switching savings and efficiency savings, analogous to the following equation:

$$\text{Annual Savings} = [System\ Switch\ Savings] + [Savings\ from\ improved\ VRF\ efficiency]$$

For fuel-switching calculations, the above equation is used for calculating the cooling savings, while the heating savings are calculated by as the following:

$$\text{Annual Savings} = [Gas\ Heat\ Replaced\ x\ System\ Switch\ Adjustment\ Factor] + [Fan\ Savings] - [Heat\ Pump\ heat\ consumed\ x\ System\ Switch\ Adjustment\ Factor] + [Heat\ Pump\ Cooling\ *\ System\ Switch\ Savings + Heat\ Pump\ Cooling\ Savings\ from\ improved\ VRF\ efficiency]$$

The system switching savings are calculated by multiplying the cooling or heating load (EFLH times heat or cool capacity) and multiplying it by system heating ($Heat_{adj}$) and cooling ($Cool_{adj}$) factors. These adjustment factors were calculated with energy model data of different building types. The VRF performance curves were calibrated based on independent field monitored data.

- The difference in building code baseline efficiency between VRF and the baseline system.

[1183] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[1184] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

- The improved part load performance of the VRF inverter driven compressor compared to single-stage or two-stage compressors.
- Heat recovery mode savings from the VRF units.
- Decrease in energy from cooling towers (WSHP baseline) and water pumps (baseline systems with hot water and WSHP).
- WSHP electric heating and boiler fuel consumption (WSHP baseline).
- Differences in treating ventilation between mixed recirculating systems and VRF systems with dedicated outdoor air systems (Heat Pump RTU and VAV baseline systems only).

Savings from improved VRF efficiency is similar to other efficiency savings from other TRM measures, where savings are calculated as the load multiplied by the change in efficiency.

Non-fuel switch measures:

For units with cooling capacities less than 65 kBtu/hr:

ΔkWh = $Annual\ kWh\ Savings_{cool} + Annual\ kWh\ Savings_{heat} + FanSavings$

Annual kWh Savings$_{cool}$ = $[System\ Switch\ Savings] + [Savings\ from\ improved\ VRF\ efficiency]$

= $(Cool_{adj} * Capacity_{cool} * EFLH_{cool}/3{,}412) + (Capacity_{cool} * EFLH_{cool} * (1/SEER2base - 1/SEER2ee))/1000$

Annual kWh Savings$_{heat}$ = $[System\ Switch\ Savings] + [Savings\ from\ improved\ VRF\ efficiency]$

FanSavings = $(Heat_{adj} * HeatLoad/3{,}412) + (HeatLoad * (1/HSPF2base - 1/HSPF2ee))/1000$

= $(Flag * HeatLoad * 1/AFUE_{base} * F_e) / 3{,}412$

For units with cooling capacities equal to or greater than 65 kBtu/hr:

ΔkWh = $Annual\ kWh\ Savings_{cool} + Annual\ kWh\ Savings_{heat} + FanSavings$

Annual kWh Savings$_{cool}$ = $[System\ Switch\ Savings] + [Savings\ from\ improved\ VRF\ efficiency]$

= $(Cool_{adj} * Capacity_{cool} * EFLH_{cool}/3{,}412) + (Capacity_{cool} * EFLH_{cool} * (1/EERbase - 1/EERee))/1000$

Annual kWh Savings$_{heat}$ = $[System\ Switch\ Savings] + [Savings\ from\ improved\ VRF\ efficiency]$

FanSavings = $(Heat_{adj} * HeatLoad)/3{,}412 + (HeatLoad * (1/COPbase - 1/COPee))/3{,}412$

= $(Flag * HeatLoad * 1/AFUE_{base} * F_e) / 3{,}412$

Fuel switch measures:

Fuel switch measures must produce positive total lifecycle site energy savings in order to qualify. This is determined as follows (note for early replacement measures the lifetime savings should be calculated by calculating savings for the remaining useful life of the existing equipment and for the remaining measure life):

SiteEnergySavings (MMBTU) = $GasHeatReplaced + FanSavings - HPSiteHeatConsumed + HPSiteCoolingImpact$

GasHeatReplaced (MMBTU) = $(GasHeat_{adj} * HeatLoad * 1/AFUE_{base}) / 1{,}000{,}000$

FanSavings (MMBTU) = $(Flag * HeatLoad * 1/AFUE_{base} * Fe)$ / 1,000,000

For units with cooling capacities less than 65 kBtu/hr:

HPSiteHeatConsumed (MMBTU) = $(Heat_{adj} * HeatLoad * (1/HSPFee)) * 3{,}412$ / 1,000 / 1,000,000

HPSiteCoolingImpact (MMBTU) =$[System\ Switch\ Savings]$ + $[Savings\ from\ improved\ VRF\ efficiency]$

= $((Cool_{adj} * Capacity_{cool} * EFLHcool)$ / 1,000,000) + $((EFLHcool * Capacity_{cool} * (1/SEER2base - 1/SEER2ee)) * 3{,}412$ / 1,000 / 1,000,000)

For units with cooling capacities greater than 65 kBtu/hr:

HPSiteHeatConsumed (MMBTU) = $(Heat_{adj} * HeatLoad * (1/COPee))$ / 1,000,000

HPSiteCoolingImpact (MMBTU) =$[System\ Switch\ Savings]$ + $[Savings\ from\ improved\ VRF\ efficiency]$

= $((Cool_{adj} * Capacity_{cool} * EFLHcool)$ / 1,000,000) + $((EFLHcool * Capacity_{cool} * (1/EER_base - 1/EER_ee)) * 3{,}412$ /1,000 / 1,000,000)

Savings are adjusted by heating ($Heat_{adj}$) and cooling ($Cool_{adj}$) factors presented in the following table. These values bring the expected savings in line with energy model estimated savings.

Baseline System	$GasHeat_{adj}$	$Cool_{adj}$	$Heat_{adj}$
Packaged Terminal Heat Pump	N/A	0.1	0.0
Ducted Split System Heat Pump	N/A	0.0	0.0
Heat Pump RTU	N/A	-0.2	0.5
PTAC w/ Hot Water Radiator	0.7	0.0	1.3
Water Source Heat Pump	0.4	0.1	0.5
Packaged Single Zone (Furnace) + Air Conditioner	1.4	0	1.6
Packaged VAV RTU with Hot Water Reheat	0.9	-0.2	1.8

If SiteEnergySavings calculated above is positive, the measure is eligible. The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note: utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:

$Cool_{adj}$ = This cooling adjustment factor is derived from energy modeling results to calibrate TRM calculation savings to energy modeling savings estimates.[1185] Adjustment factor values are presented in a table above.

$Heat_{adj}$ = This heating adjustment factor is derived from energy modeling results to calibrate TRM calculation savings to energy modeling savings estimates.[1186] Adjustment factor values are presented in a table above.

$GasHeat_{adj}$ = This gas heating adjustment factor is derived from energy modeling results to calibrate TRM calculation savings to energy modeling savings estimates.[1187] Adjustment factor values are presented in a table above.

$Capacity_{cool}$ = input capacity of the cooling equipment in Btu per hour (1 ton of cooling capacity equals 12,000 Btu/hr).

= Actual installed

SEER2base =Seasonal Energy Efficiency Ratio of the baseline equipment

= SEER from tables below, based on the applicable Code on the date of equipment purchase (if unknown assume current Code).

SEER2ee = Seasonal Energy Efficiency Ratio of the energy efficient equipment.
= Actual installed

$EFLH_{cool}$ = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

HSPF2base = Heating Seasonal Performance Factor of the baseline equipment

= HSPF from tables below, based on the applicable Code on the date of equipment purchase (if unknown assume current Code).

HSPF2ee = Heating Seasonal Performance Factor of the energy efficient equipment.
= Actual installed. If rating is COP, HSPF = COP * 3.413

EERbase = Energy Efficiency Ratio of the baseline equipment

= EER from tables below, based on the applicable Code on the date of equipment purchase (if unknown assume current Code). For air-cooled units < 65 kBtu/hr, assume the following conversion from SEER to EER for calculation of peak savings[1188]:

$EER = (-0.02 * SEER_2) + (1.12 * SEER)$

EERee = Energy Efficiency Ratio of the energy efficient equipment. For air-cooled units < 65 kBtu/hr, if the actual EERee is unknown, assume the conversion from SEER to EER as provided above.

= Actual installed

EER2base = Energy Efficiency Ratio of the baseline equipment

[1185] Based on Variable Refrigerant Flow Study. See 'Variable Refrigerant Flow Study 2023'.
[1186] Based on Variable Refrigerant Flow Study. See 'Variable Refrigerant Flow Study 2023'.
[1187] Based on Variable Refrigerant Flow Study. See 'Variable Refrigerant Flow Study 2023'.
[1188] Based on Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder. Note this is appropriate for single speed units only.

= EER2 from tables below, based on the applicable Code on the date of equipment purchase (if unknown assume current Code). For air-cooled units < 65 kBtu/hr, assume the following conversion from SEER2 to EER2 for calculation of peak savings[1189]:

$EER2 = (-0.02 * SEER2^2) + (1.12 * SEER2)$

EERee = Energy Efficiency Ratio of the energy efficient equipment. For air-cooled units < 65 kBtu/hr, if the actual EERee is unknown, assume the conversion from SEER to EER as provided above.

= Actual installed

HeatLoad = Calculated heat load for the building

$= EFLH_{heat} * Capacity_{heat}$

Where:

$EFLH_{heat}$ = heating mode equivalent full load hours in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

$Capacity_{heat}$ = Actual installed input capacity of the heat pump equipment in Btu per hour.

3412 = Btu per kWh.

COPbase = coefficient of performance of the baseline equipment

= COP from tables below, based on the applicable Code on the date of equipment purchase (if unknown assume current Code).

If rating is HSPF, COP = HSPF / 3.413

COPee = coefficient of performance of the energy efficient equipment.

= Actual installed. If rating is HSPF, COP = HSPF / 3.413

AFUEbase = Baseline Annual Fuel Utilization Efficiency Rating. Use appropriate code level efficiency.

Flag = 1 if system replaced is an RTU or ducted system with furnace fan, 0 if not.

F_e = Fan energy consumption as a percentage of annual fuel consumption

= 7.7% for RTU replacement, 3% for multifamily (residential style) furnace replacement[1190]

%IncentiveElectric = % of total incentive paid by electric utility

= Actual

%IncentiveGas = % of total incentive paid by gas utility

= Actual

[1189] Based on Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder. Note this is appropriate for single speed units only.

[1190] Fe is estimated using TRM models for the three building types: low-rise office, sit-down restaurant and retail-strip mall. 7.7% represents the average Fe of the three building types. See "Fan Energy Factory Example Calculation 2021-06-23.xlsx" for reference. Mutlifamily is 3%, lower than commercial, due to typically lower fan static pressure in residential style applications.

Equipment Type	Size Category	Heating Section Type	Subcategory or Rating Condition	Minimum *Efficiency*	Test Procedure
VRF air cooled (cooling mode)	<65,000 Btu/h	All	*VRF* multisplit *system*	13.0 *SEER*	AHRI 1230
	≥65,000 Btu/h and <135,000 Btu/h	*Electric resistance* (or none)		11.0 *EER* 12.9 *IEER*14.6 *IEER*	
			VRF multisplit *system* with heat recovery	10.8 *EER* 12.7 *IEER* 14.4 *IEER*	
	≥135,000 Btu/h and <240,000 Btu/h		*VRF* multisplit *system*	10.6 *EER* 12.3 *IEER* 13.9 *IEER*	
			VRF multisplit *system* with heat recovery	10.4 *EER* 12.1 *IEER* 13.7 *IEER*	
	≥240,000 Btu/h		*VRF* multisplit *system*	9.5 *EER* 11.0 *IEER* 12.7 *IEER*	
			VRF multisplit *system* with heat recovery	9.3 *EER* 10.8 *IEER* 12.5 *IEER*	
VRF air cooled (heating mode)	<65,000 Btu/h (cooling capacity)		*VRF* multisplit *system*	7.7 *HSPF*	AHRI 1230
	≥65,000 Btu/h and <135,000 Btu/h (cooling capacity)		*VRF* multisplit *system* 47°F db/43°F wb *outdoor air*	3.3 COP_H	
			17°F db/15°F wb *outdoor air*	2.25 COP_H	
	≥135,000 Btu/h (cooling capacity)		*VRF* multisplit *system* 47°F db/43°F wb *outdoor air*	3.2 COP_H	
			17°F db/15°F wb *outdoor air*	2.05 COP_H	

Non Fuel Switch example, a heat recovery VRF system with 8 ton cooling capacity and 96 kbtu heating capacity, an efficient EER of 12.5 and COP of 3.75, at a new construction low-rise office in Chicago saves:

ΔkWh = $Annual\ kWh\ Savings_{cool} + Annual\ kWh\ Savings_{heat} + FanSavings$

Annual kWh Savingscool = $(Cooladj * Capacitycool * EFLHcool\ /\ 3412) + (Capacitycool * EFLHcool * (1/EERbase - 1/EERee))/1000$

Annual kWh Savingsheat = $(Heatadj * Heat\ Load\ /\ 3412) + (HeatLoad * (1/COPbase - 1/(COPee))/3412$

FanSavings = $(Flag * HeatLoad * 1/AFUEbase * Fe)\ /\ 3412$

ΔkWh = $(0.0 * 96000 * 989/3{,}412) + (96000 * 989 * (1/10.8 - 1/12.5)/1000 + (0.0 * 916 * 60000/3412) + (916 * 60000 * (1/3.3 - 1/3.75)\ /\ 3412) + (1 * 916 * 60000 * 1/0.8 * 0.077)\ /\ 3412$

ΔkWh = $3332\ kWh$

Fuel Switch example, a heat recovery VRF system with 8-ton cooling capacity and 96 kbtu heating capacity, an efficient EER of 12.5 and COP of 3.75, at a new construction low-rise office in Chicago, assuming a packaged single zone (furnace) and air conditioner baseline. Assuming 50%-50% Incentive agreement is used for joint programs, savings:

SiteEnergySavings (MMBTUs) = $GasHeatReplaced + FanSavings - HPSiteHeatConsumed + HPSiteCoolingImpact$

GasHeatReplaced = $(GasHeat_{adj} * HeatLoad * 1/AFUE_{base})$ / 1,000,000

= $1.4 * (96000 * 916 * 1/0.8)$ / 1000000

= 153.9 $MMBtu$

FanSavings = $(Flag * HeatLoad * 1/AFUE_{base} * F_e)$ / 1,000,000

= $(1 * 96000 * 916 * 1/0.8 * 0.030)$ / 1000000

= 3.30 $MMBtu$

For units with cooling capacities greater than 65 kBtu/hr:

HPSiteHeatConsumed = $(Heat_{adj} * HeatLoad * (1/COPee))$ / 1,000,000

= $(1.6 * 96000 * 916 * (1/3.75))$ / 1,000,000

= 37.9 $MMBtu$

HPSiteCoolingImpact = $(Cool_{adj} * Capacity_{cool} * EFLH_{cool}$ / 1,000,000) $* (FLHcool * Capacity_{cool} * (1/EERbase - 1/EERee)) * 3{,}412$ / 1,000 / 1,000,000

= $((0.0 * 989 * 96000)/1{,}000{,}000) + (989 * 96000 * (1/10.8 - 1/12.5)) * 3{,}412$ / 1,000 / 1,000,000

= 4.1 $MMBtu$

SiteEnergySavings (MMBTUs) = $153.9 + 3.30 - 37.9 + 4.1 = 123.3$ [$Measure\ is\ eligible$]

Savings would be claimed as follows, assuming a 50%-50% incentive agreement:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	123.3 * 1,000,000/3,412 = 36,148 kWh	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	0.5 * 123.3 * 1,000,000/3,412 = 18,074 kWh	0.5 * 88.9 * 10 = 617 therms
Gas utility only	N/A	123.3 * 10 = 1,233 therms

SUMMER COINCIDENT PEAK DEMAND SAVINGS

For units with cooling capacities less than 65 kBtu/hr:

$$\Delta kW = \left(\frac{Capacity_{cool}}{1{,}000} * \left(\frac{1}{EER2base} - \frac{1}{EER2ee}\right)\right) * CF$$

For units with cooling capacities greater than 65 kBtu/hr:

$$\Delta kW = \left(\frac{Capacity_{cool}}{1{,}000} * \left(\frac{1}{EERbase} - \frac{1}{EERee}\right)\right) * CF$$

Where CF value is chosen between:

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8%

For example, a heat recovery VRF system with 8-ton cooling capacity and 96 kbtu heating capacity, an efficient EER of 12.5, saves:

ΔkW = (96,000/1,000 * (1/10.8 – 1/12.5)) *0.913

= 1.1 kW

FOSSIL FUEL SAVINGS

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from gas to electric.

For the purposes of forecasting load reductions due to fuel switch ASHP projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = $[Heating\ Consumption\ Replaced]$
= $[GasHeat_{Adj} * HeatLoad * 1/AFUE_{base}) / 100{,}000]$

ΔkWh = $[FurnaceFanSavings] - [HP\ heating\ consumption] + [Cooling\ savings]$

For units with cooling capacities less than 65 kBtu/hr:

$$\Delta kWh = [FurnaceFlag * HeatLoad * 1/AFUE_{base} * F_e * 0.000293] - [Heat_{Adj} * HeatLoad/3412 * (1/(COP_{ee}))/1000] + [Cool_{adj} * (Capacity_{cool} * EFLH_{cool} * (1/EER2base - 1/EER2_ee))/1000]$$

For units with cooling capacities greater than 65 kBtu/hr:

$$\Delta kWh = [FurnaceFlag * HeatLoad * 1/AFUE_{base} * F_e * 0.000293] - [Heat_{adj} * HeatLoad/3412 * (1/COP_{ee})] + [Cool_{adj} * (Capacity_{cool} * EFLH_{cool} * (1/EERbase - 1/EER_ee))/1000]$$

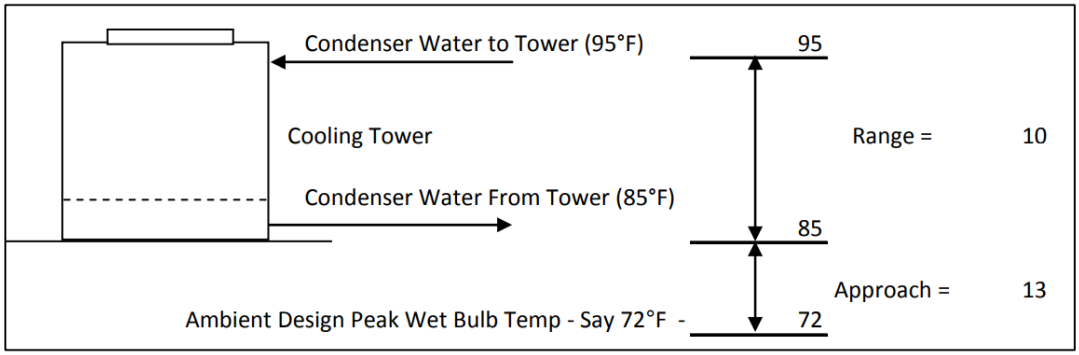
MEASURE CODE: CI-HVC-VFFY-V5-260101

REVIEW DEADLINE: 1/1/2030

4.4.61 Chiller Condenser Water Temperature Reset

DESCRIPTION

Condenser water temperature reset – reset the constant condensing loop supply temperature from constant 80°F to a dynamic range of 70°F to 80°F based on the outdoor-air wet-bulb temperature (WBT). When the outdoor-air wet-bulb temperature is below 60°F, reset the condensing loop set point to 70°F. When the outdoor-air wet-bulb temperature is above 70°F, reset to 80°F; when the outdoor-air wet-bulb temperature is in between, reset the condensing supply temperature to 10°F higher than the outdoor-air wet-bulb temperature. The chiller COP (coefficient of performance) increases after the measure is applied. However, the condenser loop balances out the energy saving because the cooling tower fan works harder and longer to cool condensing water to a lower temperature. The resulting savings (primarily cooling) from this measure are roughly proportional to the amount of part-load cooling that is required in the baseline and range between 0.1% and 1.3%.



DEFINITION OF EFFICIENT EQUIPMENT

This measure is applicable when the condenser water temperature (CWT) setpoint is either not resetting properly, or a reset strategy is not implemented. The minimum setpoint is set to 70°F.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is fixed condenser water temperature of 85°F. Only applicable to water-cooled chillers.

Baseline Data Collection:

- Trend Current outdoor air dry bulb and wet bulb temperatures
- Trend Current entering condenser water supply temperature
- Trend Current leaving chilled water temperature

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected lifetime of the measure is 10 years[1191]

DEEMED MEASURE COST

Use actual chiller manufacturer provided cost.

LOADSHAPE

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8%[1193]

Algorithm

CALCULATION OF ENERGY SAVINGS

Efficient Data Collection:

1 Trend outdoor air dry bulb and wet bulb temperatures
2 Trend entering condenser water supply temperature
3 Trend leaving chilled water temperature
4 Trend energy usage (kWh)
5 Model weather bin data
6 Trend condenser water supply temperature and temperature setpoint, and whatever parameter the reset is based on (e.g., outside air dry bulb and wet bulb temperatures).
7 Perform functional testing if independent variables at the time of trending do not cover the range covered by the reset.

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = TONS * ((IPLVbase) - (CPLVee)) * EFLH$$

Where:

TONS = Chiller nominal cooling capacity in tons (note: 1 ton = 12,000 Btu/hr)

= Actual installed

$IPLV_{base}$ = Efficiency of baseline equipment expressed as Integrated Part Load Value (kW/ton). Chiller units are dependent on chiller type. See Chiller Units, Conversion Values and Baseline Efficiency Values by Chiller Type and Capacity in the 4.4.6 Electric Chiller measure Reference Tables section.

$CPLV_{ee}$ = Calculated Part Load Value based on trend data post measure install (kW/ton)

= Actual installed

EFLH = Equivalent Full Load Hours for cooling in Existing Buildings or New Construction are provided in section 4.4 HVAC End Use.

[1192] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[1193] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kWSSP = TONS * ((PEbase) - (PEee)) * CFSSP$$

$$\Delta kWPJM = TONS * ((PEbase) - (PEee)) * CFPJM$$

Where:

PE_{base} = Peak efficiency of baseline equipment expressed as Full Load (kW/ton)

PE_{ee} = Peak efficiency of high efficiency equipment expressed as Full Load (kW/ton)

= Actual installed

4.4.62 Cooling Tower Water Side Economizer

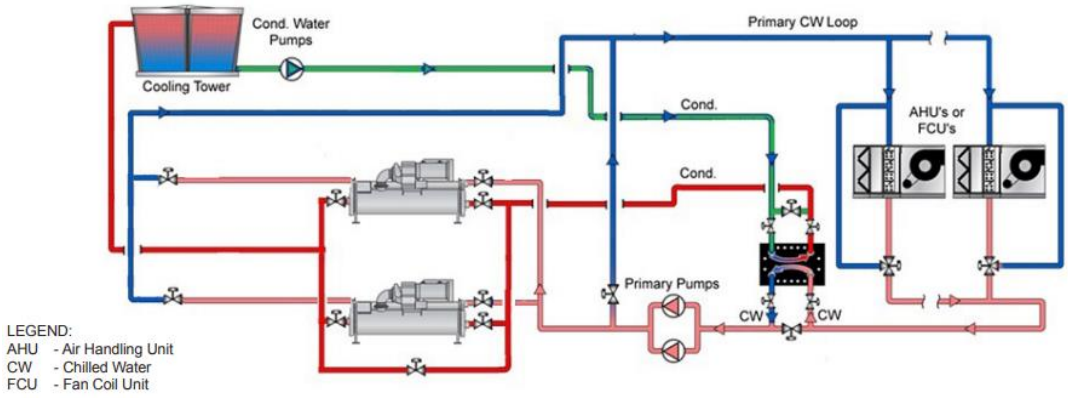
DESCRIPTION

A waterside economizer works by running the cooling tower loop in the winter and parts of the shoulder seasons as a source of cooling and transferring cooling energy to the building (secondary) cooling loop. This requires a dedicated plate-and-frame heat exchanger that is used only during waterside economizer operations, during which time the chillers are locked out.

A waterside economizer may contribute to reduced energy use in the following ways:

- Reducing the mechanical cooling load on chillers by pre-cooling return water
- Reducing energy use of the plant by allowing chillers to turn off at times of free cooling

Energy consumption (kWh) may decrease with the use of a waterside economizer because the leaving chilled water temperature can be reduced based on the wet bulb temperature. With this control strategy, the effect will be a reduction in motor speed (rpms) of the compressor as well as the pre-cooling of the chilled water return through the waterside economizer.



DEFINITION OF EFFICIENT EQUIPMENT

Installation of integrated waterside economizer heat exchanger to existing chilled-water system with cooling tower. Heat exchanger approach may range from 1º to 6º. Weather data is used to identify the annual hours in which outdoor air conditions are sufficient to provide water at a desirable temperature. Typically, demand savings may not be present with this measure because the process systems require water temperatures around 55-65°F and a cooling tower cannot meet these temperatures during the peak period.

DEFINITION OF BASELINE EQUIPMENT

No waterside heat exchanger installed or functional.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected lifetime of the measure is 10 years[1194]

DEEMED MEASURE COST

Use actual chiller manufacturer provided cost.

LOADSHAPE

Loadshape C03 - Commercial Cooling

4.4.63 Boiler Blowdown Heat Recovery

DESCRIPTION

This measure is for a non-residential steam boiler serving process load or space heating. The measure applies to steam natural gas fired boilers where the continuous blowdown exceeds 5% of the steam rate[1197]. Blowdown heat recovery systems should also be considered when about 500lbs/hr of steam is blown down and for continuous blowdown systems of at least 1 gpm[1198]. All steam boilers must blow down to reduce the amount of dissolved solids in the boiler water. However, along with the solids, boiler chemicals and thermal energy is lost. Although blowdown heat recovery systems cannot recover the chemicals, they do recover up to 90% of the heat energy that would otherwise be lost down the drain[1199]. Blowdown waste heat can be recovered with a heat exchanger, a flash tank, or a flash tank in a combination with a heat exchanger. The recovered heat is used to pre-heat boiler make-up water before it enters the deaerator, and for low pressure steam to heat water inside the deaerator, which improves overall boiler efficiency. Heat can be recovered from boiler blowdown by using a heat exchanger to preheat boiler makeup water. Additionally, changing from manual blowdown control to automatic control can reduce a boiler's energy use by 2 – 5 percent and reduce blowdown water losses by up to 20 percent.[1200]

The measure is applicable to commercial applications, commercial HVAC including multifamily buildings, low pressure applications, medium pressure industrial applications and high pressure applications. It was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as a functional steam boiler with a blowdown heat recovery system that increases the heat recovery and boiler efficiencies in comparison to the baseline case. New systems are not eligible for this measure.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an existing steam boiler system with a deaerator where no blowdown heat is recovered

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years; capped at the measure life of a steam boiler.[1201]

DEEMED MEASURE COST

If known, the actual material and labor cost of installation should be used. If unknown, the cost of this measure is estimated to be $1.4/kBtu/hr[1202] per boiler. This cost includes material and labor for installing boiler blowndown heat recovery systems (i.e - storage tanks, pipes and pumps).

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

N/A

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

Natural gas savings are calculated by estimating the amount of blowdown net heat flow. Savings are calculated from the enthalpy difference between the make-up water and the blowndown temperature.

$$\Delta\text{Therms} = \frac{\text{BFR} \times (\text{H}_\text{B} - \text{H}_\text{w})}{\text{n}_\text{boiler} \times 100{,}000} \times \text{SF}$$

Where:

BFR = Boiler Blowdown flow rate in lb/year. The calculated blowndown flow rate is in turn used to calculate natural gas savings. Boiler heat recovery systems vary widely between manufacturers and facilities.

$$\text{BFR} = \text{Annual}_\text{usage} \times \%\text{BD}$$

$\text{Annual}_\text{usage}$ = The annual steam usage in lbm/year.

= Actual or if unknown:

$$\text{Annual}_\text{usage} = \left[\frac{\text{Hours} \times \text{Capacity}}{[(\text{H}_\text{S} - \text{H}_\text{B})(1 - \%_\text{make-up}) + (\text{H}_\text{S} - \text{H}_\text{w})(\%_\text{make-up})]}\right]$$

Capacity = Boiler input capacity in btu/hr.

$\%_\text{make-up}$ = Percentage of make-up water

= 20%[1203] or actual if known.

If space heating:

Hours = Equivalent Full Load Hours of heating in Existing Buildings; provided in section 4.4 HVAC End Use.

If process:

Hours = $\text{Annual Hours} \times \text{UF}$

DEEMED O&M COST ADJUSTMENT CALCULATION

Maintenance personnel should complete annual or semi-annual maintenance inspections of the condensate return system for its optimal performance. The O&M cost shall be included in cost-effectiveness calculations. It is recommended to service the following components to maintain the system's proper operation: pumps, ensure periodic lubrication for motors, in accordance with the motor manufacturer's guidelines. Strainers, traps should also be included as an O&M consideration. A custom calculation should be used as necessary.

4.4.64 Steam Vent Condensers

DESCRIPTION

According to the Department of Energy[6], vent condensers can be used with condensate systems to reduce the amount of energy needed to maintain steam temperatures. When flash steam is being vented to atmosphere, it carries with it the energy required to heat water to steam temperature, eventually wasted. Another condenser in the form of a heat exchanger attached to the condensate recovery system will allow this energy to remain within the system and thus reduce the energy needed to heat the condensate back up to the steam pressure necessary for operation. The recovered flash steam will also be distilled after eventually condensing and require less outside water to be introduced to the system. This improves longterm performance by reducing the need for undistilled feed water that has a higher concentration of heavy particulates that scale inside boilers and absorbe heat, making the boilers less efficient.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure requires that a heat exchanger be installed with capability to condense flash steam and return distilled water to the condensate tank.

DEFINITION OF BASELINE EQUIPMENT

This measure requires that a building must be equipped with steam boilers and a condensate recovery tank with flash steam venting in use. This also requires the building to be equipped with multiple pressure loads beyond heating applications and work within the parameters of fully efficient steam sytems already. Steam equipment must meet baseline efficiency standards for boilers and condensate recovery, as well as working order steam traps.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure of life is assumed to be 20 years.[1217]

DEEMED MEASURE COST

The measure cost of a vent condenser must be custom to the type installed and associated equipment necessary.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

Natural gas energy savings are calculated for steam vent condensers per the equations given below.

$$\Delta Therms = \frac{Vent_{rate} \times (H_s - H_w) \times hours}{n_{boiler} \times 100{,}000} \; X\; SF$$

Where:

$$Vent_{rate} = Condensate_{load} \times \%_{flash\ Steam}$$

$Vent_{rate}$ = The rate at which steam passes through the vent (lb/hr)

$Condensate_{load}$ = Estimated condensate load based on pipe size[1218] (lb/hr)

$$Condensate_{load} = 114[Pipe_{size}]^{2.38}$$

$Pipe_{size}$ = Diameter of vent pipe (inches)

%FlashSteam = Percentage of flash steam (%)

System Type	Flash Steam percentage[1219] (°F)
5 psi Steam (low pressure)	1.6%
15 psi Steam (low pressure)	3.9%
40 psi Steam (low pressure)	7.8%
65 psi Steam (high pressure)	10.5%
100 psi Steam (high pressure)	13.3%
150 psi Steam (high pressure)	16.3%

If space heating:

Hours = = Equivalent Full Load Hours of heating in Existing Buildings; provided in section 4.4 HVAC End Use.

If process:

Hours = $= \text{Annual Hours} \times \text{UF}$

Annual Hours = Annual operating hours of the facility

[1218] Design of Fluid Systems Hook-ups by Spirax Sarco (1992) Page 37. Table 11 Minimum Dimensions of Flash Vessels. Max condensate quantity and Inlet and Flash Steam Outlet size were plotted against each other. Constants for a power trendline equation were obtained as a result. An oversize factor of 0.5 was applied to the maximum condensate load to account for times when exact pipe sizes cannot be obtained, and the next available pipe size needs to be selected.

4.4.65 Computer Room Air Conditioner (CRAC)

DESCRIPTION

Computer Room Air Conditioning (CRAC) Units are installed to meet cooling requirements for computers, servers, and other electronic components. This measure promotes the installation of CRAC units by exploring the space cooling savings potential for the replacement or new commissioning of a computer room air conditioner.[1224]

This measure could apply to the replacing of an existing functional unit, an existing unit at the end of its useful life or the installation of a new unit in a new or existing building.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is assumed to be a CRAC Unit in the equipment categories expressed in Tables 1 and 2 that exceeds the energy efficiency requirements as prescribed by the program. The equipment must be categorized as either floor or ceiling mounted.

The equipment must possess a net sensible cooling capacity less than 760,000 Btu/h for equipment classified as upflow non-ducted or horizontal flow. Equipment that is classified as Downflow or upflow ducted shall not exceed the net sensible cooling capacity of 930,000 Btu/h.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be a standard-efficiency air- cooled, air- cooled with a fluid economizer, water-cooled, water-cooled with a fluid economizer, glycol-cooled, or glycol-cooled with a fluid economizer air conditioner that meets the Code energy efficiency requirements (IECC or Code of Federal Regulations whichever is higher) in effect on the date of equipment purchase (if date is unknown, assume current Code minimum).

In order for this characterization to apply, the baseline equipment is assumed to meet the efficiency requirements within the code in effect on the date of the building permit. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 15 years.[1225]

DEEMED MEASURE COST

$750 per ton incremental costs may be assumed. Actual CRAC costs vary widely in practice.[1226]

[1224] "State of Minnesota Technical Reference Manual for Energy Conservation Improvement Programs" January 31st, 2024 https://mn.gov/commerce-stat/trm/releases/4.1.pdf#page=319&zoom=100,93,96

LOADSHAPE

Loadshape is determined by the constant power draw by the equipment;

Loadshape C53 – Flat

COINCIDENCE FACTOR

The coincidence factor is determined by the constant power draw by the server room; the summer peak coincidence factor for the equipment is assumed to be 1.0

CFPJM = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (Size * LF * EFLH * (1/nsenCOPBASE - 1/nsenCOPEE)) / 0.2843$$

Where:

Size = the nominal cooling capacity rating of the energy efficient chiller (tons). 1 ton = 12,000 Btu/h

= Actual

LF = Cooling load factor

= 0.65[1227]

0.2843 = conversion factor (0.2843 tons/ kWh)

NSenCOPBASE = minimum rated Net Sensible Coefficient of Performance (NSenCOP)[1228]. See Tables 1 and 2.

NSenCOPEE = rated Net Sensible Coefficient of Performance (NSenCOP) for the energy efficient CRAC

= Actual

EFLH = Equivalent full load hour of cooling

= 8,760 hours

[1227] ASHRAE Technical Support Document, 4.2.3.2 "Estimate the Average Computer Server Heat Load", page 4-15.
[1228] CRAC efficiencies are not represented by any other efficiency measurements such as IEER, EER, SEER, IPLV, or COP. Under AHRI Standard 1360-2017 (1361-2017), Net Sensible Cooling Capacity (not Total Cooling Capacity) is used to calculate a Net Sensible Coefficient of Performance.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (Size * LF * CF * (1/nsenCOPBASE - 1/nsenCOPEE)) / 0.2843$$

Where:

CF = Coincidence factor

= 1.0

Other factors as defined above

For example, an air-cooled upflow non-ducted CRAC is installed with a rated NsenCOP of 3.00, and net sensible cooling capacity of 60,000 Btu/h (5 tons). From Table 1, the baseline NsenCOP efficiency equals 2.16.

$$\Delta kWh = (Size * LF * EFLH * (1/nsenCOPBASE - 1/nsenCOPEE)) / 0.2843$$
$$= (5\ tons * 0.65 * 8760hrs * (1/2.16 - 1/3.0)) / 0.2843\ tons/kWh$$
$$= \mathbf{12,982\ kwh}$$
$$\Delta kW = (Size * LF * CF * (1/nsenCOPBASE - 1/nsenCOPEE)) / 0.284\ ton/kW$$
$$= (5\ tons * 0.65 * 1 * (1/2.16 - 1/3.0) / 0.2843\ kW/ton$$
$$= \mathbf{1.48\ Kw}$$

[1] For downflow and upflow-ducted CRACs, the NSCC measured per AHRI 1360–2017 and the latest update to the standard, AHRI 1360–2022, is higher than the NSCC measured per the current Federal test procedure (which references ANSI/ASHRAE 127–2007). Therefore, to ensure equipment currently covered by Federal standards is not removed from coverage, DOE translated the currently applicable upper capacity limit for these classes (760,000 Btu/h) to NSCC as measured per AHRI 1360–2017 and AHRI 1360–2022, resulting in a crosswalked upper capacity boundary of 930,000 Btu/h. Consequently, DOE has used 930,000 Btu/h as the translated upper capacity limit for downflow and upflow-ducted CRACs in the analysis presented in this notice. For up-flow non-ducted CRACs, because there is no change in return air temperature conditions between ANSI/ASHRAE 127–2007 and AHRI 1360–2022, the capacity boundaries in ASHRAE Standard 90.1–2019 remain the same as those specified in the current Federal standards, and DOE correspondingly retains the current capacity boundaries. For horizontal-flow CRACs, DOE does not currently prescribe standards; therefore, a crosswalk of current capacity boundaries is not applicable. See section III.C.5 of this final rule for further discussion of DOE's crosswalk analysis of capacity boundaries for CRACs.

[2] Btu/h refers to "British thermal units per hour."

[3] The amended standard for this equipment class is of equivalent stringency to the currently applicable Federal standard—the adopted level is a translation from the current metric (SCOP) to the adopted metric (NSenCOP) and aligns with the corresponding level in ASHRAE Standard 90.1.

4.4.66 Steam Leak Repair

DESCRIPTION

The measure applies to the repair of steam leaks that allow steam to escape the steam distribution system. Steam leaks result in the loss of both latent heat and kinetic energy. The Steam Leak Repair measure is applicable to commercial applications, commercial HVAC (low pressure steam) including multifamily buildings, low-pressure, medium-pressure and high-pressure industrial applications. The measure is to be used when metered data is not available. Additional methods for estimating steam leak such as the plume length method may take precedence over this approach, especially for system operating pressures of 115 psig and higher.

Steam leaks that are found in steam traps must be addressed through measure 4.4.16 Steam Trap Replacement or Repair.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Customer must repair steam leak by valve packing replacement, gasket replacement, long-term epoxy wrapping, or by welding when appropriate.

DEFINITION OF BASELINE EQUIPMENT

The baseline criterion is an individual steam leak in a low, medium or high-pressure steam system. No minimum leak rate is required. Any leak can be repaired or replaced.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

6 years for steam traps or other mechanical components.[1231] Welded repairs should use a default assumption of 18 years.[1232]

DEEMED MEASURE COST

The cost for this measure can vary considerably depending on where the steam leak occurs and the work / parts required to repair it. Use custom costs where costs are not provided; otherwise use $337[1233] /(lb/hr) of steam leak.

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

N/A

[1231] CLEAResult "Steam Traps Revision #1", August 2011. Primary studies used to prepare the source paper include Enbridge Steam Trap Survey, KW Engineering Steam Trap Survey, Enbridge Steam Saver Program 2005, Armstrong Steam Trap Survey, DOE Federal Energy Management Program Steam Trap Performance Assessment, Oak Ridge National Laboratory Steam System Survey Guide, KEMA Evaluation of PG&E's Steam Trap Program, Sept. 2007. Communication with vendors suggested an inverted bucket steam trap life typically in the range of 5 - 7 years, float and thermostatic traps 4- 6 years, float and thermodynamic disc traps of 1 - 3 years. Cost does not include installation.

[1232] Mazel, R E, and Anokhov, A E. Increasing the reliability of steam pipe welded joints. United States: Sov. Power Eng. (Engl. Transl.); (United States), Vol. 11:8; August 1982. Operating experience with thermal power plants shows that butt welds of steam pipes made of Cr-Mo-V steels have a satisfactory reliability over the course of 150,000 hours of operation.

[1233] Measure costs are based on data from seven steam leak projects provided by Franklin Energy Services.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS[1234]

$$\Delta Therm = \frac{S_a \times \left(H_v + H_s * (T_1 - T_{source})\right) * Hours}{100000 * \eta_B}$$

Where:

For Low Pressure Steam used in space heating applications (5psig or lower):

$$\mathrm{S_a} = \text{Steam loss per leak lb/hr} = \frac{1519.3 * P_1 * D_1 * [\left(\frac{1}{T_1} * \frac{\gamma}{\gamma - 1}\right) * (\left(\frac{P_2}{P_1} * \frac{2}{\gamma}\right) - \left(\frac{P_2}{P_1} * \frac{\gamma + 1}{\gamma}\right)]}{2}$$

For all other steam systems and applications, use the following equation:

Sa = $24.24 * P_1 * D_1^2 * A * FF$

Where:

γ = heat capacity ratio

= $5.071 * 10^{-4} * P_1 + 1.332$

P_1 = Average Steam Inlet Pressure (psia)

P_2 = Average Steam Outlet Pressure. If unknown assume 14.696 psia.

D_1 = Effective diameter of the leak. If unknown use D1 = 0.08 in[1235]

A = 50%[1236], all steam systems. This factor accounts for reduction in the maximum theoretical steam flow to the average steam flow (the Enbridge factor).

H_v = Enthalpy of Vaporization in Btu/lb if unknown see Table below.

H_s = Specific Heat of Water, (Btu/(lbm * ºR))

= 1.001

T_1 = Temperature of Saturated Steam (°R) = $507.89 * P_1^{0.0962}$, if unknown see Table below.

T_{source} = Temperature at the source, if unknown see Table below:

[1234] See "Derivation of Equation for Subsonic Compressible Flow through an Orifice and Supporting Calculations for Illinois TRM Steam Trap Measure" paper for more information.

[1235] Diameter based on "Rule of Thumb for Estimating Energy Cost Savings from the Department of Energy Lean & Energy Toolkit: Appendix C | US EPA". High-pressure steam leaks (125 pounds per square inch gauge (psig) repairs are expected to save from $150 to $500 per leak per shift per year. The Department of Energy uses a natural Gas cost of $0.35 per one hundred cubic feet (ccf). With an 80% boiler efficiency; the leak size is estimated at 342 CCF or 331 therms per leak per shift per year using the lower end of the cost savings. There are about 2,760 working hours per shift per year, which results in 0.17 therms per leak per hour. Utilizing the equation of steam loss per leaking trap from measures 4.4.16 steam trap replacement, the equivalent of 0.17 therm per leak per hour is a 0.08 orifice size. The analysis was also made for low-pressure steam leaks defined as 15 psig, costing $30 to $100 per leak per shift year. The same orifice size was obtained.

[1236] Enbridge adjustment factor used as referenced in CLEAResult "Work Paper Steam Traps Revision #2" Revision 3 dated March 2, 2012 and DOE Federal Energy Management Program Steam Trap Performance Assessment.

Steam System	Hv (btu/lb)[1237]	T1 (°R)	Ts (°R)[1238]	Average Inlet Pressure (psig)[1239]
Commercial Dry Cleaners	890	789.060	513.67	82.8
Multifamily LPS	951	672.103	513.67	3.7
Multifamily LPS ≥ 5 psig and < 15 psig	951	694.581	513.67	11.2
Commercial LPS Space Heat < 15 psig	951	694.581	513.67	11.2
Industrial or Process Low Pressure, < 15 psig	951	694.581	513.67	11.2
Medium Pressure > 15 psig < 30 psig	944	706.036	513.67	16
Medium Pressure ≥ 30 < 75 psig	915	755.079	513.67	47
High Pressure ≥ 75 < 125 psig	880	802.160	513.67	101
High Pressure ≥ 125 < 175 psig	859	827.918	513.67	146
High Pressure ≥ 175 < 250 psig	837	852.076	513.67	202
High Pressure ≥ 250 < 300 psig	816	872.652	513.67	263

Hours = Hours of plant operation

= Actual, if unknown, use default hours provided below:

Steam System	Zone (where applicable)	Hours/Yr[1240]
Commercial Dry Cleaners	All Climate Zones	2,425
Industrial/Process Low Pressure: psig < 15		8,282
Medium Pressure: 15 ≤ psig < 30		8,282
Medium Pressure: 30 ≤ psig < 75		8,282
High Pressure: 75 ≤ psig < 125		8,282
High Pressure: 125 ≤ psig < 175		8,282
High Pressure: 175 ≤ psig < 250		8,282
High Pressure: 250 ≤ psig < 300		8,282

4.4.67 CRAC/CRAH Electronically Commutated Plug Fans

DESCRIPTION

This measure requires the installation of Electronically Commutated (EC) plug fans in Computer Room Air Conditioner (CRAC) and/or Computer Room Air Handler (CRAH) units. The EC plug fans will be replacing conventional, belt-driven fans. Installing any mechanism that could potentially modify the airflow of the supply fan on a DX system has potential to freeze the coil. Installation of any ECM on a CRAC unit should be verified with the manufacturer.

This measure was developed to be applicable to the following program types: TOS and ER. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The ECM application involves the replacement of existing CRAC or CRAH fans with an EC plug nDefinition of Baseline Equipment

The baseline criteria is a CRAC/CRAH unit with centrifugal, belt-driven fans powered by three-phase AC motors.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

15 years[1242]

DEEMED MEASURE COST

If known, actual equipment and labor costs should be used.

If unknown, assume an incremental cost of $1,700 per fan[1243].

LOADSHAPE

Loadshape C53 – Flat

COINCIDENCE FACTOR

CF = 1.0

[1242] ASHRAE Standard 90.1-2010 Equipment Final Rule Technical Support Document Chapter 6, Life-Cycle Cost and Payback Period Analysis. Lifetime is assumed to be the same as that of the CRAC/CRAH system that the fan is attached to, see 4.4.65 Computer Room Air Conditioner (CRAC)

[1243] Estimated average cost of selecting an EC fan option over a baseline fan option when purchasing a new CRAC unit. This comes from a Colorado custom rebate project, please see 'CO-Rates-and-Reg-DSM-Sata-Center-Efficiency-Deemed-Savings-2016.pdf

Algorithm

CALCULATION OF ENERGY SAVINGS

Default savings for this measure are shown in the table below:

Location of Plug Fan	Annual Energy Savings (kWh/HP)	Peak Demand Reduction (kWh/HP)
In Unit	1,390	0.1587
Underfloor	2,306	0.2633
If Unknown	1,848	0.2110

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \Delta Fan\ Power * \left[HOU_{Fan} + \left(\frac{3{,}413}{12{,}000} * \eta_{cooling}\right) * HOU_{Fan} \right]$$

$$\Delta Fan\ Power = HP * (1 - CLF) * 0.746 * UF$$

$$CLF = \left(\frac{\eta_{base\ fan} * \eta_{base\ belt} * \eta_{base\ motor}}{\eta_{EC\ fan} * \eta_{EC\ drive} * \eta_{EC\ motor}}\right) - UDSF$$

Where:

$\Delta Fan\ Power$ = Fan power reduction (kW)[1235]

HOU_{Fan} = Annual hours of fan operation

$= 8{,}760$ Hours/year

3,413 = Btu to kWh conversion factor (Btu/kWh)

12,000 = Btu to ton (cooling) conversion factor (Btu/kWh)

$\eta_{cooling}$ = Efficiency of cooling system

$= 0.95$ KW/ton[1244]

HP = Fan power replaced (HP)

CLF = Comparison Load Factor. This term compares the baseline and EC system efficiencies and accounts for underfloor location (if applicable) to provide an estimate of the load on the EC system.[1235]

0.746 = kilowatt to hp conversion factor (KW/HP)

UF = % of CRAC/CRAH units in use

$= 83\%$[1245]

$\eta_{base\ fan}$ = Efficiency of baseline centrifugal, forward-curved fans

$= 53.81\%$[1246]

$\eta_{base\ belt}$ = Efficiency of baseline belt

$= 95\%$[1234]

4.4.68 Turbulators

DESCRIPTION

This measure relates to improving combustion efficiency by adding turbulators. Turbulators improve the boiler efficiency by reducing the stack temperature of single-pass horizontal return tubular (HRT) brick-set boilers and older two- and three-pass oil and natural-gas fuel firetube boilers.

In firetube boilers hot combustion gases pass through long, small-diameter tubes, where heat is transferred to water through the tube walls. Hot combustion gases enter the tubes in a turbulent flow regime, but within a few feet, laminar flow begins and a boundary level of cooler gas forms along the tuber walls. This layer serves as a barrier reducing heat transfer efficiency.

According to the Department of Energy[1249], turbulators consist of small baffles, angular metal strips, spiral blades or coil wire and typically installed on the last pass of the boiler tubes to break up the laminar boundary layer. Turbulators are added to increase the turbulence of the hot combustion gases and the convective heat transfer to the heat surface, increase boiler efficiency and reduce fuel costs. Turbulators are held in place with a spring lock and can be easily removed for tube brushing.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Efficient equipment is existing boiler with added turbulators. New boilers are not eligible for this measure.

DEFINITION OF BASELINE EQUIPMENT

Baseline is an existing vertical or horizontal firetube boiler providing steam or hot water for space heating loads.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

Adding turbulators does not extend the useful life of the boiler itself, the expected measure life is assumed to be the lower of remaining useful life of the boiler 8 years or 1/3rd of the boiler EUL (25yrs)[1250] .

DEEMED MEASURE COST

The cost of installing turbulators is $41 per tube or $0.40 per boiler input MBH[1251].

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

$$\Delta Therms = Capacity * Hours * UF * \left(\frac{nboiler + Savings\ Factor}{nboiler} - 1\right) * \frac{1}{100}$$

Where:

Capacity	= Nominal Heating Input Capacity Boiler Size (kBtu/hr) for existing unit
	= Custom Boiler input capacity in kBtu/hr
Hours	= If space heating, use EFLH, Equivalent Full Load hours for heating in Existing Buildings are provided in section 4.4 HVAC End Use
	= If process, = 8766 hours
UF	= Utilization Factor
	= 1 if space heating, since utilization factor already included in EFLH
	= If process, = 41.9%[1252]
nboiler[1253]	= Efficiency of the steam or hot water boiler
	= Actual, or if unknown:
	80% for hot water boilers
	79% for steam boilers
Savings Factor	= 3.25%[1254]
100	= constant to convert kbtu to therms

For example, turbulators installed in a Chicago 1,500 kBtu/hr steam boiler in an elementary school:

$$\Delta Therms = \frac{1{,}500 * 1{,}603 * 3.25\%}{100 * (80.7\% + 3.25\%)} = 930\ therms$$

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

[1252] Work Paper – Tune up for Boilers serving Space Heating and Process Load by Resource Solutions Group, January 2012

[1253] Federal Register, volume 74, Number 139, July 22, 2009 for boilers >300,000 Btu/hr

[1254] A reduction of 130°F was observed in the stack gas temperature in a manufacturing facility installing 150 turbulators into its firetube boiler. Because each 40°F reduction in the boiler flue gas temperature results in 1% boiler-efficiency improvement, the overall efficiency improved by 3.25%. Additionally, United States EPA, Climate Wise: Wise Rules for Industrial Efficiency, July 1998. The Wise Rules indicate savings range of 1-2% per 40°F reduction, so utilizing 1% is a conservative approach.

4.4.69 Waterless HVAC Condensate Trap

DESCRIPTION

Traditional, waterfilled P-traps are commonly installed on commercial HVAC condensate drainpipes to prevent air from leaking into or out of the HVAC system, but they rely on water remaining present in the curve of the trap at all times to prevent air infiltration. When traditional P-traps dry out in the winter or shoulder seasons due to the lack of condensate production, they allow air to enter or leave the HVAC system, resulting in energy loss as the replacement air must be conditioned. In commercial HVAC systems, this energy loss can become significant and lead to increased energy bills for building operators. A cost-effective means of reducing this energy loss is by replacing traditional P-traps with waterless HVAC condensate traps that seal using the HVAC system's air pressure instead of water, eliminating the concern of dried out P-traps.

Waterless HVAC condensate traps installed on commercial HVAC systems minimize air leakage from condensate drainpipes, while also minimizing the space needed for installation when compared to traditional P-traps. Laboratory testing[1255] of waterless HVAC condensate traps demonstrated that, across all tested models, pressure levels, and pipe diameters, air leakage rates consistently remained below 1 SCFM. Notably, 90% of the tests recorded leakage rates under 0.5 SCFM. These findings support that waterless HVAC condensate traps provide a highly effective alternative to traditional P-traps, significantly reducing air leakage in dry condensate drainpipes[1256]. These waterless condensate traps can function in both positive and negative pressure environments, and are adaptable to different system configurations, pressure ranges, and drainpipe connection types[1257]. When condensate forms, buoyancy lifts the float valve from the valve seat, allowing the condensate to drain properly

A variety of commercial packaged rooftop units (RTUs) HVAC units may qualify for this measure, including packaged rooftop units (RTUs), makeup air units (MAUs), and outdoor air handling units (AHUs).. The measure applies to commercial HVAC applications for retrofitting P-trap condensate traps with a properly sized waterless condensate trap with the exception of HVAC systems with a condensing gas-fired heating systems owing to condensate management in the heating season. It is assumed that the same HVAC system serves the building cooling and heating loads.

This measure was developed to be applicable to the following program types: TOS, RF, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is a waterless HVAC condensate trap designed for installation on a commercial HVAC system's condensate drainpipe.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment consists of a traditional, waterfilled P-trap, which is used as a condensate trap in commercial HVAC condensate drainpipes to prevent air leakage. This measure does not apply to existing P-traps that are sufficiently tall to hold condensate for several months.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

Specific data on the lifespan of HVAC condensate traps is limited, as their durability can be influenced by factors such as maintenance practices, water quality, and environmental conditions. The estimated useful life is assumed to be 5 years.

Algorithm

CALCULATION OF ENERGY SAVINGS

Any conditioned air leaked to the environment through a condensate drainpipe will need to be replaced by outdoor air that is conditioned, and the magnitude of the energy loss is driven by the temperature difference between the leaked air temperature and the outdoor air temperature. The leaked air temperature depends on the orientation of the cooling coil (with condensate drain) relative to the gas furnace heat exchanger and the HVAC supply fan. For systems where the cooling coil is upstream of the fan and the gas furnace, the leaked air temperature is estimated to be the same as the indoor air temperature at 75°F for all times the fan is running (heat and fan modes). For systems where the cooling coil and gas furnace are downstream of the fan, the leaked air temperature is estimated to be 120°F during heating mode and 75°F during fan only mode.

A leak would occur during the heating season if the depth of the standing water in the p-trap is not sufficient to withstand the pressure difference between the air handler and outdoors, which is more likely to occur during heating season due to evaporation of water in the trap and the lack of production of condensate during winter. The impact of a condensate drain leak during cooling season is unlikely during the summer when condensate is bring produced.

ELECTRIC ENERGY SAVINGS

Electric Energy Savings are only applicable if the heating system is electric. For gas-fired heating systems, please refer to the FOSSIL FUEL SAVINGS section for energy savings.

$$\Delta kWh = (kWh_{heating} + kWh_{fan})$$

Where:

$\Delta kWh_{heating}$ = heating energy saved in kWh during heating operation

ΔkWh_{fan} = heating energy saved in kWh during ventilation operation during heating season

$$kWh_{heating} = \frac{\dot{v} * 60 * EFLHheat * \rho * c_p * \Delta Theat * tons}{3{,}412 * \eta\text{Heat}}$$

[1258]The average material costs are based on an evaluation of commercial waterless HVAC condensate traps designed for positive/negative pressure systems with standard drainpipe diameters of 1.25", 1.5", and 2.0". Labor cost estimates are derived from 2025 RS Means data for PVC P-trap replacement in Springfield, IL.

$$kWh_{fan} = \frac{\dot{v} * 60 * EFLHfanheat * \rho * c_p * \Delta Tfan * tons}{3{,}412 * \eta\text{Heat}}$$

$\dot{v}$ = estimated leak rate for the HVAC system in CFM/ton[1259]. Use actual if known.

System Tonnage	External Static Pressure (in WC)	Leak Rate (cfm/ton)
Under20 tons	1"	0.6
	2"	0.9
	3"	1.0
20 - 50 tons	1"	0.6
	2"	0.8
	3"	1.0

60 = conversion from minutes to hour

$EFLH_{heat}$ = Equivalent Full Load Hours for heating in Existing Buildings are provided in section 4.4 HVAC End Use

ηHeat = Efficiency of electric heating system, as deemed from table below

System Type	Cooling Capacity of Equipment	Age of Equipment	HSPF Estimate	η (Effective COP Estimate) (HSPF/3.413)
Heat Pump[1260]	All	Before 2009	6.8	2.0
	< 65,000 Btu/h	2009 - 2017	7.7	2.3
		2017 on	8.2	2.40
	≥ 65,000 Btu/h and < 135,000 Btu/h	2010 on	11.3	3.3
	≥ 135,000 Btu/h and < 240,000 Btu/h	2010 on	10.9	3.2
	≥ 240,000 Btu/h and < 760,000 Btu/h	2010 on	10.9	3.2
Resistance	N/A	N/A	N/A	1

$EFLH_{fanheat}$ = Total Fan Run hours during heating season in fan mode when burner is off

= 0.5 * Total Fan Run Hours[1261]- $EFLH_{heat}$

= Assuming the heating season is from October to March

[1259] Rachael Collins, Theresa Pistochini, and Robert McMurry, "Laboratory Testing and Energy Saving Potential of Des Champs HVAC Air-Trap," UC Davis Western Cooling Efficiency Center, September 9, 2021

[1260] Minimum heating efficiency standards for heat pumps are sourced from the Code of Federal Standards for Small and Large Commercial Package Air Conditioning and Heating Equipment (Air Cooled), 10 CFR 431.97 with compliance dates of June 16, 2008; January 1, 2010; January 1, 2017; and January 1, 2018. As the first federal appliance standards for heating efficiency for commercial heat pumps went into effect in June 2008, assuming efficiency standards equivalent to residential heat pumps prior to that date.

[1261] Hours per year are estimated using the eQuest or OpenStudio models developed by VEIC, as the total number of hours the fans are operating for heating, cooling and ventilation for each building type. Assumes total fan run hours are divided equally between the heating and cooling seasons and that a traditional P-trap is fully dry during the heating season.

Total Fan Run Hours = Default hours are provided for HVAC applications which vary by HVAC application and building type in the following table[1262]. When available, actual hours should be used

ρ = density of the leaked air in lb/ft^3

= 0.08 (lb/ft3) at 1 atmosphere pressure and approximately 30-40°F[1263]

c_p = specific heat in BTU/(lb °F)

[1262] Ibid

[1263] Engineering ToolBox, (2003). Air - Density, Specific Weight and Thermal Expansion Coefficient at Varying Temperature and Constant Pressures. [online] Available at: https://www.engineeringtoolbox.com/air-density-specific-weight-d_600.html [Accessed April 2025].

= 0.24 (BTU/lb) at 1 atmosphere pressure and 32°F[1264]

$\Delta Theat$ = T_{heat} - $T_{Avg_Htg_OAT}$

= average difference between the leaked air temperature and the outside air temperature in °F for the hours in which fan and heating operates during the heating season

T_{heat} = Supply Air Temperature of the gas heating system.

= Use 120°F when cooling coil and furnace are downstream of fan. Use 75°F when cooling coil is upstream of fan and furnace. Use actual if known.

$T_{Avg_Htg_OAT}$ = Deemed average ambient air temperature over the heating season based on climate zone[1265]

Climate Zone	Heating Season Avg OA DBT
1 - Rockford	29.4 degF
2 - Chicago	34.2 degF
3 - Springfield	27.4 degF
4 - Belleville	38.4 degF
5 - Marion	31.4 degF

$\Delta Tfan$ = T_{fan} - $T_{Avg_Htg_OAT}$

T_{fan} = Return Air Temperature in the Air Handler. Use the indoor air temperature setpoint.

= 75°F or actual if known.

tons = Nominal rated tonnage of HVAC system. Use actual.

3,412 = conversion from Btu to kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

The annual gas heating energy saved per year is:

$$\Delta\text{Therms} = (\Delta\text{Therms}_{heating} + \Delta\text{Therms}_{fan})$$

$$\Delta Thermsheating = \frac{\dot{v} * 60 * EFLHheat * \rho * c_p * \Delta Theat * tons}{100{,}000 * \eta\text{Heat}}$$

$$\Delta Thermsfan = \frac{\dot{v} * 60 * EFLHfan * \rho * c_p * \Delta Tfan * tons}{100{,}000 * \eta\text{Heat}}$$

Where:

[1264] Engineering ToolBox, (2004). Air - Specific Heat at Constant Pressure and Varying Temperature. [online] Available at: https://www.engineeringtoolbox.com/air-specific-heat-capacity-d_705.html [Accessed April 2025]

[1265] BinMaker Pro weather data, based on average outdoor air temperatures over the hottest 5 calendar months. Outdoor average temperatures are assumed to be equivalent to the average temperatures of typical duct locations in: attics, basements, crawl spaces and outdoors. Additional research is recommended to verify actual average ambient temperatures in these areas; additional inputs may be recommended to identify the actual space type of the duct and create a lookup table based on space type and climate zone.

$\Delta Therms_{heating}$ = heating energy saved in therms during heating operation

$\Delta Therms_{fan}$ = heating energy saved in therms during ventilation operation in heating season

100,000 = conversion from Btu to therms

ηHeat = heating system efficiency

= custom, if unknown:

80% for hot water boilers[1266]

79% for steam boilers[1267]

83.2% for furnaces (including roof-top units)[1268]

Please see the previous section for a definition of parameters and guidance on default values to be used.

For example, a 30-ton RTU with the cooling coil and gas furnace downstream of the fan, rated for 3" WC external static pressure and with gas-fired heating in an elementary school in Chicago has a waterless condensate trap retrofitted in place of a p-trap:

Δtherms = ((1.1*60*1,603*0.08*0.24*(120-34.2)*30) + (1.1*60*279.5*0.08*0.24*(75-34.2)*30))/100,000*0.8

= (5,228,621.8 + 433,519.3)/(100,000 * 0.8)

= 70.8 therms

4.5. Lighting End Use

The commercial lighting measures use a standard set of variables for hours of use, waste heat factors, coincident factors and HVAC interaction effects. This table has been developed based on information provided by the various stakeholders. For ease of review, the table is included here and referenced in each measure.

The building characteristics of the eQuest models can be found in the reference table named "EFLH Building Descriptions Updated 2014-11-21.xlsx". The OpenStudio models are based upon the DOE Prototypes described in NREL's "U.S. Department of Energy Commercial Reference Building Models of the National Building Stock" and a calibration log file that documents all of the variations made to each model to get them calibrated is provided in "IL-Calibration-Log_2019-08-27.xlsx". Documents and all models are all available on the SharePoint site.

Note where a measure installation is within a building or application that does not fit with any of the defined building types below, the user should apply custom assumptions where it is reasonable to estimate them, else the building of best fit should be utilized.

In addition, deemed baseline fixture wattages (extracted from the 2026 Pennsylvania Technical Reference Manual, Appendix C, 'Lighting Audit & Design Tool for Commercial and Industrial Projects', accessed 07/2025) is provided in "Lighting Deemed Fixture Wattage.xls" within the 4.5 Lighting folder in the Reference Documents section of the Illinois TRM Sharepoint site.

Building/Space Type	Fixture Annual Operating Hours[1269]	Screw based bulb Annual Operating hours[1270]	Waste Heat Cooling Energy WHFe [1271]	Waste Heat Cooling Demand WHFd	Coinci-dence Factor CF[1272]	Waste Heat Gas Heating IFTherms[1273]	Waste Heat Electric Resistance Heating IFkWh[1274]	Waste Heat Electric Heat Pump Heating IFkWh	Model Source
Agriculture – Chicken Broilers[1275]	3,251	3,251	1.00	1.00	0.76	0.000	0.000	0.000	n/a

[1269]Fixtures hours of use are based upon schedule assumptions used in the eQuest models, except for those building types where Illinois based metering results provide a statistically valid estimate (currently: College, Elementary School, High School, Manufacturing, Low and Mid rise Office, Retail Department Store and Warehouse) or Grocery which is based on logging survey at 28 grocery stores in a Massachusetts DNV-GL "Lighting Hours of Use Study" report, April 12,2019. Miscellaneous is a weighted average of indoor spaces using the relative area of each building type in the region (CBECS).

[1270] Hours of use for screw based bulbs are derived from DEER 2008 by building type for cfls. Garage, exterior and multi-family common area values are from the Hours of Use Table in this document. Miscellaneous is an average of interior space values. Some building types are averaged when DEER has two values: these include office, restaurant and retail. Healthcare clinic uses the hospital value.

[1271] The Waste Heat Factor for Energy and is developed using EQuest models for various building types base on Chicago Illinois (closest to statewide average HDD and CDD). Exterior and garage values are 1, unknown is a weighted average of the other building types.

[1272]Coincident diversity factors are based on either combined IL evaluation results (College, Elementary School, High School, Manufacturing, Low and Mid rise Office, Retail Department Store and Warehouse), case lighting projects performed over several years by Michaels Energy in Illinois and other jurisdictions (Refrigerated and Freezer Cases), or based upon schedules defined in the eQuest models described (all others).

[1273] IFkWh Resistance value is developed using EQuest or OpenStudio models consistent with methodology for Waste Heat Factor for Energy.

[1274] Heat penalty assumptions are based on converting the IFkWh Resistance multiplier value in to IFtherms or IF kWhHeat Pump by applying relative heating system efficiencies. The gas efficiency was assumed to be 80% AFUE and the electric resistance is assumed to be 100%, for Heat Pump is assumed to be 2.3COP.

[1275] Agriculture lighting loadshapes, operational hours, and HVAC interactive factors were developed based on field experience and research material for the general agriculture, indoor agriculture, poultry and dairy commodities. Please see the excel files, 'General Agriculture Loadshape' and 'Indoor Agriculture Lighting Loadshape' on the 8760-calculation approach and for more

[1276] Based on Navigant verified value using 2014 Astronomical Applications Department, U.S. Naval Observatory data for ComEd's service territory. See Navigant Memorandum 'RE: LED Street Lighting Program Hours of Use for the ComEd and DCEO Programs. June 21, 2017'.

[1277] For closed refrigerated case lighting (open cases should use building type WHF), the value is 1.29 (calculated as (1 + (1.0 / 3.5))). Based on the assumption that all lighting in refrigerated cases is mechanically cooled, with a typical 3.5 COP refrigeration system efficiency, and assuming 100% of lighting heat needs to be mechanically cooled at time of summer peak. Assumes 3.5 COP for medium temp cases based on the average of standard reciprocating and discus compressor efficiencies with Saturated Suction Temperatures of 20°F and a condensing temperature of 90°F.

[1278] For closed freezer case lighting (open cases should use building type WHF), the value is 1.50 (calculated as (1 + (1.0 / 2.0))). Based on the assumption that all lighting in freezer cases is mechanically cooled, with a typical 2.0 COP freezer system efficiency, and assuming 100% of lighting needs to be mechanically cooled at time of summer peak. Assumes 2.0 COP for low temp cases based on the average of standard reciprocating and discus compressor efficiencies with Saturated Suction Temperatures of -20°F and a condensing temperature of 90°F.

Annual Operating Hours – Spaces with Lighting Controls

For spaces where occupancy or daylight sensors are known to be already installed, the user should adjust the Annual Operating Hours using the formula below. For v9.0, the TAC agreed that if current state is unknown by the implementer, then subsequent evaluation should assume the space does not have lighting controls. Over 2021 program year, this should be evaluated and the TAC will determine if a different unknown assumption should be used from V10 on.

Sensor Controlled Hours = Annual Operating Hours * (1- ESF)

Where:

Annual Operating Hours = Average hours of use per year for specific space type, provided in the Reference Table above.

ESF = Energy Savings factor (represents the percentage reduction to the operating Hours from the non-controlled baseline lighting system),

Table from Measure 4.5.10 Lighting Controls:

Lighting Control Type	Energy Savings Factor[1279]
Fixture Measurement of Control savings through Networked Trending	Custom
Interior Occupancy Sensor (Switch, Wall, Fixture or Remote Mounted or Integrated in Fixture)	24% 37% with High End Trim
Interior Occupancy Sensor configured as "Vacancy Sensor" (Switch, Wall, Fixture or Remote Mounted or Integrated in Fixture)	31% 44% with High End Trim
Interior Daylight Sensor (Wall, Fixture or Remote Mounted)	28% 41% with High End Trim
Interior Dual Occupancy & Daylight Sensor (Integrated of Fixture Mounted)	38% 51% with High End Trim
Interior Networked Luminaire-Level Lighting Controls	61%
Interior Networked Lighting Controls Only with No LLLCs	35%
Interior Networked Lighting Controls (Unknown or mixed LLLCs)	49%
Refrigerated Case Occupancy Sensor – Freezer and Cooler	27%
Exterior Occupancy Sensor	41%
No Lighting Control	0%

[1279] Interior controls % savings based except where noted on LBNL, Williams et al, "Lighting Controls in Commercial Buildings", 2012, p172. ESF for Vacancy Sensors is based on Papamichael, Konstantions, Bi-Level Switching in Office Spaces, California Lighting Technology Center, February 1,2010. See Figure 8 on page 10 for relevant study results. The study shows a 30% extra savings above a typical occupancy sensor; 24% * 1.3 = 31%.

ESF for Luminaire Level Lighting Controls, and 10% High End Trim adder are based upon review of:

Pacific Northwest National Laboratory, "Evaluation of Advanced Lighting Control Systems in a Working Office Environment", November 2018.

Schuetter et al., "Cree SmartCast Lighting Retrofit Demonstration: LED Fixtures and Controls for Advanced Holistic Lighting Solutions", September 2020 (expected).

DesignLights Consortium and NEEA, "Energy Savings from Networked Lighting Control and Luminaire-level Lighting Control Systems: 2020 Update", 2020 (expected).

Refrigerated Case occupancy sensors ESF is based on percentage of operating hours spent in low-power operation during vacant periods, found in SDG&E workpaper: WPSDGENRLG0027.

Exterior sensors are based upon data from "Application Assessment of Bi-Level LED Parking Lot Lighting" p6.

Note, if a program is installing lighting fixtures *and* controls, the interactive effect should be accounted for by assuming fixture watt savings for full annual operating hours, control savings on efficient fixture.

Exterior Lighting Hours – dusk to business close

Hours = (6.19 * Days) + (%Adj * Days)

Where:

6.19 = Average hours per day between dusk and midnight[1280]

Days = Days of business operation

= Actual

%Adj = Percent adjustment dependent on hour closing[1281]

Business closes at	4pm	5pm	6pm	7pm	8pm	9pm	10pm	11pm	12pm	1am	2am	3am
%Adj	-619%	-604%	-564%	-500%	-400%	-300%	-200%	-100%	0%	100%	200%	300%

For example a business open until 8pm, 260 days per year, would assume:

Hours = (6.19 * 260) + (-400% * 260) = 569.4 hours

[1280] Calculated using the eQuest model by finding the total number of hours of exterior lighting consumption between dusk and midnight and dividing by 365 (2261 / 365 = 6.19 hours per day).

[1281] See "IL TRM Ext Lighting.xlsx" for calculation.

4.5.1 Commercial ENERGY STAR Compact Fluorescent Lamp (CFL) – Retired 12/31/2018, Removed in v8

4.5.2 Linear Delamping

DESCRIPTION

This measure addresses the permanent removal of existing linear lamps from fixtures where spaces are overlit. Unused lamps, lamp holders, and ballasts must be permanently removed from the fixture disposed of in accordance with local regulations.

Customers are responsible for determining whether or not to use reflectors in combination with lamp removal in order to maintain adequate lighting levels. Lighting levels are expected to meet the Illuminating Engineering Society of North America (IESNA) recommended light levels. A pre-approval application is required for lamp removal projects.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Savings are defined on a per removed lamp basis. The retrofit wattage (efficient conditioned) is therefore assumed to be zero. The savings numbers provided below are for the straight lamp removal measures, as well as the lamp removal and install reflector measures. The lamp installed/retrofit is captured in another measure.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is the linear lamp being removed (default wattages provided below). Note, if the program does not allow for the lamp type to be known, then a T12:T8:T5:LED weighting of 7%:49%:5%:38% can be applied.[1282]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 11 years per DEER 2005.

DEEMED MEASURE COST

The actual capital cost for removal of lamps should be used if possible. Defaults are provided in the table below:

Measure Category	Value	Source
8-Foot Lamp Removal	$16.00	ComEd/KEMA regression[1283]
4-Foot Lamp Removal	$12.00	ICF Portfolio Plan
8-Foot Lamp Removal with reflector	$30.00	KEMA Assumption
4-Foot Lamp Removal with reflector	$25.00	KEMA Assumption
2-Foot or 3-Foot Removal	$12.35	KEMA Assumption
2-Foot or 3-Foot Removal with reflector	$25.70	KEMA Assumption

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the location type. Values are provided for each building type in the reference section below.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * Hours * WHFe$$

Where:

WattsBase = Assume wattage reduction of lamp removed

= Actual. If unknown assume:

	Wattage of lamp removed[1284]				Weighted average
	T12	T8	T5	LED	7% T12, 49% T8, 5% T5, 38% LED
8-ft	60.3	38.6	33.8	27.0	35.1
4-ft	33.7	19.4	17.0	13.6	17.9
3-ft	40	14.6	12.8	10.2	14.5
2-ft	28	9.8	8.6	6.9	9.8

WattsEE = 0

ISR = In Service Rate or the percentage of units rebated that get installed.

=100% if application form completed with sign off that equipment permanently removed and disposed of.

Hours = Average hours of use per year are provided in Reference Table in Section 4.5. If unknown use the Miscellaneous value.

WHFe = Waste heat factor for energy to account for cooling energy savings from efficient lighting are provided below for each building type in Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

[1284] Default wattage reduction is based on averaging the savings from moving from a 2 to 1, 3 to 2 and 4 to 3 lamp fixture, as provided in the Standard Performance Contract Procedures Manual: Appendix B: Table of Standard Fixture Wattages, Version 3.0, SCE, March 2004. An adjustment is made to the T8 delamped fixture to account for the significant increase in ballast factor. See 'Delamping calculation.xls' for details. Defaults for T5 and linear LED lamps estimated by applying typical relative efficacy of 70 lu/watt for T8s, 80 lu/watt for T5s and 100 lu/watt for LED lamps.

For example, delamping a 4 ft T8 fixture in a mid rise office building:

ΔkWh =((19.4 - 0)/1,000) * 1.0 * 4439 * 1.17

= 100.8 kWh

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}{}^{1285} = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * Hours * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

For example, delamping a 4 ft T8 fixture in a heat pump heated mid rise office building:

$\Delta kWh_{heatpenalty}$ =((19.4 - 0)/1,000) * 1.0 * 4439 * -0.104

=-9.0 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * WHFd * CF$$

Where:

WHFd = Waste heat factor for demand to account for cooling savings from efficient lighting in cooled buildings is provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value..

CF = Summer Peak Coincidence Factor for measure is provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value..

Other factors as defined above

For example, delamping a 4 ft T8 fixture in a mid rise office building:

ΔkW =((19.4 - 0)/1,000) * 1.0 * 1.62 * 0.6

= 0.019 kW

FOSSIL FUEL SAVINGS

Heating Penalty if fossil fuel heated building (or if heating fuel is unknown):

$$\Delta Therms^{1286} = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * Hours * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Interation Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

[1285] Negative value because this is an increase in heating consumption due to the efficient lighting.

[1286] Negative value because this is an increase in heating consumption due to the efficient lighting.

Other factors as defined above

For example, delamping a 4 ft T8 fixture in an office building:

ΔTherms =((19.4 - 0)/1,000) * 1.0 * 4439 * -0.016

=-1.4 therms

REVIEW DEADLINE: 1/1/2030

4.5.3 High Performance and Reduced Wattage T8 Fixtures and Lamps – Retired 12/31/2025, Removed in v14

4.5.4 LED Bulbs and Fixtures

DESCRIPTION

This characterization provides savings assumptions for a variety of LED lamps including Omnidirectional (e.g., A-Type lamps), Decorative (e.g., Globes and Torpedoes), Directional (PAR Lamps, Reflectors, MR16), Mogul (E39, EX39), TLEDs and fixtures including refrigerated case, recessed and outdoor/garage fixtures.

If the implementation strategy does not allow for the installation location to be known, 100% Commercial targeted programs and 0% Residential targeted programs for LED Fixtures, Mogul LEDs and TLEDs should be used.[1287]

This measure was developed to be applicable to the following program types: TOS, NC, EREP, DI, KITS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, new lamps and fixtures must meet ENERGY STAR[1288] specifications where appropriate (Downlights v1.0 Final Specification and Luminaires v2.2 Final Specification) or equivalent to the most recent version of ENERGY STAR specifications or be listed on the Design Lights Consortium Qualifying Product List.[1289]

DEFINITION OF BASELINE EQUIPMENT

The Standard Rx Program will assume a Time of Sale baseline for all one to one replacements, and early replacement for lighting redesign and early retirement for delamping.

For early replacement, the baseline is the existing fixture being replaced.

If the existing fixture is a T12: In July 14, 2012, Federal Standards were enacted that were expected to eliminate T-12s as an option for linear fluorescent fixtures. Through v3.0 of the TRM, it was assumed that the T-12 would no longer be baseline for retrofits from 1/1/2016. However, due to significant loopholes in the legislation, T-12 compliant product is still freely available and in Illinois T-12s continue to hold a significant share of the existing and replacement lamp market. From v8.0 on, a midlife adjustment is applied after the remaining useful life of the T12 fixture (calculated as 1/3 of the 40,000 hour ballast life/ hours). This assumes that T12 replacement lamps will continue to be available until then. See 'Early Replacement Measures with T12 baseline' section.

For Time of Sale, refer to the baseline tables at the end of this measure.

General Service Screw Based Lamps and ENERGY STAR fixtures: In 2012, Federal legislation stemming from the Energy Independence and Security Act of 2007 (EIAS) required all general-purpose light bulbs (defined as omni-directional or standard A-lamps) between 40 watts and 100 watts to have ~30% increased efficiency, essentially phasing out standard incandescent technology. In 2012, the 100 w lamp standards went in to effect followed by the 75 w lamp standards in 2013 and 60 w and 40 w lamps in 2014.

Additionally, an EISA backstop provision was included that would require replacement baseline lamps to meet an efficacy requirement of 45 lumens/watt or higher beginning on 1/1/2020.

However, in December 2019, DOE issued a final determination for General Service Incandescent Lamps (GSILs), finding that this more stringent standard was not economically justified. However, in May 2022 DOE reversed this decision by issuing a Final rule for both the broadened General Service Lamp definition as well as the implementation

[1287] Based on ComEd's Instant Discounts program CY2018, CY2019 and CY2020 (Rounds 1 and 2) Purchaser Survey analysis. See ComEd Instant Discounts Enduser Survey TRM Updates.xlsx. For Residential installations, hours of use assumptions from '5.5.6 LED Downlights' should be used for LED fixtures and '5.5.8 LED Screw Based Omnidirectional Bulbs' should be used for LED bulbs.

[1288] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[1289] ENERGY STAR Program Requirements Product Specifications for Lamps (Light Bulbs), version 2.1, effective January 2, 2017.

of the 45 lumen per watt backstop. DOE stated that it will use its enforcement discretion to minimize impacts on the supply chain and effectively allow companies to continue the manufacture and import of noncompliant bulbs through the remainder of 2022, and allow retailers to continue selling them with limited enforcement until July 2023.

As of 1/1/2026, no savings are claimed for screw based LED lamps or ENERGY STAR fixtures due to the EISA backstop unless installed via direct install programs. Direct Install programs where it can be shown that the LED is replacing working inefficient lighting should continue to use the existing inefficient lighting as baseline and assume a measure life of 2 years.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

For interior fixtures, and Mogul LEDs, the lifetime is the life of the product, at the reported operating hours (lamp life in hours divided by operating hours per year – see reference table "LED component Costs and Lifetime"), capped at 15 years (GDS Measure Life Report, June 2007).

For exterior fixtures, the lifetime is the life of the product, at the reported operating hours (lamp life in hours divided by operating hours per year), capped at 25 years. Default lifetimes are assumed to be 16 years for Dusk-to-Dawn (4303 hours) applications, or 25 years for Dusk-to-Business-Close Year Round (1609 hours) and Dusk-to-Business-Close Seasonal (<1000 hours).[1290]

For lamps and LED Downlight Fixtures with a baseline impacted by the EISA backstop as indicated in tables below the measure life is assumed to be two years for direct install programs.

For lamps not impacted by the EISA backstop, the lifetime is calculated as the rated lifetime of the product (actual if available, otherwise assume 20,000 hours for Omnidirectional, 17,000 hours for decorative and 25,000 for directional lamps based on average rated life of lamps on the ENERGY STAR Qualified Products list (accessed 6/16/2020)) divided by the reported operating hours, capped at 10 years.[1291]

DEEMED MEASURE COST

Wherever possible, actual incremental costs should be used. Refer to reference table “LED component Cost & Lifetime” for defaults.

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the location type. Values are provided for each building type in the reference section below.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((Watts_{base} - Watts_{EE})/1{,}000) * Hours * WHF_e * ISR * (1 - Leakage)$$

Where:

$Watts_{base}$ = Input wattage of the existing (for early replacement) or baseline system. Reference the "LED New and Baseline Assumptions" table for default values.

$Watts_{EE}$ = Actual wattage of LED purchased / installed. If unknown, use default provided below:

For ENERGY STAR rated lamps the following lumen equivalence tables should be used:[1292]

Omnidirectional Lamps - ENERGY STAR Minimum Luminous Efficacy = 80Lm/W for <90 CRI lamps and 70Lm/W for >=90 CRI lamps.

Minimum Lumens	Maximum Lumens	LED Wattage (WattsEE)	Baseline (WattsBase)	Delta Watts (WattsEE)	Impacted by EISA Backstop
120	309	4.0	25	21.0	No
310	399	4.0	25	21.0	Yes
400	749	6.6	29	22.4	Yes
750	899	9.6	43	33.4	Yes
900	1,399	13.1	53	39.9	Yes
1,400	1,999	16.0	72	56.0	Yes
2,000	2,999	21.8	150	128.2	Yes
3,000	3,299	28.9	200	171.1	Yes
3,300	3,999	28.9	200	171.1	No
4,000	5,000	35.7	300	264.3	No

[1292] See file "LED Lamp Updates 2021-06-09" for details on Guidehouse lamp wattage calculations based on equivalent baseline wattage and LED wattage of available ENERGY STAR product

Decorative Lamps - ENERGY STAR Minimum Luminous Efficacy = 65Lm/W for all lamps

Bulb Type	Minimum Lumens	Maximum Lumens	LED Wattage ($Watts_{EE}$)	Baseline ($Watts_{Base}$)	Delta Watts (WattsEE)	Impacted by EISA Backstop
Omni-Directional 3-Way	1,100	1,999	14.7	100	85.3	Yes
	2,000	2,700	22.6	150	127.4	Yes
Globe (medium and intermediate bases less than 750 lumens)	150	309	3.0	25	22	No
	310	349	3.0	25	22	Yes
	350	499	4.7	40	35.3	Yes
	500	574	5.7	60	54.3	Yes
	575	649	6.5	75	68.5	Yes
	650	1,000	8.2	100	91.8	Yes
Globe (candelabra bases less than 1050 lumens)	150	309	3.5	25	21.5	No
	310	349	3.5	25	21.5	Yes
	350	499	4.4	40	35.6	Yes
	500	574	5.5	60	54.5	Yes
Decorative (Shapes B, BA, C, CA, DC, F, G, medium and intermediate bases less than 750 lumens)	160	299	2.6	25	22.4	No
	300	309	4.3	40	35.7	No
	310	499	4.3	40	35.7	Yes
	500	800	5.8	60	54.2	Yes
Decorative (Shapes B, BA, C, CA, DC, F, G, T candelabra bases less than 1050 lumens)	120	159	1.5	15	13.5	No
	160	299	2.7	25	22.3	No
	300	309	4.2	40	35.8	No
	310	499	4.2	40	35.8	Yes
	500	650	5.5	60	54.5	Yes
Decorative (Shape ST)	250	309	6.5	40	33.5	No
	310	499	6.5	40	33.5	Yes
	500	999	8.8	60	51.2	Yes
	1000	1500	10.0	100	90.0	Yes
Decorative (Shape S)	50	75	1.0	11	10.0	No
	100	120	1.2	15	13.8	No
	120	309	2.25	25	22.8	No
	310	340	2.25	25	22.8	Yes

Directional Lamps - ENERGY STAR Minimum Luminous Efficacy = 70Lm/W for <90 CRI lamps and 61 Lm/W for >=90CRI lamps.

For Directional R, BR, ER, PAR, MR and MRX lamp types. Note the Center Beam Candle Power (CBCP) methodology described below the default table is the preferred methodology for PAR, MR and MRX lamps and should be used where data allows. Defaults for use when this information is not available are provided below:

Bulb Type	Minimum Lumens	Maximum Lumens	LED Wattage ($Watts_{EE}$)	Baseline ($Watts_{Base}$)	Delta Watts (WattsEE)	Impacted by EISA Backstop
Reflector lamp types with medium screw bases (PAR20, PAR30(S,L), PAR38, R40, etc.) w/ diameter >2.25" (*see exceptions below)	400	649	7.0	50	43	Yes
	650	899	10.7	75	64.3	Yes
	900	1,049	13.9	90	76.1	Yes
	1,050	1,199	13.8	100	86.2	Yes
	1,200	1,499	15.9	120	104.1	Yes
	1,500	1,999	18.9	150	131.1	Yes
	2,000	3,299	27.3	250	222.7	Yes
	3,300	4,200	27.3	250	222.7	No
Reflector lamp types with medium screw bases (PAR16, R14, R16, etc.) w/ diameter <2.25" (*see exceptions below)	280	309	4.6	35	30.4	No
	310	374	4.6	35	30.4	Yes
	375	600	6.4	50	43.6	Yes
*BR30, BR40, or ER40	650	949	9.3	65	55.7	Yes
	950	1,099	12.7	75	62.3	Yes
	1,100	1,399	14.4	85	70.6	Yes
	1,400	1,600	16.6	100	83.4	Yes
	1,601	1,800	22.2	120	97.8	Yes
*R20	450	524	6.0	40	34.0	Yes
	525	750	7.1	45	37.9	Yes
*MR16	250	309	3.8	20.0	16.2	No
	310	324	3.8	20.0	16.2	Yes
	325	369	4.8	25.0	20.2	Yes
	370	400	4.9	25.0	20.1	Yes

For PAR, MR, and MRX Lamps Types:

For these highly focused directional lamp types, it is necessary to have Center Beam Candle Power (CBCP) and beam angle measurements to accurately estimate the equivalent baseline wattage. The formula below is based on the Energy Star Center Beam Candle Power tool.[1293] If CBCP and beam angle information are not available or if the equation below returns a negative value (or undefined), use the manufacturer's recommended baseline wattage equivalent.[1294]

$$\text{Wattsbase} = 375.1 - 4.355(D) - \sqrt{227{,}800 - 937.9(D) - 0.9903(D^2) - 1479(BA) - 12.02(D * BA) + 14.69(BA^2) - 16{,}720 * \ln(CBCP)}$$

Where:

D = Bulb diameter (e.g. for PAR20 D = 20)

BA = Beam angle

[1293] ENERGY STAR Lamps Center Beam Intensity Benchmark Tool and Calculator

[1294] The Energy Star Center Beam Candle Power tool does not accurately model baseline wattages for lamps with certain bulb characteristic combinations – specifically for lamps with very high CBCP.

CBCP = Center beam candle power

The result of the equation above should be rounded DOWN to the nearest wattage established by Energy Star:

Diameter	Permitted Wattages
16	20, 35, 40, 45, 50, 60, 75
20	50
30S	40, 45, 50, 60, 75
30L	50, 75
38	40, 45, 50, 55, 60, 65, 75, 85, 90, 100, 120, 150, 250

Additional bulb types:

Bulb Type	Minimum Lumens	Maximum Lumens	LED Wattage ($Watts_{EE}$)	Baseline ($Watts_{Base}$)	Delta Watts (WattsEE)	Impacted by EISA Backstop
Dimmable Twist, Globe (less than 5" in diameter and > 749 lumens), candle (shapes B, BA, CA > 749 lumens), Candelabra Base Lamps (>1049 lumens), Intermediate Base Lamps (>749 lumens)	120	309	4.0	25	21.0	No
	310	399	4.0	25	21.0	Yes
	400	749	6.6	29	22.4	Yes
	750	899	9.6	43	33.4	Yes
	900	1,399	13.1	53	39.9	Yes
	1,400	1,999	16.0	72	56.0	Yes

Hours = Average hours of use per year are provided in the Reference Table in Section 4.5 for each building type. For Mogul LEDs, use fixture annual operating hours. If unknown, use the Miscellaneous value.

WHFe = Waste heat factor for energy to account for cooling energy savings from efficient lighting are provided below for each building type in the Referecne Table in Section 4.5. If unknown, use the Miscellaneous value.

ISR = In Service Rate -the percentage of units rebated that actually get installed.

=100% if application form completed with sign off that equipment is not placed into storage.[1295] If sign off form not completed, assume the following ISR assumptions, if program survey data is not available:

[1295] Illinois evaluation of PY1 through PY3 has not found that fixtures or lamps placed into storage to be a significant enough issue to warrant including an "In-Service Rate" when commercial customers complete an application form.

Type	Lifetime In Service Rate (ISR)[1296]
LED Bulbs	97.6%[1297]
Mogul LEDs	97.9%[1298]
LED Fixtures (Energy Star Fixtures)	97.9%[1299]
Efficiency Kits	92.4%[1300]

Type	Weighted Average 1st year In Service Rate (ISR)	2nd year Installations	3rd year Installations	Final Lifetime In Service Rate
TLEDs	83.1%[1301]	8.1%	6.8%	98.0%

Leakage = Adjustment to account for the percentage of program bulbs that move out (and in if deemed appropriate)[1302] of the Utility Jurisdiction.

Midstream (TOS) Lighting programs = Use deemed assumptions below:[1303]

ComEd: 0.31%

Ameren: 0%[1304]

All other programs = 0%

[1296] In Service Rates now represent the lifetime In Service Rates with the second and third year installations discounted by the Real Discount Rate of 0.46%. Lifetime ISR assumptions for efficiency kits are based upon Residenital direct mailed kits. For all other programs Tthe 98% Lifetime ISR assumption is based upon the standard CFL measure in the absence of any better reference. This value is based upon review of two evaluations:
'Nexus Market Research, RLW Analytics and GDS Associates study; "New England Residential Lighting Markdown Impact Evaluation, January 20, 2009' and 'KEMA Inc, Feb 2010, Final Evaluation Report:, Upstream Lighting Program, Volume 1.' This implies that only 2% of bulbs purchased are never installed. The second and third year installations are based upon Ameren analysis of the Californian KEMA study showing that 54% of future installs occur in year 2 and 46% in year 3.

[1297] Based on ComEd's Instant Discounts program CY2019 and CY2020 (Rounds 1 and 2) Purchaser Survey analysis. See ComEd Instant Discounts Enduser Survey TRM Updates.xlsx

[1298] Based on survey data from participants in AIC's 2022 Midstream Lighting channel. See AIC Midstream Lighting – Mogul ISR Calculations.xlsx

[1299] Based on ComEd's Instant Discounts program CY2019 and CY2020 (Rounds 1 and 2) Purchaser Survey analysis. See ComEd Instant Discounts Enduser Survey TRM Updates.xlsx

[1300] First year ISR is average ISR from CY2018, CY2019 and CY2020 ComEd Small Business Kit participant installation surveys. Please see file "SB Kits Survey Analysis TRMv10 Support.xlsx"

[1301] Based on ComEd's Instant Discounts program CY2019 and CY2020 (Rounds 1 and 2) Purchaser Survey analysis. See ComEd Instant Discounts Enduser Survey TRM Updates.xlsx

[1302] Leakage in is only appropriate to credit to IL utility program savings if it is reasonably expected that the IL utility program marketing efforts played an important role in influencing customer to purchase the light bulbs. Furthermore, consideration that such customers might be free riders should be addressed. If leakage in is assessed, efforts should be made to ensure no double counting of savings occurs if the evaluation is estimating both leakage in and spillover savings of light bulbs.

[1303] Leakage rate is based upon review of PY9-CY2021 evaluations from ComEd.

[1304] Per Ameren staff, all incentivized non-residential LED bulbs and fixtures are required to show proof of being an Ameren customer and thus the leakage is 0%.

Mid Life Baseline Adjustment

Early Replacement Measures with T12 Baseline

For early replacement measures replacing existing T12 fixtures the full savings (as calculated above in the Algorithm section) will be claimed for the remaining useful life of the T12 fixture. This should be calculated as follows:

RUL of existing T12 fixture = $(1/3 * 40{,}000)/Hours$

A savings adjustment should then be applied to the annual savings for the remainder of the measure life. The adjustment factor to be applied for each T12 installation is 57%.[1305]

For example, for an existing 68W T12 fixture in a college is replaced by a 3000 lumen LED 2x2 Recessed Light Fixture (25.4W), a mid life adjustment of 57% should be applied after (1/3 * 40000)/3395 = 3.9 years.

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}{}^{1306} = (((WattsBase - WattsEE)/1000) * ISR * Hours * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

For example, a 9W LED omnidirectional lamp, 450 lumens, is installed in a heat pump heated mid rise office and sign off form provided:

$\Delta kWh_{heatpenalty}$ = ((29-6.7)/1,000)*1.0*3088* -0.164

= - 11.3 kWh

DEFERRED INSTALLS

As presented above, if a sign off form is not completed the characterization assumes that a percentage of T-LED bulbs purchased are not installed until Year 2 and Year 3 (see ISR assumption above). The Illinois Technical Advisory Committee has determined the following methodology for calculating the savings of these future installs.

Year 1 (Purchase Year) installs:	Characterized using assumptions provided above or evaluated assumptions if available.
Year 2 and 3 installs:	Characterized using delta watts assumption and hours of use from the Install Year, i.e., the actual deemed (or evaluated if available) assumptions active in Year 2 and 3 should be applied. The NTG factor for the Purchase Year should be applied.

[1305] The appropriate T12 midlife adjustment factor was developed by the TAC Lighting Working Group. The results of a 2019 ComEd study provided survey response data on the planned replacement upon the burnout of a T12 ballast. This was adjusted by first year NTG to remove first year freeriders and therefore estimate what the non-freerider population would do at the end of T12 life. See "Linear Forecast Workbook_2020.xls" for information on calculation.

[1306] Negative value because this is an increase in heating consumption due to the efficient lighting.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = ((Watts_{base} - Watts_{EE})/1{,}000) * ISR * WHF_d * CF$$

Where:

WHFd = Waste Heat Factor for Demand to account for cooling savings from efficient lighting in cooled buildings is provided in Referecne Table in Section 4.5. If unknown, use the Miscellaneous value.

CF = Summer Peak Coincidence Factor for measure is provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

For example, a 9W LED omnidirectional lamp, 450 lumens, is installed in a mid rise office and sign off form provided:

ΔkW = ((29-6.7)/1,000)* 1.0*1.3*0.6
= 0.017 kW

FOSSIL FUEL SAVINGS

Heating Penalty if fossil fuel heated building (or if heating fuel is unknown):

$$\Delta Therms = ((Watts_{Base} - Watts_{EE})/1000) * ISR * Hours * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Integration Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficient lighting. Values are provided in the Referecne Table in Section 4.5. If unknown, use the Miscellaneous value.

For example, a 9W LED omnidirectional lamp, 450 lumens, is installed in a mid rise office and sign off form provided:

ΔTherms = ((29-6.7)/1,000)*1.0*3088* -0.016
= - 1.10 therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

For fixture measures, the individual component lifetimes and costs are provided in the reference table section below.[1307]

For lamps no O&M costs should be applied.

REFERENCE TABLES

LED Bulb Assumptions

Wherever possible, actual incremental costs should be used. If unavailable assume the following incremental costs:[1308]

[1307] See IL LED Lighting Systems TRM Reference Tables_2018.xlsx for breakdown of component cost assumptions.
[1308] Baseline and LED lamp costs are based on field data collected by CLEAResult and provided by ComEd. See ComEd Pricing Projections 06302016.xlsx for analysis. Given LED prices are expected to continue declining assumed costs should be reassessed on an annual basis and replaced with IL specific LED program information when available.

Bulb Type	Year	LED	Incandescent	Incremental Cost
Omnidirectional	2017	$3.21	$1.25	$1.96
	2018	$3.21		$1.96
	2019	$3.11		$1.86
	2020	$2.70		$1.45
Directional	2017	$6.24	$3.53	$2.71
	2018+	$5.18		$1.65
Decorative and Globe	2017	$3.50	$1.60	$1.90
	2018+	$3.40	$1.74	$1.66

LED Fixture Wattage, TOS Baseline and Incremental Cost Assumptions[1309]

LED Category	EE Measure Description	$Watts_{EE}$	Baseline Description	$Watts_{BASE}$	Incremental Cost
LED Downlight Fixtures* Impacted by EISA Backstop – apply 2 year measure life (or 8 years if IQ)	LED Recessed, Surface, Pendant Downlights	17.6	Baseline Recessed, Surface, Pendant Downlights	54.3	$27
LED Interior Directional	LED Track Lighting	12.2	Baseline Track Lighting	60.4	$59
	LED Wall-Wash Fixtures	8.3	Baseline Wall-Wash Fixtures	17.7	$59
LED Display Case[1310]	LED Display Case Light Fixture	4 per ft	Baseline Display Case Light Fixture	36.2 per ft	$11/ft
	LED Undercabinet Shelf-Mounted Task Light Fixtures	4 per ft	Baseline Undercabinet Shelf-Mounted Task Light Fixtures	36.2 per ft	$11/ft
	LED Refrigerated Case Light, Horizontal or Vertical	4 per ft	Baseline Refrigerated Case Light, Horizontal or Vertical (per foot)	15.2 per ft	$11/ft
	LED Freezer Case Light, Horizontal or Vertical	4 per ft	Baseline Freezer Case Light, Horizontal or Vertical (per foot)	18.7 per ft	$11/ft
LED Linear Replacement Lamps	T8 LED Replacement Lamp (TLED), < 1200 lumens	8.6	F17T8 Standard Lamp - 2 foot	15.0	$13

[1309] Watt assumptions for efficient measures are based upon the average wattage of each fixture type/lumen range from the Design Light Consortium (DLC) Qualifying Product Lists alongside past Efficiency Vermont projects and PGE refrigerated case study. Watt, lumen, lamp life, and ballast factor assumptions for baseline fixtures are based upon manufacturer specification sheets. Baseline cost data comes from lighting suppliers, past Efficiency Vermont projects, and professional judgment. Efficient cost data comes from 2012 DOE "Energy Savings Potential of Solid-State Lighting in General Illumination Applications", Table A.1. See "LED Lighting Systems TRM Reference Tables_2018.xlsx" for more information and specific product links.

[1310] LED Case Lighting is based on an average of DLC Horizontal and Vertical Lighting less than 80 W. This filter was intended to exclude vaportight fixtures from the average. The horizontal and vertical averages, provided by Guidehouse in 5/2020, were 4.1 W/ft and 3.7 W/ft, respectively.

LED Category	EE Measure Description	$Watts_{EE}$	Baseline Description	$Watts_{BASE}$	Incremental Cost

REVIEW DEADLINE: 1/1/2028

4.5.5 Commercial LED Exit Signs

DESCRIPTION

This measure characterizes the savings associated with installing a Light Emitting Diode (LED) exit sign in place of a fluorescent or incandescent exit sign in a Commercial building. Light Emitting Diode exit signs have a string of very small, typically red or green, glowing LEDs arranged in a circle or oval. The LEDs may also be arranged in a line on the side, top or bottom of the exit sign. LED exit signs provide the best balance of safety, low maintenance, and very low energy usage compared to other exit sign technologies.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is assumed to be an exit sign illuminated by LEDs.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be an existing fluorescent or incandescent model.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 5 years.[1312]

DEEMED MEASURE COST

The actual material and labor costs should be used if available. If actual costs are unavailable, assume a total installed cost of at $32.50.[1313]

LOADSHAPE

Loadshape C53 - Flat

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 100%.[1314]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((WattsBase - WattsEE) / 1{,}000) * HOURS * WHF_e$$

Where:

WattsBase = Actual wattage if known, if unknown assume the following:

Baseline Type	$Watts_{Base}$
Incandescent	35W[1315]
CFL (dual sided)	14W[1316]
CFL (single sided)	7W
Unknown	7W

[1312] Estimate of remaining life of existing unit being replaced.
[1313] Price includes new exit sign/fixture and installation. LED exit sign cost/unit is $22.50 based on the NYSERDA Deemed Savings Database and review of LED exit signs available as of April 2023, and assuming IL labor cost of 15 minutes @ $40/hr.
[1314] Assuming continuous operation of an LED exit sign, the Summer Peak Coincidence Factor is assumed to equal 1.0.
[1315] Based on review of available product.
[1316] Average CFL single sided (5W, 7W, 9W) from Appendix B 2013-14 Table of Standard Fixture Wattages.

WattsEE = Actual wattage if known, if unknown assume 2W for single sided or unknown type and 4W for dual sided[1317]

HOURS = Annual operating hours

= 8,766

WHF_e = Waste heat factor for energy to account for cooling energy savings from efficient lighting are provided for each building type in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

For example, replacing incandescent fixture in a mid rise office:

ΔkWH = ((35 – 2)/1,000) * 8766 * 1.17

= 338 kWh

Replacing single sided fluorescent fixture in a hospital with CAV economizer:

ΔkWH = ((7– 2)/1,000) * 8766 * 1.30

= 57.0 kWh

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}{}^{1318} = (((WattsBase - WattsEE)/1{,}000) * Hours * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

For example, replacing incandescent fixture in a heat pump heated mid rise office:

$\Delta kWh_{heatpenalty}$ = ((35 – 2)/1,000) * 8,766 * -0.104

= -30.1 kWh

Replacing single sided fluorescent fixture in a heat pump heated hospital with CAV economizer:

$\Delta kWh_{heatpenalty}$ = ((7 – 2)/1,000) * 8,766 * -0.099

= -4.3 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = ((WattsBase - WattsEE) / 1{,}000) * WHF_d * CF$$

Where:

WHF_d = Waste heat factor for demand to account for cooling savings from efficient lighting in cooled buildings is provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

CF = Summer Peak Coincidence Factor for measure

= 1.0

[1317] Average LED single sided (2W) from Appendix B 2013-14 Table of Standard Fixture Wattages.

[1318] Negative value because this is an increase in heating consumption due to the efficient lighting.

For example, replacing incandescent fixture in a mid rise office:

ΔkW = ((35 – 2)/1,000) * 1.36 * 1.0

= 0.045 kW

Replacing single sided fluorescent fixture in a hospital with CAV economizer:

ΔkW = ((7 – 2)/1,000) * 1.27 * 1.0

= 0.0064 kW

FOSSIL FUEL SAVINGS

Heating Penalty if natural gas heated building (or if heating fuel is unknown):

$$\Delta\text{therms} = ((WattsBase - WattsEE)/1000) * Hours * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Integration Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficient lighting. Values are provided in the Referecne Table in Section 4.5. If unknown, use the Miscellaneous value.

For example, replacing incandescent fixture in a mid rise office:

ΔTherms = ((35 – 2)/1,000) * 8,766 * -0.016

= -4.63 Therms

Replacing single sided fluorescent fixture in a hospital with CAV economizer:

ΔTherms = ((7 – 2)/1,000) * 8,766 * -0.009

= - 0.39 Therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

The annual O&M Cost Adjustment savings should be calculated using the following component costs and lifetimes.

	Baseline Measures	
Component	Cost	Life (yrs)
Lamp	$12.45[1319]	1.37 years[1320]

MEASURE CODE: CI-LTG-LEDE-V05-250101

REVIEW DEADLINE: 1/1/2028

[1319] Consistent with assumption for a Standard CFL bulb ($2.45) with an estimated labor cost of $10 (assuming $40/hour and a task time of 15 minutes).

[1320] Assumes a lamp life of 12,000 hours and 8766 run hours 12000/8766 = 1.37 years.

4.5.6 LED Traffic and Pedestrian Signals

DESCRIPTION

Traffic and pedestrian signals are retrofitted to be illuminated with light emitting diodes (LED) instead of incandescent lamps. Incentive applies for the replacement or retrofit of existing incandescent traffic signals with new LED traffic and pedestrian signal lamps. Each lamp can have no more than a maximum LED module wattage of 25. Incentives are not available for spare lights. Lights must be hardwired and single lamp replacements are not eligible, with the exception of pedestrian hand signals. Eligible lamps must meet the ENERGY STAR[1321] Traffic Signal Specification and the Institute for Transportation Engineers specification for traffic signals.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Refer to the Table titled 'Traffic Signals Technology Equivalencies' for efficient technology wattage and savings assumptions.

DEFINITION OF BASELINE EQUIPMENT

Refer to the Table titled 'Traffic Signals Technology Equivalencies' for baseline efficiencies and savings assumptions.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of an LED traffic signal is 10 years. The life in years is calculated by dividing 100,000 hrs (manufacturer's estimate) by the annual operating hours for the particular signal type and is capped at 10 years.[1322].

DEEMED MEASURE COST

The actual measure installation cost should be used (including material and labor).

LOADSHAPE

Loadshape C24 - Traffic Signal - Red Balls, always changing or flashing
Loadshape C25 - Traffic Signal - Red Balls, changing day, off night
Loadshape C26 - Traffic Signal - Green Balls, always changing
Loadshape C27 - Traffic Signal - Green Balls, changing day, off night
Loadshape C28 - Traffic Signal - Red Arrows
Loadshape C29 - Traffic Signal - Green Arrows
Loadshape C30 - Traffic Signal - Flashing Yellows
Loadshape C31 - Traffic Signal - "Hand" Don't Walk Signal
Loadshape C32 - Traffic Signal - "Man" Walk Signal
Loadshape C33 - Traffic Signal - Bi-Modal Walk/Don't Walk

COINCIDENCE FACTOR[1323]

The summer peak coincidence factor (CF) for this measure is dependent on lamp type as below:

Lamp Type	CF
Red Round, always changing or flashing	0.55
Red Arrows	0.90

[1321] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[1322] ACEEE, (1998) A Market Transformation Opportunity Assessment for LED Traffic Signals
[1323] Ibid.

Lamp Type	CF
Green Arrows	0.10
Yellow Arrows	0.03
Green Round, always changing or flashing	0.43
Flashing Yellow	0.50
Yellow Round, always changing	0.02
“Hand” Don’t Walk Signal	0.75
“Man” Walk Signal	0.21

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (W_{base} - W_{eff}) \, x \, HOURS \, / \, 1000$$

Where:

Wbase =The connected load of the baseline equipment

= see Table ‘Traffic Signals Technology Equivalencies’

Weff =The connected load of the baseline equipment

= see Table ‘Traffic Signals Technology Equivalencies’

HOURS = annual operating hours of the lamp

= see Table ‘Traffic Signals Technology Equivalencies’

1000 = conversion factor (W/kW)

For example, an 8 inch red, round signal:

ΔkWh = ((69 - 7) x 4818) / 1000

= 299 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (Wbase - Weff) \, x \, CF \, / \, 1000$$

Where:

Wbase =The connected load of the baseline equipment

= see Table ‘Traffic Signals Technology Equivalencies’

Weff =The connected load of the efficient equipment

= see Table ‘Traffic Signals Technology Equivalencies’

CF = Summer Peak Coincidence Factor for measure

For example, an 8 inch red, round signal:

ΔkW = ((69 – 7) x 0.55) / 1000

= 0.0341 kW

4.5.7 Lighting Power Density

DESCRIPTION

This measure relates to installation of efficient lighting systems in new construction or substantial renovation of commercial buildings excluding low rise (three stories or less) residential buildings. Substantial renovation is when two or more building systems are renovated, such as shell and heating, heating and lighting, etc. State Energy Code specifies a lighting power density level by building type for both the interior and the exterior. Either the Building Area Method or Space by Space method as defined in 2015, 2018, or 2021, depending on the IECC in effect on the date of the building permit (if unknown assume IECC 2021), can be used for calculating the Interior Lighting Power Density.[1326] The measure consists of a design that is more efficient (has a lower lighting power density in watts/square foot) than code requires. The IECC applies to both new construction and renovation.

This measure was developed to be applicable to the following program types: NC.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the lighting system must be more efficient than the baseline Energy Code lighting power density in watts/square foot for either the interior space or exterior space.

DEFINITION OF BASELINE EQUIPMENT

The baseline is assumed to be a lighting power density that meets the IECC in effect on the date of the building permit (if unknown assume IECC 2021).

Note, IECC 2021 became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

DEEMED CALCULATION FOR THIS MEASURE

Annual kWh Savings

$$\Delta kWh = (WSFbase - WSFeffic)/1000 * SF * Hours * WHF_e$$

Summer Coincident Peak kW Savings

$$\Delta kW = (WSFbase - WSFeffic)/1000 * SF * CF * WHF_d$$

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years.[1327]

DEEMED MEASURE COST

The actual incremental cost over a baseline system will be collected from the customer if possible or developed on a fixture by fixture basis.

LOADSHAPE

Loadshape C06 - Commercial Indoor Lighting

Loadshape C07 - Grocery/Conv. Store Indoor Lighting

Loadshape C08 - Hospital Indoor Lighting

[1326] Refer to the referenced code documents for specifics on calculating lighting power density using either the whole building method or the Space by Space method.

Loadshape C19 - Industrial Outdoor Lighting
Loadshape C20 - Commercial Outdoor Lighting

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the building type.

Algorithm

CALCULATION OF SAVINGS

ENERGY SAVINGS

$$\Delta kWh = (WSF_{base} - WSF_{effic}) / 1000 * SF * Hours * WHF_e$$

Where:

WSF_{base} = Baseline lighting watts per square foot or linear foot as determined by building or space type. Whole building analysis values are presented in the Reference Tables below.[1328]

WSF_{effic} = The actual installed lighting watts per square foot or linear foot.

SF = Provided by customer based on square footage of the building area applicable to the lighting design for new building.

Hours = Annual site-specific hours of operation of the lighting equipment collected from the customer. If not available, use building area type as provided in the Reference Table in Section 4.5, Fixture annual operating hours.

WHF_e = Waste Heat Factor for Energy to account for cooling savings from efficient lighting is as provided in the Reference Table in Section 4.5 by buidling type. If building is not cooled WHF_e is 1.

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}[1329] = (WSF_{base} - WSF_{effic}) / 1000 * SF * Hours * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected

[1328] See Reference Code documentation for additional information.
[1329] Negative value because this is an increase in heating consumption due to the efficient lighting.

by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (WSF_{base} - WSF_{effic})/1000 * SF * CF * WHF_d$$

Where:

WHF_d = Waste Heat Factor for Demand to account for cooling savings from efficient lighting in cooled buildings is as provided in the Reference Table in Section 4.5 by buidling type. If building is not cooled WHFd is 1.

CF = Summer Peak Coincidence Factor for measure is as provided in the Reference Table in Section 4.5 by buidling type. If the building type is unknown, use the Miscellaneous value of 0.66.

Other factors as defined above

FOSSIL FUEL SAVINGS

$$\Delta Therms = (WSF_{base} - WSF_{effic})/1000 * SF * Hours * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Integration Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficient lighting. This value is provided in the Reference Table in Section 4.5 by buidling type.

For smaller, hand-carried items	0.69

a. In cases where both a common space type and a building area specific space type are listed, the building area specific space type shall apply

b. A 'Facility for the Visually Impaired' is a facility that is licensed or will be licensed by local or state authorities for senior long-term care, adult daycare, senior support or people with special visual needs.

c. Where sleeping units are excluded from lighting power calculations by application of Section R405.1, neither the area of the sleeping units nor the wattage of lighting in the sleeping units is counted.

d. Where dwelling units are excluded from lighting power calculations by application of Section R405.1, neither the area of the dwelling units nor the wattage of lighting in the dwelling units is counted.

e. Class I facilities consist of professional facilities; and semiprofessional, collegiate, or club facilities with seating for 5,000 or more spectators.

f. Class II facilities consist of collegiate and semiprofessional facilities with seating for fewer than 5,000 spectators; club facilities with seating for between 2,000 and 5,000 spectators; and amateur league and high-school facilities with seating for more than 2,000 spectators.

g. Class III facilities consist of club, amateur league and high-school facilities with seating for 2,000 or fewer spectators.

h. Class IV facilities consist of elementary school and recreational facilities; and amateur league and high-school facilities without provision for spectators.

The exterior lighting design will be based on the building location and the applicable “Lighting Zone” as defined in IECC 2021 Table C405.5.2(1) which follows. This table is identical to IECC 2018 Table C405.4.2(1) and IECC 2021.

TABLE C405.5.2(1)
EXTERIOR LIGHTING ZONES

LIGHTING ZONE	DESCRIPTION
1	Developed areas of national parks, state parks, forest land, and rural areas
2	Areas predominantly consisting of residential zoning, neighborhood business districts, light industrial with limited nighttime use and residential mixed-use areas
3	All other areas not classified as lighting zone 1, 2 or 4
4	High-activity commercial districts in major metropolitan areas as designated by the local land use planning authority

The lighting power density savings will be based on reductions below the allowable design levels as specified in IECC 2015 Table C405.5.2(2) or 2018 Table C405.2.2(2) or IECC 2021 Table C405.52(2).

Allowable Design Levels from IECC 2015

TABLE C405.5.2(2)
INDIVIDUAL LIGHTING POWER ALLOWANCES FOR BUILDING EXTERIORS

		LIGHTING ZONES			
		Zone 1	Zone 2	Zone 3	Zone 4
Base Site Allowance (Base allowance is usable in tradable or nontradable surfaces.)		500 W	600 W	750 W	1300 W
Tradable Surfaces (Lighting power densities for uncovered parking areas, building grounds, building entrances and exits, canopies and overhangs and outdoor sales areas are tradable.)	**Uncovered Parking Areas**				
	Parking areas and drives	0.04 W/ft²	0.06 W/ft²	0.10 W/ft²	0.13 W/ft²
	Building Grounds				
	Walkways less than 10 feet wide	0.7 W/linear foot	0.7 W/linear foot	0.8 W/linear foot	1.0 W/linear foot
	Walkways 10 feet wide or greater, plaza areas special feature areas	0.14 W/ft²	0.14 W/ft²	0.16 W/ft²	0.2 W/ft²
	Stairways	0.75 W/ft²	1.0 W/ft²	1.0 W/ft²	1.0 W/ft²
	Pedestrian tunnels	0.15 W/ft²	0.15 W/ft²	0.2 W/ft²	0.3 W/ft²
	Building Entrances and Exits				
	Main entries	20 W/linear foot of door width	20 W/linear foot of door width	30 W/linear foot of door width	30 W/linear foot of door width
	Other doors	20 W/linear foot of door width	20 W/linear foot of door width	20 W/linear foot of door width	20 W/linear foot of door width
	Entry canopies	0.25 W/ft²	0.25 W/ft²	0.4 W/ft²	0.4 W/ft²
	Sales Canopies				
	Free-standing and attached	0.6 W/ft²	0.6 W/ft²	0.8 W/ft²	1.0 W/ft²
	Outdoor Sales				
	Open areas (including vehicle sales lots)	0.25 W/ft²	0.25 W/ft²	0.5 W/ft²	0.7 W/ft²
	Street frontage for vehicle sales lots in addition to "open area" allowance	No allowance	10 W/linear foot	10 W/linear foot	30 W/linear foot
Nontradable Surfaces (Lighting power density calculations for the following applications can be used only for the specific application and cannot be traded between surfaces or with other exterior lighting. The following allowances are in addition to any allowance otherwise permitted in the "Tradable Surfaces" section of this table.)	Building facades	No allowance	0.075 W/ft² of gross above-grade wall area	0.113 W/ft² of gross above-grade wall area	0.15 W/ft² of gross above-grade wall area
	Automated teller machines (ATM) and night depositories	270 W per location plus 90 W per additional ATM per location	270 W per location plus 90 W per additional ATM per location	270 W per location plus 90 W per additional ATM per location	270 W per location plus 90 W per additional ATM per location
	Entrances and gatehouse inspection stations at guarded facilities	0.75 W/ft² of covered and uncovered area	0.75 W/ft² of covered and uncovered area	0.75 W/ft² of covered and uncovered area	0.75 W/ft² of covered and uncovered area
	Loading areas for law enforcement, fire, ambulance and other emergency service vehicles	0.5 W/ft² of covered and uncovered area	0.5 W/ft² of covered and uncovered area	0.5 W/ft² of covered and uncovered area	0.5 W/ft² of covered and uncovered area
	Drive-up windows/doors	400 W per drive-through	400 W per drive-through	400 W per drive-through	400 W per drive-through
	Parking near 24-hour retail entrances	800 W per main entry	800 W per main entry	800 W per main entry	800 W per main entry

For SI: 1 foot = 304.8 mm, 1 watt per square foot = W/0.0929 m².
W = watts.

Allowable Design Levels from IECC 2018

Table C405.2.2(2)
Lighting Power Allowances for Building Exteriors

	Zone 0	Zone 1	Zone 2	Zone 3	Zone 4
Base Site Allowance (Base allowance may be used in tradable or nontradable surfaces.)					
	No allowance	350 W	400 W	500 W	900 W
Tradable Surfaces (*LPD* allowances for uncovered parking areas, *building* grounds, *building entrances*, exits and loading docks, canopies and overhangs, and outdoor sales areas may be traded.)					
Uncovered Parking Areas					
Parking areas and drives	No allowance	0.03 W/ft^2	0.04 W/ft^2	0.06 W/ft^2	0.08 W/ft^2
***Building* Grounds**					
Walkways/ramps less than 10 ft wide	No allowance	0.5 W/linear foot	0.5 W/linear foot	0.6 W/linear foot	0.7 W/linear foot
Walkways/ramps 10 ft wide or greater Plaza areas Special feature areas	No allowance	0.10 W/ft^2	0.10 W/ft^2	0.11 W/ft^2	0.14 W/ft^2
Dining areas	No allowance	0.65 W/ft^2	0.65 W/ft^2	0.75 W/ft^2	0.95 W/ft^2
Stairways	No allowance	0.6 W/ft^2	0.7 W/ft^2	0.7 W/ft^2	0.7 W/ft^2
Pedestrian tunnels	No allowance	0.12 W/ft^2	0.12 W/ft^2	0.14 W/ft^2	0.21 W/ft^2
Landscaping	No allowance	0.03 W/ft^2	0.04 W/ft^2	0.04 W/ft^2	0.04 W/ft^2
***Building Entrances*, Exits, and Loading Docks**					
Pedestrian and vehicular entrances and exits	No allowance	14 W/lin ft of opening	14 W/lin ft of opening	21 W/lin ft of opening	21 W/lin ft of opening
Entry canopies	No allowance	0.20 W/ft^2	0.25 W/ft^2	0.4 W/ft^2	0.4 W/ft^2
Loading docks	No allowance	0.35 W/ft^2	0.35 W/ft^2	0.35 W/ft^2	0.35 W/ft^2
Sales Canopies					
Free standing and attached	No allowance	0.4 W/ft^2	0.4 W/ft^2	0.6 W/ft^2	0.7 W/ft^2
Outdoor Sales					
Open areas (including vehicle sales lots)	No allowance	0.2 W/ft^2	0.2 W/ft^2	0.35 W/ft^2	0.5 W/ft^2
Street frontage for vehicle sales lots in addition to "open area" allowance	No allowance	No allowance	7 W/linear foot	7 W/linear foot	21 W/linear foot

TABLE C405.4.2(3)
INDIVIDUAL LIGHTING POWER ALLOWANCES FOR BUILDING EXTERIORS

LIGHTING ZONES				
	Zone 1	**Zone 2**	**Zone 3**	**Zone 4**
Building facades	No allowance	0.075 W/ft^2 of gross above-grade wall area	0.113 W/ft^2 of gross above-grade wall area	0.15 W/ft^2 of gross above-grade wall area
Automated teller machines (ATM) and night depositories	135 W per location plus 45 W per additional ATM per location			
Uncovered entrances and gatehouse inspection stations at guarded facilities	0.5 W/ft^2 of area			
Uncovered loading areas for law enforcement, fire, ambulance and other emergency service vehicles	0.35 W/ft^2 of area			
Drive-up windows and doors	200 W per drive through			
Parking near 24-hour retail entrances.	400 W per main entry			

For SI: For SI: 1 watt per square foot = W/0.0929 m^2.

W = watts.

Allowable Design Levels from IECC 2021

Open areas (including vehicle sales lots)	0.20 W/ft^2	0.20 W/ft^2	0.35 W/ft^2	0.50 W/ft^2
Street frontage for vehicle sales lots in addition to "open area" allowance	No allowance	7 W/linear foot	7 W/linear foot	21 W/linear foot

For SI: 1 foot = 304.8 mm, 1 watt per square foot = W/0.0929 m^2.
W = watts.

TABLE C405.5.2(3)
INDIVIDUAL LIGHTING POWER ALLOWANCES FOR BUILDING EXTERIORS

	LIGHTING ZONES			
	Zone 1	Zone 2	Zone 3	Zone 4
Building facades	No allowance	0.075 W/ft^2 of gross above-grade wall area	0.113 W/ft^2 of gross above-grade wall area	0.15 W/ft^2 of gross above-grade wall area
Automated teller machines (ATM) and night depositories	135 W per location plus 45 W per additional ATM per location			
Uncovered entrances and gate-house inspection stations at guarded facilities	0.50 W/ft^2 of area			
Uncovered loading areas for law enforcement, fire, ambulance and other emergency service vehicles	0.35 W/ft^2 of area			
Drive-up windows and doors	200 W per drive through			
Parking near 24-hour retail entrances.	400 W per main entry			

For SI: For SI: 1 watt per square foot = W/0.0929 m^2.
W = watts.

REVIEW DEADLINE: 1/1/2029

4.5.8 Miscellaneous Commercial/Industrial Lighting

DESCRIPTION

This measure is designed to calculate savings from energy efficient lighting upgrades that are not captured in other measures within the TRM. If a lighting project fits the measure description in other lighting measures, then those criteria, definitions, and calculations should be used.

Unlike other lighting measures this one applies only to RF applications (because there is no defined baseline for TOS or NC applications).

DEFINITION OF EFFICIENT EQUIPMENT

A lighting fixture that replaces an existing fixture to provide the same or greater lumen output at a lower kW consumption.

DEFINITION OF BASELINE EQUIPMENT

The definition of baseline equipment is the existing lighting fixture.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The lifetime of the efficient equipment fixture is the rated fixture life divided by hours of use. If unknown the default lifetime for interior fixtures, regardless of program type is 15 years.[1332]

For exterior fixtures, the lifetime is assumed to be 16 years for Dusk-to-Dawn (4303 hours) applications, or 25 years for Dusk-to-Business-Close Year Round (1609 hours) and Dusk-to-Business-Close Seasonal (<1000 hours).[1333]

DEEMED MEASURE COST

The actual cost of the efficient light fixture should be used.

LOADSHAPE

Loadshape C06 - Commercial Indoor Lighting
Loadshape C07 - Grocery/Conv. Store Indoor Lighting
Loadshape C08 - Hospital Indoor Lighting
Loadshape C09 - Office Indoor Lighting
Loadshape C10 - Restaurant Indoor Lighting
Loadshape C11 - Retail Indoor Lighting
Loadshape C12 - Warehouse Indoor Lighting
Loadshape C13 - K-12 School Indoor Lighting
Loadshape C14 - Indust. 1-shift (8/5) (e.g., comp. air, lights)
Loadshape C15 - Indust. 2-shift (16/5) (e.g., comp. air, lights)
Loadshape C16 - Indust. 3-shift (24/5) (e.g., comp. air, lights)
Loadshape C17 - Indust. 4-shift (24/7) (e.g., comp. air, lights)
Loadshape C18 - Industrial Indoor Lighting
Loadshape C19 - Industrial Outdoor Lighting
Loadshape C20 - Commercial Outdoor Lighting

[1332] 15 years is used based on assumption that most product using this measure will be LED.
[1333] Exterior fixture measure lives are based upon review of the typical rated life of the fixtures, divided by the hours of use assumption and applying a derating factor of 15% to account for potential impacts from external installation (as proposed in a Guidehouse EUL methodology recommendation for Street Lights).

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the location type. Values are provided for each building type in section 4.5.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * Hours * WHFe$$

Where:

$Watts_{base}$ = Input wattage of the existing system which depends on the baseline fixture configuration (number and type of lamp) and ballast factor (if applicable) and number of fixtures.

= Actual

$Watts_{EE}$ = New Input wattage of EE fixture which depends on new fixture configuration (number of lamps) and ballast factor (if applicable) (if applicable) and number of fixtures.

= Actual

Hours = Average hours of use per year as provided by the customer or selected from the Reference Table in Section 4.5, Fixture annual operating hours, by building type. If hours or building type are unknown, use the Miscellaneous value.

WHF_e = Waste heat factor for energy to account for cooling energy savings from efficient lighting is selected from the Reference Table in Section 4.5 for each building type. If building is un-cooled, the value is 1.0.

ISR = In Service Rate or the percentage of units rebated that get installed.

=100% if application form completed with sign off that equipment is not placed into storage.[1334] If sign off form not completed assume the following 3 year ISR assumptions:

Weighted Average 1st year In Service Rate (ISR)	2nd year Installations	3rd year Installations	Final Lifetime In Service Rate
93.4%[1335]	2.5%	2.1%	98.0%[1336]

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}[1337] = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * Hours * -IFkWh$$

Where:

[1334]Illinois evaluation of PY1 through PY3 has not found that fixtures or lamps placed into storage to be a significant enough issue to warrant including an "In-Service Rate" when commercial customers complete an application form.

[1335] Based on assumptions from 4.5.3 High Performance and Reduced Wattage T8 fixtures.

[1336] The 98% Lifetime ISR assumption is based upon review of two evaluations:
'Nexus Market Research, RLW Analytics and GDS Associates study; "New England Residential Lighting Markdown Impact Evaluation, January 20, 2009' and 'KEMA Inc, Feb 2010, Final Evaluation Report:, Upstream Lighting Program, Volume 1.' This implies that only 2% of bulbs purchased are never installed. The second and third year installations are based upon Ameren analysis of the Californian KEMA study showing that 54% of future installs occur in year 2 and 46% in year 3. The 2nd and 3rd year installations should be counted as part of those future program year savings.

[1337]Negative value because this is an increase in heating consumption due to the efficient lighting.

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

DEFERRED INSTALLS

As presented above, if a sign off form is not completed the characterization assumes that a percentage of bulbs purchased are not installed until Year 2 and Year 3 (see ISR assumption above). The Illinois Technical Advisory Committee has determined the following methodology for calculating the savings of these future installs.

Year 1 (Purchase Year) installs: Characterized using assumptions provided above or evaluated assumptions if available.

Year 2 and 3 installs: Characterized using delta watts assumption and hours of use from the Install Year, i.e., the actual deemed (or evaluated if available) assumptions active in Year 2 and 3 should be applied.

The NTG factor for the Purchase Year should be applied.

SUMMER COINCIDENT DEMAND SAVINGS

$$\Delta kW = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * WHFd * CF$$

Where:

WHFd = Waste Heat Factor for Demand to account for cooling savings from efficient lighting in cooled buildings is selected from the Reference Table in Section 4.5 for each building type. If the building is not cooled WHFd is 1.

CF = Summer Peak Coincidence Factor for measure is selected from the Reference able in Section 4.5 for each building type. If the building type is unknown, use the Miscellaneous value of 0.66.

Other factors as defined above.

FOSSIL FUEL SAVINGS

$$\Delta Therms^{1338} = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * Hours * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Integration Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficient lighting. This value is selected from the Reference Table in Section 6.5 for each building type.

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

If there are differences between the maintenance of the efficient and baseline lighting system then they should be evaluated on a project-by-project basis.

[1338]Negative value because this is an increase in heating consumption due to the efficient lighting.

4.5.9 Multi-Level Lighting Switch

DESCRIPTION

This measure relates to the installation of new multi-level lighting switches on an existing lighting system.

This measure can only relate to the adding of a new control in an existing building, since multi-level switching is required in the Commercial new construction building energy code (IECC 2012/2015/2018/2021).

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient system is assumed to be a lighting system controlled by multi-level lighting controls.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be an uncontrolled lighting system where all lights in a given area are on the same circuit or all circuits come on at the same time.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for all lighting controls is assumed to be 10 years.[1339]

DEEMED MEASURE COST

When available, the actual cost of the measure shall be used. When not available, the incremental capital cost for this measure is assumed to be $55.[1340]

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the location type. Values are provided for each building type in Section 4.5.

[1339] Consistent with 4.5.10 Lighting Control measure.
[1340] Consistent with Interior Wall Switch Occupancy Sensor from 4.5.10 Lighting Control measure.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = KW_{Controlled} * Hours * ESF * WHFe$$

Where:

$KW_{Controlled}$ = Total lighting load connected to the control in kilowatts.

= Actual

Hours = total operating hours of the controlled lighting circuit before the lighting controls are installed. This number should be collected from the customer. Average hours of use per year are provided in the Reference Table in Section 4.5, Fixture annual operating hours, for each building type if customer specific information is not collected. If unknown buidling type, use the Miscellaneous value.

ESF = Energy Savings factor (represents the percentage reduction to the KWcontrolled due to the use of multi-level switching).

= Dependent on building type:[1341]

Building Type	Energy Savings Factor (ESF)
Private Office	21.6%
Open Office	16.0%
Retail	14.8%
Classrooms	8.3%
Unknown, average	15%

WHF_e = Waste heat factor for energy to account for cooling energy savings from efficient lighting is provided in the Reference Table in Section 4.5 for each building type. If building is un-cooled, the value is 1.0.

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}[1342] = KW_{Controlled} * Hours * ESF * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = KW_{Controlled} * ESF * WHFd * ((CFbaseline * BaseAdj) - CF_{ML})$$

Where:

[1341] Based on results from "Lighting Controls Effectiveness Assessment: Final Report on Bi-Level Lighting Study" published by the California Public Utilities Commission (CPUC), prepared by ADM Associates.

[1342] Negative value because this is an increase in heating consumption due to the efficient lighting.

WHF_d = Waste Heat Factor for Demand to account for cooling savings from efficient lighting in cooled buildings is provided in the Reference Table in Section 4.5. If the building is un-cooled WHFd is 1.

CFbaseline = Baseline Summer Peak Coincidence Factor for the lighting system without lighting controls installed selected from the Reference Table in Section 4.5 for each building type. If the building type is unknown, use the Miscellaneous value of 0.66

BaseAdj = Assume 0.5 if existing lighting controls, 1.0 if no existing controls

CF_{ML} = Retrofit Summer Peak Coincidence Factor the lighting system with multi-level switch installed is 0.15 regardless of building type.[1343]

FOSSIL FUEL SAVINGS

$$\Delta\text{therms} = KW_{Controlled} * Hours * ESF * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Integration Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficient lighting and provided in the Reference Table in Section 4.5 by building type.

MEASURE CODE: CI-LTG-MLLC-V07-260101

REVIEW DEADLINE: 1/1/2030

[1343] Coincidence Factor Study Residential and Commercial Industrial Lighting Measures, RLW Analytics, Spring 2007. Note, the connected load used in the calculation of the CF for occupancy sensor lights includes the average ESF.

4.5.10 Lighting Controls

DESCRIPTION

This measure relates to the installation of new occupancy or daylighting sensors and controls on a new or existing lighting system. Lighting control types covered by this measure include wall, ceiling, fixture mounted or integrated controls in addition to Luminaire Level Lighting Controls (LLLCs) or Networked Lighting Controls (NLC) which have additional high-end trim and networking capabilities. Passive infrared, ultrasonic detectors and fixture-mounted sensors or sensors with a combination thereof are eligible. Lighting controls required by state energy codes are not eligible. This must be a new installation with additional control features and may not soley be a replacement of an existing lighting control with the same control features.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Lighting that is controlled by any of the control strategies characterized in this measure; occupancy, daylighting or dual (occupancy and daylighting) controls with or without high-end trim, and Luminaire-level lighting controls (LLLCs) / Networked Lighting Controls (NLC).

LLLCs or NLCs are defined according to DesignLights Consortium (DLC) Networked Lighting Controls definition, which requires systems to have fixture networking capabilities, individual addressability, occupancy sensing, daylight harvesting, high-end trim, flexible zoning, continuous dimming, scheduling and cybersecurity. The network ability allows building managers to group lights with specific zonal control and scheduling strategies, energy monitoring and high-end trim resulting in a higher savings capability. While DLC listing is not a requirement for any control type characterized in this measure, programs should consider eligibility requirements including requiring at least the capability for network controlled occupancy, daylight harvesting and high-end trim to ensure quality product is installed achieving forecasted savings consistent with the measure assumptions below.

A subset of occupancy sensors are those that are programmed as “vacancy” sensors. To qualify as a vacancy sensor, the control must be configured such that manual input is required to turn on the controlled lighting and the control automatically turns the lighting off. Additional savings are achieved compared to standard occupancy sensors because lighting does not automatically turn on and occupants may decide to not turn it on. Note that vacancy sensors are not a viable option for many applications where standard occupancy sensors should be used instead.

DEFINITION OF BASELINE EQUIPMENT

The baseline is assumed to be the existing lighting system and can include manual or no controls or an existing control strategy that is being improved. Note where an existing inefficient fixture is replaced with an efficient fixture with control, use the fixture measure to calculate savings from the wattage reduction first, then assume the efficient fixture without control as the baseline for the control measure.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for Luminaire-level lighting controls (LLLCs) / Networked Lighting Controls (NLC) is assumed to be 15 years, consistent with the average expected lifetime of the fixture. For all other lighting controls, measure life is assumed to be 10 years.[1344]

DEEMED MEASURE COST

When available, the actual cost of the measure shall be used. When not available, the following default values are provided:

[1344] Based on research conducted by Guidehouse, interviewing 46 contractors, reported in ‘ComEd Retrofit Add-On EUL Results Memo. January 27, 2020.

Lighting Control Type	Incremental Cost[1345]
Interior Wall Switch Occupancy Sensor	$55.00
Interior Fixture-Mounted Occupancy Sensor	$67.00
Interior Remote or Wall-Mounted Occupancy Sensor	$125.00
Interior Fixture-Mounted Daylight Sensor	$50.00
Interior Remote or Wall-Mounted Daylight Sensor	$65.00
Interior Integrated Occupancy for LED Interior Fixtures < 10,000 Lumens	$40.00
Interior Integrated Occupancy for LED Interior Fixtures >= 10,000 Lumens	$40.00
Interior Integrated Dual Occupancy & Daylight Sensor for LED Interior Fixtures < 10,000 Lumens	$50.00
Interior Integrated Dual Occupancy & Daylight Sensor for LED Interior Fixtures >= 10,000 Lumens	$50.00
Interior Fixture-Mounted Dual Occupancy & Daylight Sensor for LED Interior Fixtures < 10,000 Lumens	$ 100.00
Interior Fixture-Mounted Dual Occupancy & Daylight Sensor for LED Interior Fixtures >= 10,000 Lumens	$ 100.00
Luminaire-Level Lighting Controls	$56.00
Interior Networked Lighting Controls <10,000 sqft building	$0.86 per ft^2
Interior Networked Lighting Controls 10,000-100,000 sqft building	$0.59 per ft^2
Interior Networked Lighting Controls >100,000 sqft building	$0.40 per ft^2
High End Trim or Institutional Tuning	$0.06 per ft^2
Exterior Occupancy Sensor	$82.00
Exterior NLC	Use actual

[1345] Based on indicative product cost review as performed for Efficiency Vermont TRM. Cost assumption for Luminaire Level Lighting Controls is based on the average of 'clever' and 'clever-hybrid' LLLC incremental costs, including a per fixture contribution to the necessary gateway, servers and installation labor from Kisch et al, "2020 Luminaire Level Lighting Controls Incremental Cost Study", Energy Solutions on behalf of NEEA, January 2021. Cost assumptions for Interior Networked Lighting Controls is based on the average of "office", "warehouse", and "retail" by building size from Schwartz et al., "The Value Proposition for Cost-Effective, Demand Responsive-Enabling Nonresidential Lighting System Retrofits in California Buildings", Lawrence Berkeley National Laboratory and Energy Solutions prepared for California Energy Commission, April 2019.This includes both material and labor cost estimates.
Cost for High End Trim / Institutional Tuning is based on estimate provided by SlipStream based on field implementation.

Loadshape C19 - Industrial Outdoor Lighting

Loadshape C20 - Commercial Outdoor Lighting

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on building type and can be found in the Reference Table in Section 4.5.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = KW_{Controlled} * Hours * (ESF_{EE} - ESF_{Base}) * WHFe$$

Where:

$KW_{Controlled}$ = Total lighting load connected to the control in kilowatts. The total connected load per control should be collected from the customer or the default values presented below used. Note where an existing inefficient fixture is replaced with an efficient fixture with control, use the fixture measure to calculate savings from the wattage reduction first, then assume the efficient fixture without control as the baseline for the control measure.

Lighting Control Type[1346]	Wattage Unit	Default kW Controlled
Interior Wall Switch Occupancy Sensor	per control	0.084
Interior Fixture-Mounted Occupancy Sensor	per fixture	0.081
Interior Remote or Wall-Mounted Occupancy Sensor	per control	0.338
Interior Fixture-Mounted Daylight Sensor	per fixture	0.095
Interior Wall-Mounted Daylight Sensor	per control	0.239
Interior Integrated Occupancy for LED Interior Fixtures < 10,000 Lumens	per fixture	0.031
Interior Integrated Occupancy for LED Interior Fixtures >= 10,000 Lumens	per fixture	0.118
Interior Integrated Dual Occupancy & Daylight Sensor for LED Interior Fixtures < 10,000 Lumens	per control	0.031
Interior Integrated Dual Occupancy & Daylight Sensor for LED Interior Fixtures >= 10,000 Lumens	per control	0.118
Interior Fixture-Mounted Dual Occupancy & Daylight Sensor for LED Interior Fixtures < 10,000 Lumens	per control	0.031
Interior Fixture-Mounted Dual Occupancy & Daylight Sensor for LED Interior Fixtures >= 10,000 Lumens	per control	0.118
Interior Luminaire-Level Lighting Controls < 10,000 Lumens	per control	0.031
Interior Luminaire-Level Lighting Controls >= 10,000 Lumens	per control	0.118

[1346] Estimates of watts controlled are based on Efficiency Vermont data as provided in the 2018 TRM. Future evaluation should determine appropriate assumptions based on Illinois program data. Estimated kilowatts per sqft for interior networked lighting controls is based on the lighting power density (LPD) assumption in the Wisconsin Focus on Energy 2019 Technical Reference Manual and divided by 1000. To determine the total $KW_{Controlled}$ multiply by the controlled sqft. Either the total $KW_{Controlled}$ or the total sqft must be reported to estimate savings from interior networked lighting controls.

Lighting Control Type[1346]	Wattage Unit	Default kW Controlled
Interior Networked Lighting Controls	kilowatts controlled per sqft	0.00061
Refrigerated Case Occupancy Sensor – Freezer and Cooler	per control	0.090
Exterior Occupancy Sensor	per fixture	0.086
Exterior NLC	kilowatts controlled per sqft	Use actual

Hours = total operating hours of the controlled lighting circuit before the lighting controls are installed. This number should be collected from the customer if possible. If not possible, assume hours as prescribed below:

Control Type	General Building Type[1347]	Reference Table in Section 4.5 Mapped Building/Space Types	Hours
Networked Lighting Controls and Luminaire-Level Lighting Controls	Education	Childcare/Pre-School, College, Elementary School, High School	4,231
	Manufacturing	Manufacturing Facility	5,365
	Office	Office - High Rise - CAV no econ, Office - High Rise- CAV econ, Office- High Rise- VAV econ, Office- High Rise - FCU, Office- Low Rise, Office - Mid Rise	4,453
	Retail	Convenience Store, Drug Store, Grocery, Retail - Department Store, Retail - Strip Mall	6,936
	Warehouse	Warehouse	5,116
	All Other	All other building/space types in the Reference Table in Section 4.5	Use Fixture Annual Operating Hours in the Reference Table in Section 4.5
All other	All	All	Use Fixture Annual Operating Hours in the Reference Table in Section 4.5

ESF = Energy Savings Factor (represents the percentage reduction to the operating Hours from the non-controlled lighting system) from the new lighting controls installed. Where available and with building owner consent, custom savings from controls may be used via networked trending software. If unavailable or consent not provided, defaults are provided below which assume installation is appropriate to provide the savings described. For dual controls and fixtures with high-end trim this should be reviewed and verified via representative spot checks to ensure daylighting capabilities will provide savings and fixture tuning is being performed.[1348]

[1347] These are the general building types and the inferred baseline operating hours reported in DesignLights Consortium and NEEA, "Energy Savings from Networked Lighting Control (NLC) Systems with and without LLLC" Energy Solutions, September 2020. The inferred operating hours for "Assembly", "Healthcare", and "Restaurant" were excluded due to the reported small sample size (n=3, n-2, n=3 respectively). The mapping of the general building types to the building/space types listed in Section 4.5 Reference Table was completed by Guidehouse Inc.

[1348] It is recommended that evaluation is performed to assess the extent to which daylighting and high-end trim benefits are appropriately utilized in the field.

Lighting Control Type	Energy Savings Factor[1349]
Fixture Measurement of Control savings through Networked Trending (Interior or Exterior)	Custom
Interior Occupancy Sensor (Switch, Wall, Fixture or Remote Mounted or Integrated in Fixture)	24% 37% with High End Trim
Interior Occupancy Sensor configured as "Vacancy Sensor" (Switch, Wall, Fixture or Remote Mounted or Integrated in Fixture)	31% 44% with High End Trim
Interior Daylight Sensor (Wall, Fixture or Remote Mounted)	28% 41% with High End Trim
Interior Dual Occupancy & Daylight Sensor (Integrated of Fixture Mounted)	38% 51% with High End Trim[1350]
Interior Networked Luminaire-Level Lighting Controls	61%[1351]
Interior Networked Lighting Controls Only with No LLLCs	35%
Interior Networked Lighting Controls (unknown or mixed LLLCs)	49%
Refrigerated Case Occupancy Sensor – Freezer and Cooler	27%
Exterior Occupancy Sensor	41%
Exterior Networked Luminaire-Level Lighting Controls	61%[1352]
Exterior Networked Lighting Controls Only with No LLLCs	35%

[1349] Interior controls % savings based except where noted on LBNL, Williams et al, "Lighting Controls in Commercial Buildings", 2012, p172. ESF for Vacancy Sensors is based on Papamichael, Konstantions, Bi-Level Switching in Office Spaces, California Lighting Technology Center, February 1,2010. See Figure 8 on page 10 for relevant study results. The study shows a 30% extra savings above a typical occupancy sensor; 24% * 1.3 = 31%.

ESF for Luminaire Level Lighting Controls, Networked Lighting Controls and the 13% High End Trim adder are based upon the weighted average of results from:

Pacific Northwest National Laboratory, "Evaluation of Advanced Lighting Control Systems in a Working Office Environment", November 2018.

Schuetter et al., "Cree SmartCast Lighting Retrofit Demonstration: LED Fixtures and Controls for Advanced Holistic Lighting Solutions", September 2020 (expected).

DesignLights Consortium and NEEA, "Energy Savings from Networked Lighting Control (NLC) Systems with and without LLLC" Energy Solutions, September 2020.. LLLC ESF used in weighted average is the average of all 98 sites with NLCs w/LLLC. NLC ESF is the average of all 194 buildings. High-end trim adder used for other lighting control types is based on the results for the 96 sites w NLCs w/o LLLC and using the "Other Control Strategies" savings where the baseline had influences from high-end trim removed.

Refrigerated Case occupancy sensors ESF is based on percentage of operating hours spent in low-power operation during vacant periods, found in SDG&E workpaper: WPSDGENRLG0027.

Exterior sensors are based upon data from "Application Assessment of Bi-Level LED Parking Lot Lighting" p6.

[1350] The ESF_{EE} for interior dual occupancy & daylight sensor with high-end trim is estimated to be higher than the interior networked lighting control ESF_{EE} since this measure requires that the sensors be integrated or fixture mounted which has been documented to lead to higher savings than zone or wall sensors. The NLC measure is not specific to fixture, zone, or wall sensors.

[1351] The ESF_{EE} for LLLC is not separated out based on the inclusion of high-end trim since the DesignLights Consortium Technical Requirements Version NLC5 (1/25/21) requires that high-end trim is included for all interior networked lighting controls including LLLC.

[1352] In the absence of evaluation results specifically for exterior networked lighting controls with or without LLLCs, the same ESFs are assumed as the equivalent interior lighting controls. This is consistent with the value provided in 'Energy Savings Forecast of SolidState Lighting in General Illumination Application, Table F.4 - Building Exterior, DOE, 2019' which indicates a savings of 48% for Exterior NLCs (unknown LLC).

Lighting Control Type	Energy Savings Factor[1349]
Exterior Networked Lighting Controls (unknown or mixed LLLCs)	49%
No Lighting Control	0%

ESF_{Base} = Energy Savings Factor of the lighting controls that existed before the new lighting controls were installed. If prior existence of lighting controls is unknown, assume 0.

WHF_e = Waste heat factor for energy to account for cooling energy savings from efficient lighting is provided in the Reference Table in Section 4.5 for each building type. If building is un-cooled, the value is 1.0.

For example, a 1,000 sqft. low-rise office building, with cooling, installing 10 networked, interior fixture-mounted occupancy sensors would save:

$\Delta kWh = KW_{controlled} * HOURS * (ESF_{EE} – ESF_{Base}) * WHF_e$

$= 0.81 * 4{,}453 * (24\% - 0\%) * 1.10$

$= 952.2$ kWh

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}[1353] = KW_{Controlled} * Hours * (ESF_{EE} - ESF_{Base}) * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

For example, a 1,000 sqft. low-rise office building, with electrical reistance heating, installing 10 networked, interior fixture-mounted occupancy sensors would have the following heating penalty:

$\Delta kWh_{heatpenalty} = KW_{controlled} * HOURS * (ESF_{ee} – ESF_{Base}) * -IfkWh$

$= 0.81 * 4{,}453 * (24\% - 0\%) * -0.231$

$= -200$ kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = KW_{Controlled} * WHFd * ((CF_{baseline} * BaseAdj) - CF_{LC})$$

Where:

WHF_d = Waste Heat Factor for Demand to account for cooling savings from efficient lighting in cooled buildings is provided in the Reference Table in Section 4.5. If the building is un-cooled WHFd is 1.

[1353] Negative value because this is an increase in heating consumption due to the efficient lighting.

CFbaseline = Baseline Summer Peak Coincidence Factor for the lighting system without lighting controls installed selected from the Reference Table in Section 4.5 for each building type. If the building type is unknown, use the Miscellaneous value of 0.66

BaseAdj = Assume 0.5 if existing lighting controls, 1.0 if no existing controls

CF_{LC} = Retrofit Summer Peak Coincidence Factor the lighting system with lighting controls installed is 0.15 regardless of building type.[1354]

For controls on exterior fixtures ΔkW = 0

For example, a 1,000 sqft. low-rise office building, with no existing lighting controls, installing 10 networked, interior fixture-mounted occupancy sensors would save:

ΔkW = $KW_{controlled}$ * WHF_d * ((Cfbaseline * BaseAdj) – CF_{LC})

= 0.81 * 1.26 * ((0.52 * 1) – 0.15)

= 0.38 kW

FOSSIL FUEL SAVINGS

$$\Delta\text{therms} = KW_{Controlled} * Hours * (ESF_{EE} - ESF_{Base}) * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Integration Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficient lighting and provided in the Reference Table in Section 4.5 by buidling type.

For example, a 1,000 sqft. low-rise office building installing 10 networked, interior fixture-mounted occupancy sensors would save:

ΔTherms = $KW_{Controlled}$ * HOURS * (ESF_{EE} – ESF_{Base}) * - IFTherms

= 0.81 * 4,453 * (24% - 0%) * -0.01

= -8.7 therms

4.5.11 Solar Light Tubes

DESCRIPTION

A tubular skylight which is 10" to 21" in diameter with a prismatic or translucent lens is installed on the roof of a commercial facility. The lens reflects light captured from the roof opening through a highly specular reflective tube down to the mounted fixture height. When in use, a light tube fixture resembles a metal halide fixture. Uses include grocery, school, retail and other single story commercial buildings.

In order that the savings characterized below apply, the electric illumination in the space must be automatically controlled to turn off or down when the tube is providing enough light.

This measure was developed to be applicable to the following program types: TOS, NC, RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is assumed to be a tubular skylight that concentrates and directs light from the roof to an area inside the facility.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment for this measure is a fixture with comparable luminosity. The specifications for the baseline lamp depend on the size of the Light Tube being installed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated useful life for a light tube commercial skylight is 10 years.[1355]

DEEMED MEASURE COST

If available, the actual incremental cost should be used. For analysis purposes, assume an incremental cost for a light tube commercial skylight is $750.[1356]

LOADSHAPE

Loadshape C14 - Indust. 1-shift (8/5) (e.g., comp. air, lights)[1357]

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on location.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = kW_f * HOURS * WHFe$$

Where:

kW_f = Connected load of the fixture the solar tube replaces

[1355] Equal to the manufacturers standard warranty.
[1356] Based on review of solar lighting installers websites (e.g., elitesolarsystems.com).
[1357] The savings from solar light tubes are only realized during the sunlight hours. It is therefore appropriate to apply the single shift (8/5) loadshape to this measure.

Size of Tube	Average Lumen output for Chicago Illinois (minimum)[1358]	Equivalent fixture	kW
21"	9,775 (4,179)	50% 3 x 2 32W lamp CFL (207W, 9915 lumens) 50% 4 lamp F32 w/Elec 4' T8 (114W, 8895 lumens)	0.161
14"	4,392 (1,887)	50% 2 42W lamp CFL (94W, 4406 lumens) 50% 2 lamp F32 w/Elec 4' T8 (59W, 4448 lumens)	0.077
10"	2,157 (911)	50% 1 42W lamp CFL (46W, 2203 lumens) 50% 1 lamp F32 w/Elec 4' T8 (32W, 2224 lumens)	0.039
		AVERAGE	0.092

HOURS = Equivalent full load hours

= 2400 [1359]

WHF_e = Waste heat factor for energy to account for cooling energy savings from efficient lighting is selected from the Reference Table in Section 4.5 for each building type. If building is un-cooled, the value is 1.0.

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}{}^{1360} = kW_f * HOURS * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = kW_f * WHFd * ((CFbaseline * BaseAdj) - CFSL)$$

Where:

WHFd = Waste Heat Factor for Demand to account for cooling savings from efficient lighting in cooled buildings is selected from the Reference Table in Section 4.5 for each building type. If the building is not cooled WHFd is 1.

CF = Summer Peak Coincidence Factor for measure is selected from the Reference Table in Section 4.5 for each building type. If the building type is unknown, use the Miscellaneous value of 0.66.

CFbaseline = Baseline Summer Peak Coincidence Factor for the lighting system selected from the Reference Table in Section 4.5 for each building type. If the building type is unknown, use the Miscellaneous value of 0.66

BaseAdj = Assume 0.5 if existing lighting controls, 1.0 if no existing controls

[1358] Solatube Test Report (2005). http://www.mainegreenbuilding.com/files/file/solatube/stb_lumens_datasheet.pdf.
[1359] Ibid. The lumen values presented in the kW table represent the average of the lightest 2400 hours.
[1360] Negative value because this is an increase in heating consumption due to the efficient lighting.

CF_{SL} = Retrofit Summer Peak Coincidence Factor the lighting system with solar light tube installed is 0.15 regardless of building type.[1361]

FOSSIL FUEL SAVINGS

$$\Delta\text{Therms}^{1362} = kW_f * HOURS * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Integration Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficient lighting. Please select from the Reference Table in Section 4.5 for each building type.

4.5.12 T5 Fixtures and Lamps – Retired 12/31/2025, Removed in v14

4.5.13 Occupancy Controlled Bi-Level Lighting Fixtures

DESCRIPTION

This measure relates to replacing existing uncontrolled continuous lighting fixtures with new bi-level lighting fixtures. This measure can only relate to replacement in an existing building, since multi-level switching is required in the Commercial new construction building energy code (IECC 2012/2015/2018/2021). This measure is limited to 24/7 operation.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient system is assumed to be an occupancy controlled lighting fixture operating 24/7, that reduces light level during unoccupied periods.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be an uncontrolled lighting system on continuously, e.g. in stairwells and corridors for health and safety reasons.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for all lighting controls is assumed to be 10 years.[1363]

DEEMED MEASURE COST

When available, the actual cost of the measure shall be used. When not available, the assumed measure cost is $274.[1364]

[1363] Consistent with Lighting Controls measure.
[1364] Consistent with the Multi-level Fixture measure with reference to Goldberg et al, State of Wisconsin Public Service Commission of Wisconsin, Focus on Energy Evaluation, Business Programs: Incremental Cost Study, KEMA, October 28, 2009. Also consistent with field experience of about $250 per fixture and $25 install labor.

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the location type. Values are provided for each building type in the reference section below.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (KW_{Baseline} - (KW_{Controlled} * (1 - ESF))) * Hours * WHF_e$$

Where:

$KW_{Baseline}$ = Total baseline lighting load of the existing/baseline fixture

= Actual

Note that if the existing fixture is only being retrofit with bi-level occupancy controls and not being replaced $KW_{Baseline}$ will equal $KW_{Controlled}$.

$KW_{Controlled}$ = Total contolled lighting load at full light output of the new bi-level fixture

= Actual

Hours = Number of hours lighting is on. This measure is limited to 24/7 operation.

= 8,766

ESF = Energy Savings factor (represents the percentage reduction to the $KW_{Controlled}$ due to the occupancy control).

= % Standby Mode * (1 - % Full Light at Standby Mode)

% Standby Mode = Represents the percentage of the time the fixture is operating in standby (i.e. low-wattage) mode.

% Full Light at Standby Mode = Represents the assumed wattage consumption during standby mode relative to the full wattage consumption. Can be achieved either through dimming or a stepped control strategy.

= Dependent on application. If participant provided or metered data is available for both or either of these inputs a custom savings factor should be calculated. If not defaults are provided below:

Application	% Standby Mode	% Full Light at Standby Mode	Energy Savings Factor (ESF)
Stairwells	78.5%[1365]	50%	39.3%
		33%	52.6%
		10%	70.7%
		5%	74.6%
Corridors	50.0%[1366]	50%	25.0%
		33%	33.5%
		10%	45.0%

[1365] Average found from the four buildings in the State of California Energy Commission Lighting Research Program Bi-Level Stairwell Fixture Performance Final Report, October 2005.

[1366] Value determined from the Pacific Gas and Electric Company: Bi-Level Lighting Control Credits study for Interior Corridors of Hotels, Motels and High Rise Residential, June 2002.

Application	% Standby Mode	% Full Light at Standby Mode	Energy Savings Factor (ESF)
		5%	47.5%
Other 24/7 Space Type	50.0%[1367]	50%	25.0%
		33%	33.5%
		10%	45.0%
		5%	47.5%

WHF_e = Waste heat factor for energy to account for cooling energy savings from efficient lighting is provided in the Reference Table in Section 4.5 for each building type. If building is un-cooled, the value is 1.0.

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}[1368] = (KW_{Baseline} - (KW_{Controlled} * (1 - ESF))) * Hours * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (KW_{Baseline} - (KW_{Controlled} * (1 - ESF))) * WHF_d * (CF_{baseline} - CF_{os})$$

Where:

WHF_d = Waste Heat Factor for Demand to account for cooling savings from efficient lighting in cooled buildings is provided in the Reference Table in Section 4.5. If the building is un-cooled WHFd is 1.

$CF_{baseline}$ = Baseline Summer Peak Coincidence Factor for the lighting system without Occupancy Sensors installed.

= 1.0 (due to 24/7 operation)

CF_{os} = Retrofit Summer Peak Coincidence Factor the lighting system with Occupancy Sensors installed.

= 0.15 regardless of building type.[1369]

NATURAL GAS HEATING PENALTY

If natural gas heating:

$$\Delta therms = (KW_{Baseline} - (KW_{Controlled} * (1 - ESF))) * Hours * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Integration Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficient lighting and provided in the Reference Table in Section 4.5 by buidling type.

[1367] Conservative estimate.

[1368] Negative value because this is an increase in heating consumption due to the efficient lighting.

4.5.14 Commercial ENERGY STAR Specialty Compact Fluorescent Lamp (CFL) – Retired 12/31/2018, Removed in v8

4.5.15 LED Open Sign

DESCRIPTION

LED open signs must replace an existing neon open sign. LED drivers can be either electronic switching or linear magnetic, with the electronic switching supplies being the most efficient. The on/off power switch may be found on either the power line or load side of the driver, with the line side location providing significantly lower standby losses when the sign is turned off and is not operating. All new open signs must meet UL-84 (UL-844) requirements.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient product is an LED type illuminated open sign.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a neon type illuminated open sign.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated useful life is 15 years.[1370]

DEEMED MEASURE COST

The actual measure installation cost should be used (including material and labor).

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the location type. Values are provided for each building type in the reference section in Section 4.5.

[1370] 15 years from GDS Measure Life Report, June 2007.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

The following equation was used to determine the energy savings from installing LED open signs:

$$\Delta kWh = \frac{(WattsBase - WattsEE)}{1{,}000} * Hours * WHFe$$

Where:

$Watts_{base}$ = Wattage of neon sign with magnetic high voltage transformer

= Actual; if unknown use 46.0W[1371]

$Watts_{ee}$ = Wattage of LED sign with low voltage transformer

= Actual; if unknown use 14.9W[1372]

Hours = Annual hours of operation, assumed to be consistent with operating hours. Values are provided in the Reference Table in Section 4.5.

WHFe = Waste heat factor for energy to account for cooling energy savings from efficient lighting are provided below for each building type in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}{}^{1373} = \frac{(WattsBase - WattsEE)}{1{,}000} * Hours * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

DEMAND SAVINGS

$$\Delta kW = \frac{(WattsBase - WattsEE)}{1{,}000} * WHFd * CF$$

Where:

WHFd = Waste Heat Factor for Demand to account for cooling savings from efficient lighting in cooled buildings is provided in Referecne Table in Section 4.5. If unknown, use the Miscellaneous value.

CF = Summer Peak Coincidence Factor for measure is provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

Other variables as provided above.

[1371] Measured average demand data. Southern California Edison, "Replace Neon Open Sign with LED Open Sign", Workpaper SCE13LG070, Revision 2, October 2015. Pg. 10.

[1372] Ibid.

[1373] Negative value because this is an increase in heating consumption due to the efficient lighting.

Based on defaults provided above, the deemed energy savings are provided below:

Electric Energy and Coincident Peak Demand Savings

Building Types[1374]	Energy Savings (kWh)	$\Delta kWh_{heatpenalty}$ (if electric resistance heat)	$\Delta kWh_{heatpenalty}$ (if electric heat pump heat)	Coincident Demand Savings (kW)
Convenience Store	158	-120	-52	0.0298
Grocery	179	-39	-17	0.0311
Healthcare Clinic	138	-56	-24	0.0217
Hotel/Motel - Common	208	-78	-34	0.0333
Movie Theater	121	-73	-32	0.0227
Restaurant	187	-36	-16	0.0342
Retail - Department Store	135	-44	-19	0.0310
Miscellaneous	113	-37	-16	0.0271

FOSSIL FUEL SAVINGS

Heating Penalty if fossil fuel heated building (or if heating fuel is unknown):

$$\Delta Therms^{1375} = \frac{(WattsBase - WattsEE)}{1{,}000} * Hours * -IFTherms$$

Where:

IFTherms = Lighting-HVAC Interation Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

Other factors as defined above

Based on defaults provided above, the deemed penalty is provided below:

Building Type	$\Delta Therms_{heatpenalty}$ (if gas heat)
Convenience Store	-5.1
Grocery	-1.7
Healthcare Clinic	-2.4
Hotel/Motel - Common	-3.2
Movie Theater	-3.2
Restaurant	-1.6
Retail - Department Store	-1.9
Miscellaneous	-1.6

[1374] Savings can be calculated for additional building types using the default values provided in the Reference Table in Section 4.5.

[1375] Negative value because this is an increase in heating consumption due to the efficient lighting.

MEASURE CODE: CI-LTG-OPEN-V03-260101

REVIEW DEADLINE: 1/1/2029

4.5.16 LED Streetlighting

DESCRIPTION

Existing streetlights are retrofitted to be illuminated with light emitting diodes (LED) instead of less efficient lamps. Incentive applies for the replacement or retrofit of existing streetlights with new LED lamps.

This measure was developed to be applicable to the following program types: EREP, TOS*.
If applied to other program types, the measure savings should be verified.

* It is recommended to consider likely high freeridership for time of sale applications of this measure.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is the installed LED streetlight.

DEFINITION OF BASELINE EQUIPMENT

For TOS, baseline is assumed to be High Pressure Sodium lamp.

For early replacement, the baseline equipment is the existing streetlight for its' remaining useful life, and a new baseline High Pressure Sodium lamp for the remainder of the measure life. Where the existing fixture is Mercury Vapor (MV), the following table provides the deemed alignment of Mercury Vapor (MV) fixtures to High Pressure Sodium (HPS) for calculation of the midlife baseline adjustment.[1376]

MV Lamp Watts	MV System Watts	HPS Lamp Watts	HPS System Watts
100	125	50	66
175	205	100	138
250	290	100	138
400	455/469	250	295
1000	1075	400	465

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed effective useful life (EUL) of a new LED streetlight is 20 years for standard operation or 10 years for 8766 hour lighting.[1377]

For early replacement, it is assumed the existing unit has a remaining useful life (RUL) of 3 years for standard operation and 1.5 year for 8760 operation.[1378]

DEEMED MEASURE COST

The actual measure installation cost should be used (including material and labor). The assumed deferred cost (after 3 years for standard operation and 1.5 year for 8760 operation) of replacing the existing lamp with a new High

[1376] Midlife adjustment data is based on analysis by Guidehouse and is based on two years of AIC and ComEd program data, including 13,270 MV lamps and 96,780 HPS lamps. Both types of retrofits are mapped to the installed LED wattage, the resulting LED correlations are then used as a common frame of reference to align MV fixtures to the closest HPS equivalent. Results are further validated through the lumen equivalence method which confirms the alignments match the next closest lamp wattage, even if some HPS fixtures equate to higher lumen output whereas others provide lower output.

[1377] Based on research conducted by Guidehouse and reported in "ComEd LED St Lighting EUL Results Memo," January 27, 2020, Guidehouse reviewed a cross-section of products covered in 2019 energy conservation programs; these fixtures include the most commonly selected manufacturers and output spanning from 4,000 to 25,000 lumens. This review found that manufactures for the majority of LED streetlights installed through programs in IL have recently doubled the expected rated life to 100,000 hours.

[1378] Assuming an existing mercury vapor ballast with a typical rated life of 40,000. Assuming 1/3 remaining useful life and standard operation this equates to 40,000/3/4303 = 3 year remaining life, and 40,000/3/8760 = 1.5 year remaining life for 8760 operation.

Pressure Sodium lamp is assumed to be $44.[1379] This cost should be discounted to present value using the nominal discount rate.

LOADSHAPE

Loadshape C20 - Commercial Outdoor Lighting

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 0 for standard usage or 1.0 for 8766 hour lighting.[1380]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

For remaining useful life (1st 3 years for standard operation and 1.5 year for 8760 operation) of existing equipment:

(1) $\Delta kWh = (W_{exist} - W_{eff}) * HOURS / 1000$

For remaining life of measure (next 17 years for standard operation and 8.5 years for 8760 operation) or time of sale:

(2) $\Delta kWh = (W_{base} - W_{eff}) * HOURS / 1000$

Where:

W_{exist} =the connected load of the existing equipment

= actual existing equipment wattage

W_{base} =the connected load of the baseline equipment

= assume appropriate High Pressure Sodium lamp wattage for application, see mapping table in 'Definition of Baseline Equipment section above'

W_{eff} =the connected load of the efficient equipment

= actual efficient equipment wattage

EFLH = annual operating hours of the lamp

= 4,303 hours for standard operation[1381]

= 8,766 hours for always on lighting

1000 = conversion factor (W/kW)

Mid Life Baseline Adjustment

[1379] High Pressure Sodium replacement cost (lamp and labor) was provided by ComEd based on their composite maintenance rate.

[1380] Assuming standard operation of streetlight occurs outside the summer peak period of 1-5 PM. Coincidence Factor is assumed to equal 0.

[1381] Based on Navigant verified value using 2014 Astronomical Applications Department, U.S. Naval Observatory data for ComEd's service territory. See Navigant Memorandum 'RE: LED Street Lighting Program Hours of Use for the ComEd and DCEO Programs. June 21, 2017'.

To calculate the mid life adjustment, divide the savings for remaining life of measure (1), by the first year savings (2) as provided above.

For example, an existing streetlight that uses a single 175 watt mercury vapor lamp is replaced by a 42W LED fixture. Accounting for ballast factor, the system load for the existing fixture is 205 watts. The HPS equivalent for the midlife adjustment is a 100 W lamp with total system load of 138 W. For a fixture with standard operating profile, the first year and lifetime savings for this installation are found as follows:

ΔkWh (first three years) = ((205 - 42) * 4,303) / 1000

= 701.4 kWh / year

ΔkWh (remaining seventeen years) = ((138 - 42) * 4,303) / 1000

= 413.2 kWh / year

Therefore, a midlife adjustment of 58.9% (413.2/701.4) would be applied after 3 years.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (W_{base} - W_{eff} Wbase \;\; Wbase - Weff \;) / 1000 * CF$$

Where:

CF = Summer Peak Coincidence Factor for measure

= 0 for Standard operation

= 1 for 8766 lighting

FOSSIL FUEL SAVINGS

N/A

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

For EREP: to calculate an O&M adjustment, in addition to the deferred HPS replacement after 3 years, assume one additional HPS replacement lamp costing $44 in year nine and year fifteen for standard operation or every 2.7 years for 8,766 hour lighting.[1382]

For TOS: Assume one additional HPS replacement costing $44 every 6 years for standard operation or every 2.7 years for 8,766 hour lighting.

MEASURE CODE: CI-LTG-STRT-V04-250101

REVIEW DEADLINE: 1/1/2030

[1382] Assumes a rated life of the High Pressure Sodium lamp of 24,000 hours. High Pressure Sodium replacement cost (lamp and labor) was provided by ComEd based on their composite maintenance rate.

4.5.17 Exterior Photocell Repair

DESCRIPTION

This measure characterizes the repair of a photocell on an existing exterior light. A photocell is designed to switch exterior lights off during daylight hours, but if broken the fixtures may remain on 8760 hours.

This measure was developed to be applicable to the following program types: RF.
If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is an exterior light with a repaired or replaced photocell. The specifications and location of exterior lighting fixtures must be verified.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is an exterior light with a broken photocell.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed measure life is 2 years.[1383]

DEEMED MEASURE COST

The deemed measure cost is $65.52 per lighting sensor.[1384]

LOADSHAPE

Loadshape C19 - Industrial Outdoor Lighting
Loadshape C20 - Commercial Outdoor Lighting

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 1.0. The savings for this measure will be throughout the daytime hours.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{Watts_{fixture}}{1000} * (HOU_{PRE} - HOU_{POST})$$

Where:

$Watts_{fixture}$ = Input wattage of exterior lighting fixture(s) controlled by photocell

HOU_{PRE} = Fixture Annual Operating Hours before Photocell repair/replacement

= 8,766 hours[1385]

HOU_{POST} = Fixture Annual Operating Hours with Photocell repaired / replaced

[1383] Estimated remaining life of an exterior lamp running 8760 hours.
[1384] Wisconsin Focus on Energy TRM 2017 based on historical project data cost of 643 units over 31 projects from 2014 to 2018.
[1385] Exterior lighting with broken photocells are typically identified by visual inspection during the daytime and it is assumed that exterior lighting that is found to be on during daylight hours is on during *all* day and night hours.

= 4,303 hours[1386]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh}{(HOU_{PRE} - HOU_{POST})} * CF$$

Where:

CF = Summer Peak Coincidence Factor for measure

= 1 [1387]

FOSSIL FUEL SAVINGS

MEASURE CODE: CI-LTG-PHRP-V02-260101

REVIEW DEADLINE: 1/1/2030

[1386] Assumption for Dusk to Dawn as provided in Section 4.5.

[1387] The savings for this measure will be throughout the daytime hours when the repaired photocell turns lighting off.

4.5.18 Ultra-Efficient LED Lighting

DESCRIPTION

This characterization provides savings assumptions for variety of ultra-efficient LED screw-based lamps including Omnidirectional (e.g., A-Type lamps), Decorative (e.g., Globes and Torpedoes) and Directional (PAR Lamps, Reflectors, MR16).

If the implementation strategy does not allow for the installation location to be known, for Residential targeted programs (e.g., an upstream retail program), a deemed split of 97% Residential and 3% Commercial assumptions should be used,[1388] and for Commercial targeted programs a deemed split of 97% Commercial and 3% Residential for non-linear LED Bulbs and 100% Commercial and 0% Residential for LED Fixtures and TLEDs should be used.[1389]

This measure was developed to be applicable to the following program types: TOS, NC, EREP, DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, new lamps must exceed efficiency specifications defined in the Baseline Efficacy tables below. Consult the tables to find the *minimum efficacy* that can be considered ultra-efficient for each bulb type.

Actual lamp wattages of the efficient equipment should be used to determine savings.

DEFINITION OF BASELINE EQUIPMENT

For TOS, NC or Kit programs, the baseline equipment is a standard LED bulb. See Baseline Efficacy tables below for specific baseline efficacies by lamp type and lumen output.

For Direct Install programs where it can be shown that the LED bulb is replacing working inefficient lighting, the existing inefficient lighting is baseline for the assumed remaining life of the existing lamp, and a standard LED bulb for the remainder of the measure life. A mid-life adjustment is therefore applied after 2 years, see Mid-Life Adjustment section below.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The lifetime for screw-based lamps is calculated as the rated lifetime of the product (actual if available, otherwise assume 20,000 hours for Omnidirectional, 17,000 hours for decorative and 25,000 for directional lamps based on average rated life of lamps on the ENERGY STAR Qualified Products list (accessed 6/16/2020)) divided by the reported operating hours, capped at 10 years.[1390]
For direct install programs, a mid-life adjustment is applied after 2 years.

DEEMED MEASURE COST

The actual ultra-efficient LED lamp cost should be used. For incremental cost, assume a baseline cost according to the following table[1391]:

[1388] RES v C&I split is based on a weighted (by sales volume) average of ComEd PY8, PY9 and CY2018 and Ameren PY8 in store intercept survey results. See 'RESvCI Split_2019.xlsx.

[1389] Based on ComEd's Instant Discounts program CY2018, CY2019 and CY2020 (Rounds 1 and 2) Purchaser Survey analysis. See ComEd Instant Discounts Enduser Survey TRM Updates.xlsx. For Residential installations, hours of use assumptions from '5.5.6 LED Downlights' should be used for LED fixtures and '5.5.8 LED Screw Based Omnidirectional Bulbs' should be used for LED bulbs.

[1391] Baseline and LED lamp costs are based on field data collected by CLEAResult and provided by ComEd. See ComEd Pricing Projections 06302016.xlsx for analysis. Given LED prices are expected to continue declining assumed costs should be reassessed on an annual basis and replaced with IL specific LED program information when available.

Bulb Type	Standard LED Baseline Cost
Omnidirectional	$2.70
Directional	$5.18
Decorative and Globe	$3.40

For Direct Install, assume the full ultra-efficient LED install cost, and a deferred baseline replacement cost (after 2 years) as provided above. This cost should be discounted to present value using the nominal societal discount rate.

LOADSHAPE

Loadshape C06 - Commercial Indoor Lighting
Loadshape C07 - Grocery/Conv. Store Indoor Lighting
Loadshape C08 - Hospital Indoor Lighting
Loadshape C09 - Office Indoor Lighting
Loadshape C10 - Restaurant Indoor Lighting

Loadshape C14 - Indust. 1-shift (8/5) (e.g., comp. air, lights)
Loadshape C15 - Indust. 2-shift (16/5) (e.g., comp. air, lights)
Loadshape C16 - Indust. 3-shift (24/5) (e.g., comp. air, lights)
Loadshape C17 - Indust. 4-shift (24/7) (e.g., comp. air, lights)
Loadshape C18 - Industrial Indoor Lighting
Loadshape C19 - Industrial Outdoor Lighting
Loadshape C20 - Commercial Outdoor Lighting
Loadshape C60 – Non-Residential Agriculture Lighting – 6 Hours
Loadshape C61 – Non-Residential Agriculture Lighting – 8 Hours
Loadshape C62 – Non-Residential Agriculture Lighting – 12 Hours
Loadshape C63 – Non-Residential Dairy Long Day Lighting – 17 Hours
Loadshape C64 – Non-Residential Agriculture Lighting – 24 Hours

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the location type. Values are provided for each building type in the reference section below.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * Hours * WHFe$$

Where:

$Watts_{EE}$ = Actual wattage of LED purchased / installed must be used.

$Watts_{base}$ = $LumensEE / Efficacy_{Base}$

LumensEE = Lumens of ultra-efficient lamp

= Actual

$Efficacy_{Base}$ = Efficacy (Lumens/Watt) or standard efficiency LED baseline bulb.

= See table below[1392]:

Lamp Type	Minimum Lumens	Maximum Lumens	$Efficacy_{Base}$ (Lumens/Watt)
Omnidirectional	120	3299	93.6
Decorative	310	2700	100.6
Directional	310	3299	81.6
Additional EISA Non-Exempt Bulb Types	310	1999	91.1

Hours = Average hours of use per year are provided in the Reference Table in Section 4.5 for each building type. If unknown, use the Miscellaneous value.

WHFe = Waste heat factor for energy to account for cooling energy savings from efficient lighting are provided below for each building type in the Referecne Table in Section 4.5. If unknown, use the Miscellaneous value.

ISR = In Service Rate -the percentage of units rebated that actually get installed.

=100% if application form completed with sign off that equipment is not placed into storage.[1393] If sign off form not completed, assume the following ISR assumptions, if program survey data is not available:

Type	Lifetime In Service Rate (ISR)[1394]
LED Bulbs	97.6%[1395]
Efficiency Kits	92.4%[1396]

[1392] Average lumens per watt for each lamp type as provided in standard LED measures, based on Guidehouse file "LED Lamp Updates 2021-06-09".

[1393] Illinois evaluation of PY1 through PY3 has not found that fixtures or lamps placed into storage to be a significant enough issue to warrant including an "In-Service Rate" when commercial customers complete an application form.

[1394] In Service Rates now represent the lifetime In Service Rates with the second and third year installations discounted by the Real Discount Rate of 0.46%. Lifetime ISR assumptions for efficiency kits are based upon Residenital direct mailed kits. For all other programs Tthe 98% Lifetime ISR assumption is based upon the standard CFL measure in the absence of any better reference. This value is based upon review of two evaluations:
'Nexus Market Research, RLW Analytics and GDS Associates study; "New England Residential Lighting Markdown Impact Evaluation, January 20, 2009' and 'KEMA Inc, Feb 2010, Final Evaluation Report:, Upstream Lighting Program, Volume 1.' This implies that only 2% of bulbs purchased are never installed. The second and third year installations are based upon Ameren analysis of the Californian KEMA study showing that 54% of future installs occur in year 2 and 46% in year 3.

[1395] Based on ComEd's Instant Discounts program CY2019 and CY2020 (Rounds 1 and 2) Purchaser Survey analysis. See ComEd Instant Discounts Enduser Survey TRM Updates.xlsx

[1396] First year ISR is average ISR from CY2018, CY2019 and CY2020 ComEd Small Business Kit participant installation surveys. Please see file "SB Kits Survey Analysis TRMv10 Support.xlsx"

HEATING PENALTY

If electrically heated building:

$$\Delta kWh_{heatpenalty}{}^{1397} = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * Hours * -IFkWh$$

Where:

IFkWh = Lighting-HVAC Interation Factor for electric heating impacts; this factor represents the increased electric space heating requirements due to the reduction of waste heat rejected by the efficent lighting. Values are provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * WHFd * CF$$

Where:

WHFd = Waste Heat Factor for Demand to account for cooling savings from efficient lighting in cooled buildings is provided in Referecne Table in Section 4.5. If unknown, use the Miscellaneous value.

CF = Summer Peak Coincidence Factor for measure is provided in the Reference Table in Section 4.5. If unknown, use the Miscellaneous value.

FOSSIL FUEL SAVINGS

Heating Penalty if fossil fuel heated building (or if heating fuel is unknown):

$$\Delta Therms = \frac{(WattsBase - WattsEE)}{1{,}000} * ISR * Hours * - IFTherms$$

Where:

IFTherms = Lighting-HVAC Integration Factor for gas heating impacts; this factor represents the increased gas space heating requirements due to the reduction of waste heat rejected by the efficient lighting. Values are provided in the Referecne Table in Section 4.5. If unknown, use the Miscellaneous value.

MID-LIFE ADJUSTMENT

For Direct Install programs a mid-life adjustment should be applied after two years. To calculate the adjustment perform the following calculation:

$$\text{Mid-life adjustment} = \frac{(Standard\ LED\ Lamp\ wattage - Ultra\ Efficient\ Lamp\ Wattage)}{(Existing\ Replaced\ Lamp\ Wattage - Ultra\ Efficient\ Lamp\ Wattage)}$$

[1397] Negative value because this is an increase in heating consumption due to the efficient lighting.

4.6.Refrigeration End Use

4.6.1 Automatic Door Closer for Walk-In Coolers and Freezers

DESCRIPTION

This measure is for installing an auto-closer to the main insulated opaque door(s) of a walk-in cooler or freezer. The auto-closer must firmly close the door when it is within 1 inch of full closure.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure consists of the installation of an automatic, hydraulic-type door closer on main walk-in cooler or freezer doors. These closers save energy by reducing the infiltration of warm outside air into the refrigeration itself.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline condition is assumed to be a walk in cooler or freezer without an automatic closure.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The deemed measure life is 8 years.[1398]

DEEMED MEASURE COST

The deemed incremental measure cost, which includes labor costs, is $502 for a walk-in cooler or freezer.[1399]

LOADSHAPE

Loadshape C22 - Commercial Refrigeration

COINCIDENCE FACTOR

The measure has deemed kW savings therefore a coincidence factor does not apply.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Savings calculations are based on values from through SCE Workpaper SWCR005 – Auto-Closers for Refrigerated Storage Door. Savings are averaged across all California climate zones and vintages.[1400]

Annual Savings	kWh
Walk in Cooler	2,399
Walk in Freezer	6,949

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Annual Savings	kW
Walk in Cooler	0.621
Walk in Freezer	1.300

[1398] Measure life estimate is sourced from California DEER Ex-Ante Support Table – 2020, Auto-Closer for Walk-In Cooler/Freezer Doors (GrocWlkIn-DrClsr). For more detail, please see: "SupportTable_EUL2020.xlsx".
[1399] Commercial Refrigeration: Auto-Closer for Refrigerated Storage Door (SWCR005-02), California eTRM, November 16, 2020
[1400] Commercial Refrigeration: Auto-Closer for Refrigerated Storage Door (SWCR005-02), California eTRM, November 16, 2020. Energy savings are per cooler/freezer and represent an average of the modeled savings across all California climate zones.

FOSSIL FUEL SAVINGS

Natural gas savings are attributable to automatic door closers for refrigerated storage spaces. If the site is heated with natural gas as the primary fuel type, the following deemed fossil fuel savings can be claimed:[1401]

Annual Savings	Therms
Walk in Cooler	0.183
Walk in Freezer	0.516

4.6.2 Beverage and Snack Machine Controls

DESCRIPTION

This measure relates to the installation of new controls on refrigerated beverage vending machines, non-refrigerated snack vending machines, and glass front refrigerated coolers. Controls can significantly reduce the energy consumption of vending machine and refrigeration systems. Qualifying controls must power down these systems during periods of inactivity but, in the case of refrigerated machines, must always maintain a cool product that meets customer expectations. This measure relates to the installation of a new control on a new or existing unit. This measure should **not** be applied to ENERGY STAR[1402] qualified vending machines, as they already have built-in controls.

Vending machine categories are as defined[1403] below:

- Refrigerated Beverage Vending Machine: A commercial refrigerator that cools bottled and/or canned beverages and dispenses the bottled and/or canned beverages on payment. Bottled or canned beverages means a beverage in a sealed container.
    - Class A Machine: A refrigerated bottled and/or canned beverage vending machine that is not a combination vending machine and in which 25 percent or more of the surface area on the front side of the beverage vending machine is transparent.
    - Class B Machine: Any refrigerated bottled and/or canned beverage vending machine not considered to be Class A, and is not a combination vending machine.
- Combination Vending Machine: A bottled and/or canned beverage vending machine containing two or more compartments separated by a solid partition, that may or may not share a product delivery chute, in which at least one compartment is designed to be refrigerated, as demonstrated by the presence of temperature controls, and at least one compartment is not.
    - Combination A: Combination vending machine where 25 percent or more of the surface area on the front side of the beverage vending machine is transparent.
    - Combination B: Combination vending machine that is not considered to be Combination A.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be a standard efficiency refrigerated beverage vending machine, non-refrigerated snack vending machine, or glass front refrigerated cooler with a control system capable of powering down lighting and refrigeration systems during periods of inactivity.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline equipment is assumed to be a standard efficiency refrigerated beverage vending machine, non-refrigerated snack vending machine, or glass front refrigerated cooler without a control system capable of powering down lighting and refrigeration systems during periods of inactivity

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 5 years.[1404]

[1402] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[1403] Code of Federal Regulations at 10 CFR 431. Subpart Q §431.296.
[1404] Measure Life Study, prepared for the Massachusetts Joint Utilities, Energy & Resource Solutions, November 2005.

DEEMED MEASURE COST

The actual measure installation cost should be used (including material and labor), but the following control costs[1405] can be assumed for analysis purposes:

Refrigerated Vending Machine and Glass Front Cooler: $245

Non-Refrigerated Vending Machine: $233

LOADSHAPE

Loadshape C52 - Beverage and Snack Machine Controls

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 0.[1406]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = \Delta\text{kWhLighting} + \Delta\text{kWhRef BMC}$$

$$\Delta\text{kWhLighting} = \frac{\left((8760 - \text{OccHours}) * \text{WBulb}\right)}{1000}$$

$$\Delta\text{kWhRef BMC} = \text{MDEC} * (\text{SleepHours} / 24) * \text{Days}$$

Where:

OccHours = Average Annual Hours facility is occupied [1407]

= Actual, if unknown[1408] assume 3,379 hrs

W_{Bulb} = Wattage of bulb in Refrigerated Beverage Vending Machine.

= Actual. If unknown use 56.4 W[1409] for fluorescent T8 bulbs[1410] and 31.6 W[1411] for TLEDs.

MDEC = Maximum Daily Energy Consumption per Federal regulations[1412]. Refrigerated Volume of 21 (ft^3) used in the calculations[1413]. If unknown, assume Class B, post-2019[1414]:

[1405] Measure Data and Specifications for the "Vending and Beverage Merchandise Controller", from the California eTRM, last updated 12/27/2018. Measure cost + Labor cost. The refrigerated machine was an average of several types (Double, single and triple doors). *Please see file: SWAP011-01 MeasureDataSpec - Vending and Beverage Merchandise Controller r0.6.xlsm*

[1406] Assumed that the peak period is coincident with periods of high traffic diminishing the demand reduction potential of occupancy based controls.

[1407] Occupied hours of Use per IL TRM Section 4.5 Lighting, Fixture Annual Operating Hours.

[1408] If location is known, but hours are unknown, see IL TRM Section 4.5 Lighting, for list of various locations and Annual Hours.

[1409] See 3.4.5 LED Fixtures for the F32T8 Standard Lamp - 4 foot x 2 bulbs.

[1410] Per Houghton, D. 1996. "Refrigerated Vending Machines - Overlooked Devices Hold Opportunities for Efficiency, New Services." E Source Tech Update, TU-96-7, the typical backlit display for a refrigerated beverage vending machine consists of two five-foot linear fluorescent lamps." (PGE, SWAP011-01 Vending and Beverage Merchandise Controller measure, MeasureDataSpec file)

[1411] See 3.4.5 LED Fixtures for the TLED Lamp x 2 bulbs.

[1412] 10 CFR 431. Subpart Q §431.296 (a) & (b). https://www.ecfr.gov/current/title-10/section-431.296

[1413] U.S. Department of Energy (DOE), Office of Energy Efficiency and Renewable Energy, Federal Energy Management Program. (n.d.) "Purchasing Energy-Efficient Refrigerated Beverage Vending Machines." Updated January 2020.

[1414] Those standards are the most stringent and therefore savings would be conservative.

Class	Vintage	EQN	MDEC (kWh/d)
A	post-2019	0.052 * V + 2.43	3.52
B		0.052 * V + 2.20	3.29
Combination A		0.086 * V + 2.66	4.47
Combination B		0.111 * V + 2.04	4.37
A	pre-2019	0.055 * V + 2.56	3.72
B		0.073 * V + 3.16	4.69

SleepHours = Maximum hours of sleep mode per day.

= 4 hrs[1415]

Days = Operating Days/yr.

= 365

For example, adding controls to a Class B post-2019 Vintage refrigerated beverage vending machine in an unknown location:

$\Delta kWh = \Delta kWh_{ligthing} + \Delta kWh_{Ref\ BMC}$

$\Delta kWh_{ligthing}$ = (8760 – OccHours) * W_{Bulb}

= ((8760 – 3,379) * 72 W) / 1,000

= 387 kWh/yr

$\Delta kWh_{Ref\ BMC}$ = MDEC * SleepHours/24 * Days

= 3.29 * 4/24 * 365

= 200 kWh/yr

ΔkWh = 587 kWh/yr

4.6.3 Door Heater Controls for Cooler or Freezer

DESCRIPTION

By installing a control device to turn off door heaters when there is little or no risk of condensation, one can realize significant energy savings. There are two commercially available control strategies that achieve "on-off" control of door heaters based on either (1) the relative humidity of the air in the store, or (2) the "conductivity" of the door (which drops when condensation appears). In the first strategy, the system activates your door heaters when the relative humidity in your store rises above a specific setpoint, and turns them off when the relative humidity falls below that setpoint. In the second strategy, the sensor activates the door heaters when the door conductivity falls below a certain setpoint, and turns them off when the conductivity rises above that setpoint.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be a door heater control on a commercial glass door cooler or refrigerator utilizing humidity or conductivity control.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline condition is assumed to be a commercial glass door cooler or refrigerator with a standard heated door with no controls installed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[1416]

DEEMED MEASURE COST

The incremental capital cost, including labor costs, for a refrigeration door heater control, regardless of the control strategy, on a per door basis is $79.50 per cooler door and $90.77 per freezer door.[1417]

LOADSHAPE

Loadshape C51 - Door Heater Control

COINCIDENCE FACTOR[1418]

The summer peak coincidence factor for this measure is assumed to be 44%.[1419]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWH = kWbase * NUMdoors * ESF * BF * 8766$$

Where:

[1416] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.
[1417] Door heater control unit costs are based on historical cost data, specific to the state of Illinois, collected by Ameren. See reference "Door Heater Costs AIC.xlsx" for more detail.
[1418] Source partial list from DEER 2008.
[1419] The summer peak coincidence factor is sourced from; Cadmus, "Commercial Refrigeration Loadshape Project Final Report", Northeast Energy Efficiency Partnership, Regional Evaluation, Measurement, and Verification Forum, Lexington, MA, 2015 (table 39). The coincidence factor is based on the run-time profile of anti-sweat door heater controls, for all control types, for summer peak hours, and represents an average of the monitored reduced run time between heaters with and without controls.

kWbase = connected load kW for typical reach-in refrigerator or freezer door and frame with a heater.

= If actual kWbase is unknown, assume 0.230 kW for freezers and 0.066 kW for coolers.[1420]

NUMdoors = number of reach-in refrigerator or freezer doors controlled by sensor

= Actual installed

ESF = Energy Savings Factor; represents the percentage of hours annually that the door heater is powered off due to the controls.

= 45% for all control types [1421]

BF = Bonus Factor; represents the increased savings due to reduction in cooling load inside the cases, and the increase in cooling load in the building space to cool the additional heat generated by the door heaters. [1422]

Definition	Representative Evaporator Temperature Range, °F[1423]	Typical Uses	BF
Low	-35 to 0	Freezers for times such as frozen pizza, ice cream, etc.	1.50
Medium	0 – 20	Coolers for items such as meat, milk, dairy, etc	1.30
High	20 – 45	Coolers for items such as floral, produce and meat preparation rooms	1.30

8766 = annual hours of operation

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (\Delta kWH \,/\, 8766) * CF$$

Where:

CF = Summer Coincident Factor for the measure

= 0.44[1424]

4.6.4 Electronically Commutated Motors (ECM) for Walk-in and Reach-in Coolers / Freezers

DESCRIPTION

This measure is applicable to the replacement of an existing, uncontrolled, and continuously operating standard-efficiency shaded-pole evaporator fan motor in refrigerated display cases or fan coil in walk-ins.

This measure achieves savings by installing a more efficient motor, the result of which produces less waste heat that the cooling system must reject.

If applicable, savings from this measure may be claimed in combination with measure 4.6.6 Evaporator Fan Control for Electrically Commutated Motors.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure applies to the replacement of an existing standard-efficiency shaded-pole evaporator fan motor in refrigerated display cases or fan coil in walk-ins. The replacement unit must be an electronically commutated motor (ECM) with a minimum efficiency of 66%. If controls are added as part of the motor upgrade to reduce annual run time, additional savings may potentially be claimed using measure 4.6.6 Evaporator Fan Control.

DEFINITION OF BASELINE EQUIPMENT

The baseline is the existing shaded-pole motor(s) with no fan control operating 8760 hours continuously in a refrigerated display case or fan coil unit of a walk-in cooling unit.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years.[1425]

DEEMED MEASURE COST

The measure cost is assumed to be as follows, per motor, for a walk in cooler or walk in freezer:[1426]

Walk-In Type	Equipment Cost ($)	Labor $/ECM Motor	Total $ per motor
Cooler	$358.50	$63.80	$422.30
Freezer	$208.52	$63.80	$272.32
Unknown (average)	$283.51	$63.80	$347.31

LOADSHAPE

Loadshape C53 - Flat

COINCIDENCE FACTOR

The peak kW coincidence factor is 100%.

[1425] DEER, Work Paper PGE3PREF126 ECM for Walk-In Evaporator with Fan Controller Revision # 2

[1426] CA eTRM "ECM Retrofit for a Walk-in Cooler or Freezer" measure, supporting Cost Data (file = swcr004-02_cost_analysis.xlsx).

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = Savings\ per\ motor\ *\ motors$$

Where:

Savings per motor = based on the motor rating of the ECM motor:

Evaporator Fan Motor Rating (of ECM)	Annual kWh Savings/motor
16W	652
1/15 - 1/20HP	1,586
1/5HP	2,320
1/3HP	3,380
1/2HP	4,481
3/4HP	5,293

= If unknown, assume 1/15 HP, therefore 1,586 kWh saved / motor[1427]

motors = number of fan motors replaced

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh / Hours\ *\ CF\ *\ motors$$

Where:

ΔkWh = Gross customer annual kWh savings for the measure, as listed above

= If unknown, assume 1,586 kWh[1428]

Hours = Full Load hours per year

= 8760

CF = Summer Peak Coincident Factor

= 1.0

Other variables as defined above.

The following table provides the resulting kW savings (per motor), if unknown assume 0.181 kW saved / motor:[1429]

Evaporator Fan Motor Rating (of ECM)	Peak kW Savings/motor
16W	0.074
1/15 - 1/20HP	0.181
1/5HP	0.265
1/3HP	0.386
1/2HP	0.512
3/4HP	0.604

[1427] Default motor size for EC Evaporator was found to be ≤ 1/15 HP per the ComEd Standard Program data. See ECM Motor Size Supplement.xlsx.

4.6.5 ENERGY STAR Refrigerated Beverage Vending Machine

DESCRIPTION

ENERGY STAR[1430] qualified new and rebuilt vending machines incorporate more efficient compressors, fan motors, and lighting systems as well as low power mode option that allows the machine to be placed in low-energy lighting and/or low-energy refrigeration states during times of inactivity.

This measure was developed to be applicable to the following program types: TOS, NC .

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The refrigerated vending machine can be new or rebuilt but must meet the ENERGY STAR specifications, as outlined below.[1431]

A. Refrigerated Beverage Vending Machine: A commercial refrigerator that cools bottled and/or canned beverages and dispenses the bottled and/or canned beverages on payment. Bottled or canned beverages means a beverage in a sealed container.

a. Class A Machine: A refrigerated bottled and/or canned beverage vending machine that is not a combination vending machine and in which 25 percent or more of the surface area on the front side of the beverage vending machine is transparent.

b. Class B Machine: Any refrigerated bottled and/or canned beverage vending machine not considered to be Class A, and is not a combination vending machine

B. Combination Vending Machine: A bottled and/or canned beverage vending machine containing two or more compartments separated by a solid partition, that may or may not share a product delivery chute, in which at least one compartment is designed to be refrigerated, as demonstrated by the presence of temperature controls, and at least one compartment is not.

a. Combination A Machine: A combination vending machine where 25 percent or more of the surface area on the front side of the beverage vending machine is transparent.

b. Combination B Machine: A combination vending machine that is not considered to be Combination A.

DEFINITION OF BASELINE EQUIPMENT

The baseline vending machine is a standard unit.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The deemed lifetime of this measure is 14 years.[1432]

DEEMED MEASURE COST

The incremental cost of this measure is $500.[1433].

LOADSHAPE

Loadshape C22 - Commercial Refrigeration

COINCIDENCE FACTOR

It is assumed that controls are only effective during off-peak hours and so have no peak-kW savings.

[1430] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[1431] ENERGY STAR Program Requirements Specification for Refrigerated Beverage Vending Machines, Version 4.0

[1432] ENERGY STAR

[1433] ENERGY STAR

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Using the ENERGY STAR MDEC Equations, as specified in the above paragraph and the Baseline Equipment DOE Standards,[1434] the theoretical energy savings are calculated as:

$$\Delta\text{kWh} = (MDEC_{Baseline} - MDEC_{Efficient}) * Days$$

Where:

MDEC*Baseline* = Maximum Daily Energy Consumption calculated using the equation from the table below, specific for the baseline equipment class and the volume range

MDEC*Efficient* = Maximum Daily Energy Consumption calculated using the equation from the table below, specific for the ENERGY STAR Specification 4.0 equipment class and the volume range

Days = Days per year

= Actual. If unknown, assume 365.

Maximum Daily Energy Consumption (MDEC) equations for Baseline Equipment and ENERGY STAR equipment compliant with ENERGY STAR Specification V4.0 are outline in the table below:

Product Class	Refrigerated Volume Range (ft^3)	MDEC Equation (kWh/day) Federal Standard: Baseline	MDEC Equation (kWh/day) ENERGY STAR V4.0
Class A	11.5 - 38.5	0.052 * V + 2.43	0.04836 * V + 2.2599
Class B	21.8 - 30.5	0.052 * V + 2.20	0.04576 * V + 1.936
Combination A	9.7 - 16	0.086 * V + 2.66	0.07998 * V + 2.4738
Combination B	N/A	0.111 * V + 2.04	0.09768 * V + 1.7952

Where:

V = the refrigerated volume (ft^3) of the refrigerated bottled or canned beverage vending machine, as specified in Appendix C.[1435]

4.6.6 Evaporator Fan Control for Electrically Commutated Motors

DESCRIPTION

This measure is for the installation of controls for Electronically Commutated Motors in existing medium temperature walk-in coolers. The controller reduces airflow of the evaporator fans when there is no refrigerant flow.

This measure achieves savings by controlling the motor(s) to run at lower speeds (or shut off entirely) when there is no refrigerant flow, the result of which produces less waste heat that the cooling system must reject.

If eligible, this measure may be claimed in combination with 4.6.4 Electronically Commutated Motors (ECM) for Walk-in and Reach-in Coolers / Freezers.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The measure must control a minimum of 1/20 HP where fans operate continuously at full speed. The measure also must reduce fan motor power by at least 75% during the off cycle. This measure is not applicable if any of the following conditions apply:

- The compressor runs more than 4380 hours annually
- The evaporator fan does not run at full speed all the time
- The evaporator fan motor runs on poly-phase power
- Evaporator does not use off-cycle or time-off defrost.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the existing condition must be a reach-in or walk-in freezer or cooler with continuously running evaporator fans driven by Electrically Commutated Motors

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 13 years.[1436]

DEEMED MEASURE COST

The measure cost is assumed to be $69.69 (controller equipment) plus $92.06 (controller labor) = $161.75 per motor controlled.[1437]

LOADSHAPE

Loadshape C46 - Evaporator Fan Control

COINCIDENCE FACTOR

The measure has deemed kW savings therefore a coincidence factor does not apply.

Algorithm

CALCULATION OF SAVINGS

Savings are based on a measure created by Energy & Resource Solutions for the California Municipal Utilities Association[1438] and supported by a PGE workpaper. Note that climate differences across all California climate zones result in negligible savings differences, which indicates that the average savings for the California study should apply

[1436] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.
[1437] Source: DEER, Work Paper PGE3PREF126 ECM for Walk-In Evaporator with Fan Controller Revision # 2
[1438] See reference Excel files in TRM Reference Documents folder for derivation of TRM values.

equally as well to Illinois. Savings found in the aforementioned source are presented in combination with savings from an ECM upgrade, however for the purposes of this measure only those associated with the controller are considered.

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = Savings\ per\ motor\ *\ motors$$

Where:

Savings per motor = based on the motor rating of the ECM motor:

Evaporator Fan Motor Rating (of ECM)	Annual kWh Savings/motor
16W	198
1/15 - 1/20HP	293
1/5HP	856
1/3HP	1,419
1/2HP	2,126
3/4HP	3,209

motors = number of fan motors controlled

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = Peak kW savings per motor (as listed in the table below) * motors (as defined above)

Evaporator Fan Motor Rating (of ECM)	Peak kW Savings/motor
16W	0.023
1/15 - 1/20HP	0.033
1/5HP	0.098
1/3HP	0.162
1/2HP	0.243
3/4HP	0.366

4.6.7 Strip Curtain for Walk-in Coolers and Freezers

DESCRIPTION

This commercial measure pertains to the installation of infiltration barriers (strip curtains) on walk-in coolers or freezers. Strip curtains impede heat transfer from adjacent warm and humid spaces into walk-ins when the main door is opened, thereby reducing the cooling load. As a result, compressor run time and energy consumption are reduced. The engineering assumption is that the walk-in door is open for varying durations per day based on facility type, and the strip curtain covers the entire door frame. All algorithms and assumptions are based on prescriptive methodologies detailed by the Regional Technical Forum[1439], whose source calculations are outlined in ASHRAE's Refrigeration Handbook for calculating refrigeration load from infiltration by air exchange.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is a strip curtain at least 0.06 inches thick added to a walk-in cooler or freezer.[1440] The new strip curtain must cover the entire area of the doorway when the door is opened.

DEFINITION OF BASELINE EQUIPMENT

The baseline assumption is a walk-in cooler or freezer that previously had either no strip curtain installed or an old, ineffective strip curtain installed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 4 years.[1441]

DEEMED MEASURE COST

The incremental capital cost for this measure is $10.22/sq ft of door opening.[1442]

LOADSHAPE

Loadshape C22 - Commercial Refrigeration

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is 100%.[1443]

1439 Database for UES Measures, Regional Technical Forum, Strip Curtains, version 2.1, September 2019

[1440]Pennsylvania Public Utility Commission Technical Reference Manual, Volume 3: Commercial and Industrial Measures, State of Pennsylvania Act 129 Energy Efficiency and Conservation Program & Act 213 Alternative Energy Portfolio Standards, Revised February 2021 -- Chapter 3.5.8 Strip Curtains for Walk-in Freezers and Coolers.

[1441]DEER 2014 Effective Useful Life.

[1442] The reference for incremental cost is $10.22 per square foot of door opening (includes material and labor). 2008 Database for Energy-Efficiency Resources (DEER), Version 2008.2.05, "Cost Values and Summary Documentation", California Public Utilities Commission, December 16, 2008.

[1443] The summer coincident peak demand reduction is assumed as the total annual savings divided by the total number of hours per year, effectively assuming the average demand reduction is realized during the peak period. This is a reasonable assumption for refrigeration savings.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS[1444]

$$\Delta kWh = \Delta kWh/sq\ ft * A$$

Where:

ΔkWh/sq ft = Average annual kWh savings per square foot of infiltration barrier. Deemed values can be found in the table below

A = Doorway area in square feet.

= Actual. If the actual doorway area in square feet is unknown, then use the values found in the table below

Default Energy Savings and Door Area for Strip Curtains[1445]

Type	Pre-Existing Curtains	Energy Savings ΔkWh/sq ft	Doorway Area (sqft)
Supermarket - Cooler	Yes	40.9	21
Supermarket - Cooler	No	119.9	
Supermarket - Freezer	Yes	168.5	21
Supermarket - Freezer	No	494.3	
Convenience Store - Cooler	Yes	6.3	21
Convenience Store - Cooler	No	23.6	
Convenience Store - Freezer	Yes	10.0	21
Convenience Store - Freezer	No	33.2	
Restaurant - Cooler	Yes	6.2	21
Restaurant - Cooler	No	22.5	
Restaurant - Freezer	Yes	32.4	21
Restaurant - Freezer	No	114	
Refrigerated Warehouse	Yes	53.4	120
Refrigerated Warehouse	No	153.4	

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh\ /\ 8766 * CF$$

Where:

8766 = hours per year

[1444] The source algorithm from which the savings per square foot values are determined is based on Tamm's equation (an application of Bernoulli's equation) [Kalterveluste durch kuhlraumoffnungen. Tamm W,.Kaltetechnik-Klimatisierung 1966;18;142-144;] and the ASHRAE handbook [American Society of Heating, Refrigeration, and Air-Conditioning Engineers (ASHRAE). 2010. ASHRAE Handbook, Refrigeration: 13.4, 13.6].

[1445] Database for UES Measures, Regional Technical Forum, Strip Curtains, version 2.1, September 2019. Custom edits were made to the workbook in order for savings approach to align with this measure workpaper. The In-Service-Rate (described as the Removal Rate by the RTF workbook) was changed from 25% to 0%. Additionally, a 58% efficacy value was inputted for sites that had existing, but inefficient strip curtains prior to retrofit. This value is sourced from tracer gas measurements on over 100 walk-in refrigeration units during the California Public Utility Commission's (CPUC) evaluation of the 2006-2008 CA investor owned utility energy efficiency programs. The baseline curtain efficacy rates are taken from short-term monitoring of over 100 walk-in units. "Commercial Facilities Contract Group 2006-2008 Direct Impact Evaluation", CPUC, February 2010.

4.6.8 Refrigeration Economizers

DESCRIPTION

This measure applies to commercial walk in refrigeration systems and includes two components, outside air economizers and evaporator fan controllers. Economizers save energy by bringing in outside air when weather conditions allow, rather than operating the compressor. Walk-in refrigeration systems evaporator fans run almost all the time; 24 hrs/day, 365 days/yr. This is because they must run constantly to provide cooling when the compressor is running, and to provide air circulation when the compressor is not running. However, evaporator fans are a very inefficient method of providing air circulation. Installing an evaporator fan control system will turn off evaporator fans while the compressor is not running, and instead turn on an energy-efficient 35 watt fan to provide air circulation, resulting in significant energy savings. This measure allows for economizer systems with evaporator fan controls plus a circulation fan and without a circulation fan.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified. IECC code requires economizers in certain instances and therefore projects relying on code baseline definitions must verify eligibility.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure an economizer is installed on a walk in refrigeration system.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a walk-in refrigeration system without an economizer.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated life of this measure is 15 years.[1446]

DEEMED MEASURE COST

Installation costs can vary considerably depending on system size (larger systems may require multiple economizer units), physical site layouts (locating economizer intakes and ductwork), and controls elected. Therefore, actual site-specific costs should be used.

LOADSHAPE

Loadshape C22 - Commercial Refrigeration

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 0%.[1447]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Electric energy savings is calculated dependent on whether evaporator fans controls are installed.

With Fan Control Installed

$$\Delta kWh = [HP * kWhCond] + [((kWEvap * nFans) - kWCirc) * Hours * DCComp * BF] - [kWEcon * DCEcon * Hours]$$

[1446] Estimated life from DEER Work Paper PGE3PREF126.

[1447] The economizer is only assumed to run when the outside temperature is below 33F (a 38°F cooler setpoint and 5 degree economizer deadband). Therefore savings will not coincide with the summer peak period.

Without Fan Control Installed

ΔkWh = $[HP * kWhCond] - [kWEcon * DCEcon * Hours]$

Where:

HP = Horsepower of Compressor

= actual installed

kWhCond = Condensing unit savings, kWh/HP[1448]

Climate Zone (City based upon)	Hermetic / Semi-Hermetic	Scroll	Discus
1 (Rockford)	494	434	410
2 (Chicago/O'Hare)	423	372	352
3 (Springfield)	321	282	267
4 (Belleview)	230	202	191
5 (Marion)	136	119	113

Hours = Number of annual hours that economizer operates [1449]

Region (city)	Hours
1 (Rockford)	2,033
2 (Chicago/O'Hare)	1,806
3 (Springfield)	1,350
4 (Belleview)	1,112
5 (Marion)	752

DCComp = Duty cycle of the compressor

= 50% [1450]

kWEvap = Connected load kW of each evaporator fan

= If known, actual installed. Otherwise assume 0.126 kW[1451]

kWCirc = Connected load kW of the circulating fan

= If known, actual installed. Otherwise assume 0.035 kW[1452]

nFans = Number of evaporator fans

= actual number of evaporator fans

[1448] Savings table uses Economizer Calc_Revised052024.xls. Assume 5HP compressor size used to develop kWh/Hp value. No floating head pressure controls and compressor is located outdoors. Bin Data for IL zones uses TMYx data.

[1449] In the source TRM (VT) this value was 2,996 hrs based on 38° F cooler setpoint, Burlington VT weather data, and 5 degree economizer deadband. The IL numbers were calculated by using weather bin data for each location (number of hours < 38F at each location is the Hours value) from TMYx data.

[1450] A 50% duty cycle is assumed based on examination of duty cycle assumptions from refrigeration suppliers (35%-65%), Cooltrol (35%-65%), Natural Cool (70%), Pacific Gas & Electric (58%). Also, manufacturers typically size equipment with a built-in 67% duty factor and contractors typically add another 25% safety factor, which results in a 50% overall duty factor.

[1451] Based on a weighted average of 80% shaded pole motors at 175 watts and 20% PSC motors at 84 watts. Motor wattage and efficiency values referenced from Oak Ridge National Laboratory, "Permanent Magnet Synchronous Motors for Commercial Refrigeration: Final Report", 2019. Table 1, page xiv; Table 24, page 57.

[1452] Wattage of fan used by Freeaire and Cooltrol. This fan is used to circulate air in the cooler when the evaporator fan is turned off. As such, it is not used when fan control is not present.

DCEcon = Duty cycle of the economizer fan on days that are cool enough for the economizer to be working

= If known, actual installed. Otherwise assume 63%[1453]

BF = Bonus factor for reduced cooling load from reduction of waste heat generation as a result of running the evaporator fan less

= 1.3[1454]

kWEcon = Connected load kW of the economizer fan

= If known, actual installed. Otherwise assume 0.227 kW.[1455]

For example, adding an outdoor air economizer and fan controls in Rockford to a 5 hp hermetic compressor walk in refrigeration unit with 3 evaporator fans would save:

ΔkWh = [hp * kWhCond] + [((kWEvap * nFans) – kWCirc) * Hours * DCComp * BF] – [kWEcon * DCEcon * Hours]

= [5 * 494] + [((0.126 * 3) – 0.035) * 2033 *0.5 * 1.3] – [0.227 * 0.63 * 2033]

= 2633 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta\text{kW} = \Delta kWh \; / \; Hours \; * \; CF$$

Where:

CF = Summer Peak Coincidence Factor for the measure

= 0 [1456]

MEASURE CODE: CI-RFG-ECON-V08-240101

REVIEW DEADLINE: 1/1/2028

[1453] Average of two manufacturer estimates of 50% and 75%.

[1454] Bonus factor (1+ 1/3.5) assumes COP of 3.5, based on the average of standard reciprocating and discus compressor efficiencies with a Saturated Suction Temperature of 20°F and a condensing temperature of 90°F.

[1455] The 227 watts for an economizer is calculated from the average of three manufacturers: Freeaire (186 Watts), Cooltrol (285 Watts), and Natural Cool (218 Watts).

[1456] The economizer is only assumed to run when the outside temperature is below 33F (a 38°F cooler setpoint and 5 degree economizer deadband). Therefore savings will not coincide with the summer peak period.

4.6.9 Night Covers for Open Refrigerated Display Cases

DESCRIPTION

This measure is the installation of fitted covers on existing open-type refrigerated and freezer display cases that are deployed during the facility unoccupied hours. Night covers are designed to reduce refrigeration energy consumption by reducing the work done by the compressor. Night covers reduce the heat and moisture entry into the refrigerated space through various heat transfer mechanisms. By fully or partially covering the case opening, night covers reduce the convective heat transfer into the case through reduced air infiltration. Additionally, they provide a measure of insulation, reducing conduction into the case, and also decrease radiation into the case by blocking radiated heat from entering the refrigerated space.

DEFINITION OF EFFICIENT EQUIPMENT

Curtains or covers on top of open refrigerated or freezer display cases that are applied at least six hours (during off-hours) in a 24-hour period.

DEFINITION OF BASELINE EQUIPMENT

Refrigerated and freezer, open-type display case in vertical, semi-vertical, and horizontal displays, with no night cover.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is 5 years, based on DEER 2014.[1457]

DEEMED MEASURE COST

The incremental capital cost for this measure is $42 per linear foot of cover installed including material and labor.[1458]

LOADSHAPE

Loadshape 22: Commercial Refrigeration

COINCIDENCE FACTOR

4.6.10 High Speed Rollup Doors

DESCRIPTION

This measure entails the installation of High Speed Doors in refrigerated warehouses. High speed doors can save energy by lowering infiltration through a reduction in time that cooled spaces are exposed to ambient outdoor conditions. This in turn can lower the demand on refrigeration systems.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a High Speed Door installed on the loading dock doorway of a refrigerated space. The high speed door is assumed to act as a primary door. It should be noted that for high-traffic applications (about 45 door passages per hour, using the defaults for this measure) a custom analysis is necessary to ensure that high-speed rollup doors will provide savings, because strip curtains may outperform the high speed door, if no other open-door protection device is installed.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is existing strip curtains on doorways to a loading dock. During times of traffic, primary doors are left open, leaving just the strip curtains as open-doorway protection.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 16 years.[1464]

DEEMED MEASURE COST

The incremental measure cost is $150/sqft.[1465]

LOADSHAPE

Loadshape C22 - Commercial Refrigeration

COINCIDENCE FACTOR

The coincidence factor is assumed to be 1.00.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Electric savings consider the change in loading on the refrigeration system as well as the consumption of the drive on the high speed door. The following algorithms are based heavily on those derived and described in chapter 24 Refrigerated-Facility Loads of the ASHRAE Refrigeration Handbook.

$$\Delta kWh = \left(0.00008333 * q * D_f * \eta * [D_{tB}(1 - E_B) - D_{tE}(1 - E_E)] - D_{tM}\mathrm{M}\right) * t$$

Where:

0.00008333 = conversion from Btu/h to tons

q = sensible and latent refrigeration load for fully established flow, Btu/h

[1464] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.

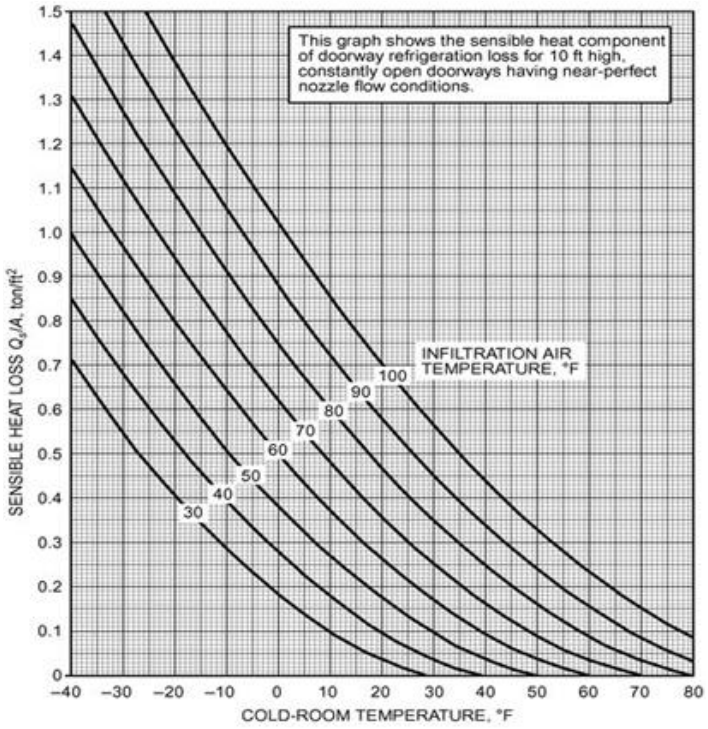
[1465] Rite Hite – Industrial High Speed Doors

$$= 3790 * W * H^{1.5} * \left(\frac{Q_s}{A}\right) * \left(\frac{1}{R_s}\right)$$

W = width of doorway, in feet. Custom input.

H = height of doorway, in feet. Custom input.

$\frac{Q_S}{A}$ = Sensible heat load of infiltration air per square foot of door way opening, as read from the following figure and dependent on infiltration air temperature and cooled space temperature. If unknown, infiltration temperature can be assumed to be 50° F,[1466] cooler temperature 35°F, and freezer temperature -10°F,[1467] resulting in values of 0.06 for a cooler and 0.5 for a freezer.



R_s = Sensible heat ratio of the infiltration air heat gain, as read or interpolated from the chart below or from a psychometric chart, dependent on temperature and relative humidity of infiltration air and cooled space temperature. If unknown, use the same assumptions as previously, with a warm space relative humidity value of 70%,[1468] resulting in values of 0.685 (interpolated) for coolers and 0.73 (interpolated) for freezers.

[1466] Taken to represent the overall annual average temperature in Illinois. TMY3 data for the five weather regions defined by the TRM indicate averages that fall within the range of 47.6 (Rockford) to 55.9 (Marion).
[1467] Refrigerated Warehouse, 2013 California Building Energy Standards, CODES AND STANDARDS ENHANCEMENT INITIATIVE (CASE), March 2011,
[1468] Taken to represent the overall annual average in Illinois. TMY3 data for the five weather regions defined by the TRM indicate averages that fall within the range of 69.1 (Springfield) to 72.1 (Rockford).

D_f = doorway flow factor. Equal to 0.8 for a doorway between a freezer and a dock and 1.1 for a doorway between a cooler and a dock.[1469]

η = Efficiency of refrigeration system (kW/ton). Custom input, if unknown assume 1.6 kW/ton for coolers and 2.4 kW/ton for freezers.[1470]

D_{tB} = decimal portion of time doorway is open in the baseline condition. If during facility operating hours, the primary doors are left open, leaving only open-doorway protective devices (e.g., strip curtains) as a barrier, this is considered 1.0. If primary doors are actively operated and do not remain open for the entire time the facility is in operation, refer to the following calculation.

$$D_{tB} = \frac{(P\ \theta_{pB}\ +\ 60\ \theta_{oB})}{3600\ \theta_d}$$

P = Number of passages through doorway per hour.

Θ_{pB} = Door open to close time in seconds.

Θ_{oB} = Time door remains open in minutes.

Θ_d = Period of time considered in hours, 1 hr.

D_{tE} = decimal portion of time doorway is open in the efficient condition.

$$D_{tE} = \frac{(P\ \theta_{pE}\ +\ 60\ \theta_{oE})}{3600\ \theta_d}$$

[1469] ASHRAE, "Refrigerated –Facility Loads", in Refrigeration Handbook 2014: ASHRAE, 2014, 24.7.

[1470] Professional judgement, in alignment with typical freezer and cooler performance found in the Michigan Energy Measures Database (MEMD).

P = Number of passages through doorway per hour. Custom input; assume 5.9 if unknown.[1471]

Θ_{pE} = Door open to close time in seconds. Custom input; assume 7.5 seconds if unknown.[1472]

Θ_{oE} = Time door remains open in minutes. Custom input; assume 3 minutes if unknown.[1473]

Θ_d = Period of time considered in hours, 1 hr.

D_{tM} = decimal portion of time high speed door motor is operational.

$$D_{tM} = \frac{P\ \theta_{pE}}{3600\ \theta_d}$$

Variables defined above.

E_B = effectiveness of baseline open-doorway protective device (strip curtains). Equal to 0.85.[1474]

E_E = effectiveness of efficient open-doorway protective device. Equal to 0, unless an additional protective device exists to limit infiltration during times when the high-speed door is open.

M = operating input power of the high speed door motor, in kW.

= Custom input; assume 1.49kW if unknown.[1475]

t = hours per year when primary doors to the cooled space are open.

= Custom input; assume 2,959 hrs/yr if unknown.[1476]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = (ΔkWh / t) * CF

Where

CF = Summer peak coincidence factor for this measure

= 1.0

All other variables as defined above.

[1473] Professional judgement.
[1474] ASHRAE, "Refrigerated –Facility Loads", in Refrigeration Handbook 2014: ASHRAE, 2014, 24.7
[1475] Rite Hite – Industrial High Speed Doors, product line commonly uses 2HP drives.
[1476] Based on a ComEd survey that obtained the number of hours per week certain building types operate. Warehouses had an average response of 55.6 and industrials had 58.2. Calculated by taking the simple average of the two and multiplying by 52 weeks/yr.
[1477] Assumes approximately 1 hour of maintenance, based on manufacturer product spec sheets.

MEASURE CODE: CI-RFG-HSRD-V03-220101

REVIEW DEADLINE: 1/1/2028

4.6.11 Q-Sync Motors for Walk-in and Reach-in Coolers/Freezers

DESCRIPTION

This measure is applicable to the replacement of an existing, uncontrolled, and continuously operating standard-efficiency shaded-pole, permanent split capacitor (PSC), and electronically commutated (EC) evaporator fan motors in reach-in refrigerated display cases as well as walk-in coolers and freezers.

This measure achieves energy savings by installing a more efficient Q-Sync motor in these scenarios (accompanied with replacement fan assembly as necessary). In addition to motor energy savings, the measure also results in less waste heat for the refrigeration equipment to reject and improves the power factor of the equipment.

This measure is limited to a typical reach-in refrigerated display case with the evaporator fan power of 9-12 Watts and walk-in coolers and freezers with the evaporator fan power of 38-50 Watts. In addition to the motor, replacement of the evaporator fan is necessary to ensure matching airflow is provided (because the fan's speed has been modified). Care must be taken by the installer to ensure airflows remain within the specified range, otherwise fan performance could suffer, causing reliability issues. Q-Sync motors are commonly purchased as a kit, which includes replacement fan blades and shrouds when replacement is necessary.

This measure was developed to be applicable to the following program types: RF, NC.[1478]

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The replacement unit must be a 9-12 Watt Q-Sync motor with a minimum of 73% motor efficiency or a 38-50 Watt Q-Sync motor with a minimum of 81% motor efficiency (as listed by manufacturer).

DEFINITION OF BASELINE EQUIPMENT

Depending on existing conditions, one of three baselines is chosen:

Baseline 1: existing shaded-pole motor(s) with no fan control operating 8760 hours continuously in a refrigerated reach-in display case, walk-in cooler, or walk-in freezer.

Baseline 2: EC motor with no fan control operating 8760 hours continuously in a refrigerated reach-in display case.

Baseline 3: existing PSC motor(s) with no fan control operating 8760 hours continuously in a walk-in cooler or freezer.

Baseline 4: blended baseline, consisting of a mix of shaded-pole motors and EC motors that are assumed to be present in retrofit project where accurate counts are unknown or difficult to determine. It is assumed that existing motors have no fan control and operate 8760 hours continuously in refrigerated reach-in display cases.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The deemed measure life is ten years.[1479]

DEEMED MEASURE COST

Actual measure costs should be used if available. If costs are not available, the following deemed measure cost can be used.[1480]

Measure	Material Unit (Each)	Material Cost / Unit	Labor Unit (Hours)	Labor Rate / Unit	Total Cost / Unit
9-12-watt Q-Sync motor (including replacement fan kit)	1	$52	0.25	$120	$82

[1478] Customers should be encouraged to check with the manufacturer to determine any impact on warranty of new equipment due to installing Q-sync fan/motor assemblies.
[1479] Based on communication with QM Power representative, April 16, 2018. See reference document "4.16.2018 Email.msg".
[1480] Based on communication with QM Power representative, April 24, 2018. See reference document "4.24.2018 Email.msg".

Measure	Material Unit (Each)	Material Cost / Unit	Labor Unit (Hours)	Labor Rate / Unit	Total Cost / Unit
38-50-watt Q-Sync motor (including replacement fan kit)	1	$50	0.50	$120	$110

Note: the material unit cost is based on a large-scale retrofit project.

COINCIDENCE FACTOR

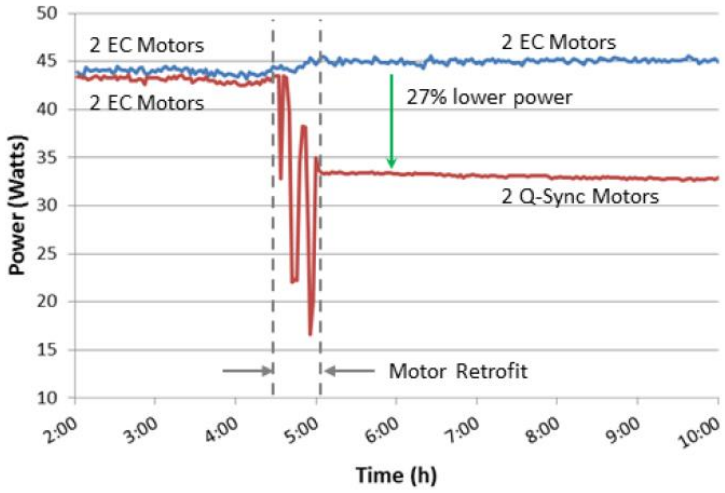
The peak kW coincidence factor is 100%

Algorithm

CALCULATION OF ENERGY SAVINGS

To determine the savings associated with the Q-Sync motor measure we utilized the field study results provided by Oak Ridge National Laboratory (ORNL)[1481] and Alternative Energy Systems Consulting (AESC)[1482] for refrigerated display cases, and the field study results provided by Slipstream[1483] and ORNL[1484] for walk-in coolers and freezers.

For refrigerated display cases, in 2015, ORNL conducted a side-by-side comparison of Q-Sync motors with EC motors in a 16 ft medium-temperature vertical multi-deck refrigerated display case at an Hy-Vee Supermarket in the Kansas City metropolitan area. A retrofit was done on the display case that contained four 12 W EC evaporator fan motors, two in each 8 ft section. Two existing EC motors in one of the 8 ft sections were replaced with two 12 W Q-Sync motors. The initial results show that Q-Sync motors consumed approximately 16.4 watts per motor, and EC motors consumed approximately 22.6 watts per motor.[1485]



[1481] Brian A. Fricke and Bryan R. Becker, "Q-Sync Motors in Commercial Refrigeration: Preliminary Test Results and Projected Benefits," Oak Ridge National Laboratory, September 2015.
[1482] M. Valmiki and Antonio Corradini, "Energy Savings of Permanent Magnet Synchronous Fan Motor Assembly Refrigerated Case Evaporators," Alternative Energy Systems Consulting, August 2016.
[1483] Xiaohui Zhou, et al, "Q-Sync Motor Performance in Walk-in Coolers and Freezers: Field Test for ComEd Emerging Technologies," Slipstream, March 2019.
[1484] Brian A. Fricke and Bryan R. Becker, "Permanent Magnet Synchronous Motors for Commercial Refrigeration: Final Report," Oak Ridge National Laboratory, July 2018.
[1485] Brian A. Fricke and Bryan R. Becker, "Q-Sync Motors in Commercial Refrigeration: Preliminary Test Results and Projected Benefits," Oak Ridge National Laboratory, September 2015.

In comparison, the 2011 study by Navigant and PNNL determined that a 12 w shade-pole motor 's actual power is 60.0 watts for use in commercial refrigration equipment at design condition,[1486] even though some manufacturers also pointed out that "there could be significant variations in efficiency between motors of the same type but different models." In the AESC study, the field test showed that the average input power for each of the 13 shaded pole motors retrofitted is 41.6 watts. As a compromise between the two studies, we use 50.0 watts as a representative number for shaded pole motors in our calculation. The average evaporator fan motor powers in refrigerated cases are summarized in the following table.

	Shaded-pole motor	PSC motor	Q-Sync motor
Average evaporator fan motor power in refrigerated display cases (watt)	50.0	22.6	16.4

For walk-in coolers and freezers, in 2019, Slipstream conducted a field study in three small businesses in Illinois retrofitting a total of 18 evaporator fan motors in 7 walk-in coolers or freezers. The average input power for each of the existing 16 shaded-pole motors was 131.6 watts, and 58.4 watts for each of the existing two PSC motors. The average input power for each of the 18 Q-Sync motors post-retrofit was 40.1 watts. In the ORNL 2018 field study on walk-in cooler/freezers in two supermarkets, the average input power for each of the existing 20 shaded-pole fan motors was 111.5 watts, and 61.4 watts for each of the existing 73 PSC motors. The average input power for each of the 93 Q-Sync motors post-retrofit was 36.6 watts. Combining both studies' results, the average powers for evaporator fan motors pre- and post-retrofit are listed in the following table:

	Shaded-pole motor	PSC motor	Q-Sync motor
Average evaporator fan motor power in walk-in coolers/freezers (watt)	120.4	61.3	37.2

For refrigerated display cases:

The electrical energy savings for replacing a shaded-pole motor with a Q-Sync motor in a retrofit project is calculated by the difference of the two motors demonstrated power draw multiplied by the annual operating hours. For med-temperature cases, T is 8,760 hours. For low-temp freezer cases, T is 8,578 hours considering daily 30-minute defrost cycles during which fans are not powered.[1487]

Motor energy savings (Baseline 1, med-temp, per motor)

= (50 W – 16.4 W) x 8760 hours / 1000 = 294.336 kWh

Motor energy savings (Baseline 1, low-temp, per motor)

= (50 W – 16.4 W) x 8578 hours /1000 = 288.221 kWh

The electrical energy savings for replacing an EC motor with a Q-Sync motor in a retrofit project is calculated by the difference of the two motors demonstrated power draw multiplied by the annual operating hours (8760 hours):

Motor energy savings (Baseline 2, med-temp, per motor)

= (22.6 W – 16.4 W) x 8760 hours / 1000 = 54.312 kWh

Motor energy savings (Baseline 2, low-temp, per motor)

[1486] NCI (Navigant Consulting Inc.) and PNNL (Pacific Northwest National Laboratory), "Preliminary Technical Support Document (TSD): Energy Conservation Program for Certain Commercial and Industrial Equipment: Commercial Refrigeration Equipment," Appliances and Commercial Equipment Standards, Building Technologies Program, Office of Energy Efficiency and Renewable Energy, US Department of Energy, Washington, D.C., 2011.

[1487] M M. Valmiki and Antonio Corradini, "Energy Savings of Permanent Magnet Synchronous Fan Motor Assembly Refrigerated Case Evaporators," Alternative Energy Systems Consulting, August 2016.

= (22.6 W – 16.4 W) x 8578 hours / 1000 = 53.184 kWh

The reduced motor power will also reduce refrigeration load. Assuming the power to drive the evaporator fan is converted to heat inside the display cases at 100% rate, the reduction in refrigeration system compressor power can be calculated using the following equation:

$$\Delta kWh_{refrigeration} = \frac{\Delta kWh_{motor}}{COP},$$

where COP is the Coefficient of Performance of refrigeration systems in the supermarket display cases. For med-temperature cases, the average COP is 2.5[1488]. For low-temp freezer cases, the average COP is 1.3.[1489]

The refrigeration energy savings can be calculated based on the above numbers:

Refrigeration energy savings (Baseline 1, med-temp, per motor) = 117.734 kWh

Refrigeration energy savings (Baseline 1, low-temp, per motor) = 221.708 kWh

Refrigeration energy savings (Baseline 2, med-temp, per motor) = 21.724 kWh

Refrigeration energy savings (Baseline 2, low-temp, per motor) = 40.910 kWh

The overall energy savings are the sums of the motor energy savings and the refrigeration energy savings:

Overall energy savings (Baseline 1, med-temp, per motor) = 412.070 kWh

Overall energy savings (Baseline 1, low-temp, per motor) = 509.929 kWh

Overall energy savings (Baseline 2, med-temp, per motor) = 76.036 kWh

Overall energy savings (Baseline 2, low-temp, per motor) = 94.094 kWh

For walk-in coolers and freezers:

The electrical energy savings for replacing a shaded-pole motor with a Q-Sync motor in a retrofit project is calculated by the difference of the two motors demonstrated power draw multiplied by the annual operating hours. For coolers, T is 8,760 hours. For freezers, T is 8,578 hours considering daily 30-minute defrost cycles during which fans are not powered.

Motor energy savings (Baseline 1, med-temp, per motor)

= (120.4 W – 37.2 W) x 8760 hours / 1000 = 728.832 kWh

Motor energy savings (Baseline 1, low-temp, per motor)

= (120.4 W – 37.2 W) x 8578 hours /1000 = 713.690 kWh

The electrical energy savings for replacing a PSC motor with a Q-Sync motor in a retrofit project is calculated by the difference of the two motors demonstrated power draw multiplied by the annual operating hours (8760 hours):

Motor energy savings (Baseline 3, med-temp, per motor)

= (61.3 W – 37.2 W) x 8760 hours / 1000 = 211.116 kWh

Motor energy savings (Baseline 3, low-temp, per motor)

= (61.3 W – 37.2 W) x 8578 hours / 1000 = 206.730 kWh

The reduced motor power will also reduce refrigeration load. Assuming the power to drive the evaporator fan is converted to heat inside the display cases at 100% rate, the reduction in refrigeration system compressor power can be calculated using the following equation:

[1488] Michael Deru, et al, "U.S. Department of Energy Commercial Reference Building Models of National Building Stock," NREL Report TP-5500-46861, February 2011.

[1489] Michael Deru, et al, "U.S. Department of Energy Commercial Reference Building Models of National Building Stock," NREL Report TP-5500-46861, February 2011.

$$\Delta kWh_{refrigeration} = \frac{\Delta kWh_{motor}}{COP},$$

where COP is the Coefficient of Performance of refrigeration systems in the supermarket display cases. For med-temperature cases, the average COP is 2.5. For low-temp freezer cases, the average COP is 1.3.

The refrigeration energy savings can be calculated based on above numbers:

Refrigeration energy savings (Baseline 1, med-temp, per motor) = 291.532 kWh

Refrigeration energy savings (Baseline 1, low-temp, per motor) = 548.992 kWh

Refrigeration energy savings (Baseline 3, med-temp, per motor) = 84.446 kWh

Refrigeration energy savings (Baseline 3, low-temp, per motor) = 159.023 kWh

The overall energy savings are the sums of the motor energy savings and the refrigeration energy savings:

Overall energy savings (Baseline 1, med-temp, per motor) = 1020.364 kWh

Overall energy savings (Baseline 1, low-temp, per motor) = 1262.682 kWh

Overall energy savings (Baseline 3, med-temp, per motor) = 295.562 kWh

Overall energy savings (Baseline 3, low-temp, per motor) = 365.753 kWh

ELECTRIC ENERGY SAVINGS

If the numbers of existing shaded-pole motors, EC motors to be retrofitted are known (Baseline 1,2, & 3):

ΔkWh = Overall annual savings per motor * Motors

Where overall energy savings per motor can is as speficied in the following table:

Evaporator Fan Motor Rating (of Q-Sync motor)	Baseline	Annual kWh Savings/motor
9-12W	shaded-pole motor, med-temp	412.070
9-12W	shaded-pole motor, low-temp	509.929
9-12W	EC motor, med-temp	76.036
9-12W	EC motor, low-temp	94.094
38-50W	shaded-pole motor, med-temp	1,020.364
38-50W	shaded-pole motor, low-temp	1,262.682
38-50W	PSC motor, med-temp	295.562
38-50W	PSC motor, low-temp	365.753

Motors = number of fan motors replaced

For refrigerated display cases, if the numbers of existing shaded-pole motors and EC motors are unknown in a retrofit project (Baseline 3):

$$\Delta kWh = [W_{med-temp}\,(W_{SPM}\,x\,S_{SPM-med} + W_{ECM}\,x\,S_{ECM-med}) + W_{low-temp}\,(W_{SPM}\,x\,S_{SPM-low} + W_{ECM}\,x\,S_{ECM-low})] * Motors$$

Motors = number of fan motors replaced

S = annual energy savings per motor, by type. Savings for each different type ($S_{SPM\text{-}med}$, $S_{SPM\text{-}low}$, $S_{ECM\text{-}med}$, $S_{ECM\text{-}low}$) can be looked up from the table above.

W = weighting factors. The weights for the medium-temperature and low-temperature applications ($W_{med\text{-}temp}$ and $W_{low\text{-}temp}$) should be calculated based on the actural numbers of motors in a retrofit project, and the sum of the two weights should equal to 1. If these weights cannot be accurately obtained, the estimated weights ($W_{med\text{-}temp}$* and $W_{low\text{-}}$

$_{temp}$*)[1490] from the table below can be used (the W_{SPM} and W_{ECM} numbers are slightly adjusted by +/-5% based on national averages in the 2015 ORNL study, reflecting some shaded pole motors may have been replaced with EC motors in the past few years).[1491]

Application	WSPM	WECM	Wmed-temp*	Wlow-temp*
Supermarkets	0.6	0.4	0.68	0.32
Other Food Retail Formats	0.8	0.2	0.68	0.32
Other Retail Categories	0.7	0.3	0.68	0.32
Restaurants and Bars	0.85	0.15	0.68	0.32
Beverage Vending Machines	0.85	0.15	0.68	0.32

For walk-in coolers and freezers, if the existing motor types are unknown in a retrofit project, it can be assumed they are PSC motors, as from industry survey in the 2018 ORNL study,[1492] 95% of the 38-50 watt evaporator fan motors are PSC motors.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$\Delta kW = \Delta kWh \ / \ Hours \ * \ CF$

Where:

ΔkWh = Gross customer annual kWh savings for the measure, as listed above

Hours = Full Load hours per year

= 8,766 (med-temp); 8,578 (low-temp)

CF = Summer Peak Coincident Factor

= 1.0

Other variables as defined above.

The following table provides the resulting kW savings (per motor):

Evaporator Fan Motor Rating (of Q-Sync motor)	Baseline	kW Savings/motor
9-12W	shaded-pole motor, med-temp	0.047
9-12W	shaded-pole motor, low-temp	0.059
9-12W	EC motor, med-temp	0.009
9-12W	EC motor, low-temp	0.011
38-50W	shaded-pole motor, med-temp	0.116
38-50W	shaded-pole motor, low-temp	0.147
38-50W	PSC motor, med-temp	0.034
38-50W	PSC motor, low-temp	0.043

4.6.12 Variable Speed Drive for Condenser Fans

DESCRIPTION

This measure is applicable to VFDs installed on condenser fan motors operating in supermarket refrigeration systems.

Where a baseline condenser motor load operates at a fixed-speed, VFDs generate energy and cost savings by modulating frequency and voltage to match the load on the condensers.[1496] Savings result from the resulting fan speed variation.

This measure is applicable to motors between 0.5 horsepower and 1.5 horsepower.

This measure was developed to be applicable to the following program types: RF, TOS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure applies to retrofitted installation of condenser fan motors in supermarkets where no ability to modulate frequency and voltage for fan-speed variation exits. Savings are based on the application of VFDs to baseline load conditions defined as pre-installation load compared to post-installation load.

DEFINITION OF BASELINE EQUIPMENT

The time-of-sale baseline is a new motor installed without a VFD or other methods of control. Retrofit baseline is an existing motor operating as is.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for VFD condenser fan applications is 15 years.[1497]

DEEMED MEASURE COST

Customer costs will be used when available. For motor sizes 0.5 to 1.5 HP the default measure cost is $1,170/HP. Custom costs must be gathered for other motor sizes.

LOADSHAPE

C22-commercial refrigeration.

COINCIDENCE FACTOR

The demand savings factor (DSF) is already based upon coincident savings, and thus there is no additional coincidence factor for this characterization.

Algorithm

CALCULATION OF ENERGY SAVINGS

Energy savings is based on a pre- and post-treatment test. The pre-treatment period being nearly three months in duration with post-treatment of a similar period. Both periods include significant average outdoor temperature (OAT) changes. Measurement of energy savings relies on regression of condenser fan energy use against ambient temperature. These estimates were made on each condenser using both pre- and post-VFD installation; comparison of the two yields savings.[1498]

[1496] Romberger, Jeff. Wed. "Chapter 18: Variable Frequency Drive Evaluation Protocol. The Uniform Methods Project: Methods for Determining Energy Efficiency Savings for Specific Measures". United States. doi:10.2172/1365710.

[1497] Efficiency Vermont TRM 3/16/2015 pp 19 for motor end use-variable frequency drives.

[1498] Pre- and post-VFD retrofit kWh consumption were derived from measurement of 14 condensers at 4 supermarkets in Rockford, Il. Annual savings in each Zone is the product of the number of hours in each 5-degree F Typical Meteorological Year

ELECTRIC ENERGY SAVINGS

Annual $\Delta kWh_{condenser} = No.fans * HP/fan * kWh\ savings/HP/Zone$

Zone	kWh savings/HP
1 (Rockford)	1,480
2 (Chicago)	1,500
3 (Springfield)	1,430
4 (Belleville)	1,430
5 (Marion)	1,480

For example, for a condenser with 5 fans, each rated at 1.5 HP in Chicago (Zone 2):

Annual $\Delta kWh_{condenser}$ = 5 * 1.5 * 1,500

= 11,250 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

N/A

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

Variable frequency drives, anecdotally, increase motor life because they allow for soft-start and soft shutdown. This would lead to O&M savings from replacing motors. Unfortunately, there is currently insufficient evidence to quantify this savings, so no deemed O&M savings can be claimed at this time.

MEASURE CODE: CI-RFG-VSC-V03-250101

REVIEW DEADLINE: 1/1/2029

temperature bin multiplied by the mean savings across the 14 condensers measured in the study. These estimates represent means from 10,000 simulations that include confidence intervals at the 90 percent level of +/-330, +/-330, +/-300, +/-320, and +/-310 for zones 1, 2, 3, 4, and 5, respectively. Detailed methods, assumptions, and calculations are found in "Variable Frequency Drive Energy Savings in Refrigeration Condensers Report. Slipstream, October, 9 2019"

4.6.13 Add Doors to Open Refrigerated Display Cases

DESCRIPTION

Open display cases are typically found in grocery and convenience stores and have been a preference of store owners because they allow customers a clear view and easy access to refrigerated products. This measure is retrofitting existing, open, refrigerated display cases by adding and installing doors. The baseline equipment is an open vertical or horizontal display case with no doors or covering. The efficient equipment is the installation of solid doors on the existing display case. Replacement of open display cases with new display cases with doors is not covered under this measure characterization.

Energy savings are based on air infiltration reduction from the addition of doors to the open display cases. The air infiltration reductions assume a reduced heat gain and subsequent reduced load on the refrigeration compressors. Both radiant and conduction heat losses were factored into the analysis as well. Energy savings are based on a per linear foot of display case.

Interactive HVAC energy savings were also included in the measure savings analysis. The HVAC interactive effects calculation assesses the measure's impact on the heating and cooling equipment. With adding a door to an open refrigerated display case, excess cold air leaking into the conditioned space no longer must be treated by the heating system, resulting in additive savings. Similarly, the reduction in cold air from the open refrigerated display case no longer supplements the efforts of the space cooling equipment, which results in an overall increase in its consumption.

High, medium, and low temperature cases are eligible for this measure; however, the measure assumptions detailed in this characterization are based on medium temperature display cases, with the installation of zero energy doors, as it was deemed the most likely candidate for participation in this measure. Open low temperature or freezer display cases are not common. If the retrofitted door has LED fixtures, it is recommended to leverage '4.5.4 LED Bulbs and Fixtures for quantifying savings and measure benefits.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is retrofitting an existing open, refrigerated, display case by adding doors.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is an open, refrigerated, display case without any covering.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 15 years.[1499]

DEEMED MEASURE COST

The incremental cost, which includes both material and labor, differs depending on whether or not the installed door is equipped with LED lighting. The estimated incremental cost for doors without LED lighting is $390 per linear foot. The incremental cost for doors with LED lighting is $419 per linear foot.[1500]

[1499] The measure life is sourced from the PG&E Workpaper, "Add Doors to Open Medium Temperature Cases – PGE3PREF116 R3", June 2019.

[1500] The incremental cost is sourced from the PG&E Workpaper, "Add Doors to Open Medium Temperature Cases – PGE3PREF116 R3", June 2019. The incremental cost for retrofitting new doors on existing refrigerated display cases is the material cost of the door and the labor cost required for installation. The material cost of the doors is $331 per linear foot with LED lighting and $301 per linear foot without LED lighting. And the installation cost is $88 per linear foot.

LOADSHAPE

Loadshape C03 - Commercial Cooling

Loadshape 22: Commercial Refrigeration

COINCIDENCE FACTOR

There are two components to the demand savings of this measure, one that impacts the refrigeration equipment itself, and another that has an interactive impact on the space cooling equipment. As a result, the measure details two summer coincidence peak demand factors.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = ((\Delta\text{HG} * \text{CL})/ (\text{EER} * 1000) * 8760) + (\text{MMBtu}_{\text{HVAC Cool}} * \text{CL} * (1 / \text{SEER2}) * 1000) - \text{kWh}_{\text{Night Covers}} - \text{kWh}_{\text{Added Lights}}$$

Where:

ΔkWh	= gross customer annual kWh savings
ΔHG	= Heat Gain, the decreased load or the reduced heat gain on the open refrigerated display case with the installation of a door (Btu/hr-linear foot)
	= 1,172 Btu/h-ft[1501] for vertical cases or 202.3 Btu/h-ft for horizontal cases[1502].
CL	= Case Length, refrigerated case length in feet
	= Actual
EER	= Energy Efficiency Ratio; display case compressor efficiency (Btu/hr-watt)
	= 11.36[1503]
1000	= Conversion from watts to kilowatts (W / kW)
8760	= Annual operating hours of the refrigerated display case[1504]
$\text{MMBtu}_{\text{HVAC Cool}}$	= Total cooling load increase on the HVAC equipment per linear foot of display case. Varies by location:[1505]

[1501] The change in heat gain is sourced as the typical value for a medium temperature vertical display case adding doors from the PG&E Workpaper, "Add Doors to Open Medium Temperature Cases - PGE3PREF116 R3", June 2019. The workpaper assumes a net reduction in heat gain with the installation of doors on open refrigerated display cases. The primary benefits account for the decrease in excess heat entering the display case from air infiltration. Radiation and conduction heat gains were also included in the derivation of this value. Additionally, the net heat gain has built in assumptions on how often the refrigerated case doors will be used and the display case accessed by customers and site associates, reducing some of the air infiltration benefits of the new door.

[1502] Average load difference between Hussmann open horizontal cases and lid horizontal cases across various configurations.

[1503] Average EER values were calculated as the average of standard reciprocating and discus compressor efficiencies, using a typical condensing temperature of 90°F and saturated suction temperatures (SST) of 20°F for medium temperature applications. The efficiency analysis and product review are sourced from the Efficiency Vermont TRM, which utilizes data from Emerson Climate Technology software. Medium temperature cases have an EER value of 11.36.

[1504] The measure assumes the baseline equipment is not employing night covers or any other covering but is in fact left open for the duration of its operation.

[1505] The MMBtu increase on the HVAC cooling equipment is based on an outdoor air temperature bin analysis, the total hours of operation of the cooling system, and the building's overall loss of additional cooling because of the installation of the doors on the open refrigerated display case. The analysis assumes a certain amount of conditioned air has to be treated to replace the air

Zone	$MMBtu_{HVAC\ Cool\ Vertical}$	$MMBtu_{HVAC\ Cool\ Horizontal}$
1 (Rockford)	-2.632	-0.454
2 (Chicago)	-2.763	-0.477
3 (Springfield)	-3.284	-0.567
4 (Belleville)	-3.254	-0.562
5 (Marion)	-3.335	-0.576

SEER2 = Seasonal Energy Efficiency Ratio; HVAC equipment operating efficiency (Btu/hr-watt) * Distribution Efficiency

= Actual, if unknown assume 11.1 SEER2.[1506]

$kWh_{Night\ Covers}$ = Reduction in energy savings if existing display case utilizes night covers (kWh/linear-ft)

= 0 if no night covers are deployed. See table below if display case uses night covers.

Display Case Description	Case Temperature Range (°F)	ΔkWh/ft reduction (= 9% reduction of electricity use[1507,1508])
Vertical Open, Remote Condensing, Medium Temperature	35°F to 55°F	131
Vertical Open, Remote Condensing, Low Temperature	0°F to 30°F	296
Vertical Open, Self-Contained Medium Temperature	35°F to 55°F	252

$kWh_{Added\ Lights}$ = Reduction in energy savings if new lighting is added to the case (kWh/linear-ft)

= 0 if no lighting is added, or if lighting is added but existing lighting is removed. If lighting is retrofit, determine case lighting savings using '4.5.4 LED Bulbs and Fixtures'.

= Actual installed equipment specifications or use case lighting values from '4.5.4 LED Bulbs and Fixtures'.

For example, a grocery store in Chicago installed zero energy doors on four open refrigerated cases that do not use night covers, which amounted to 12 linear feet of retrofitted display cases, savings the site:

ΔkWh = ((1172 * 12) / (11.36 * 1000) * 8760) + (-2.763 * 12 * (1 / 11.1) * 1000)

= 7858 kWh

previously cooled by the display case. Furthermore, the analysis assumes an increased load on the cooling system, at outdoor temperatures above 60°F. A 25% disabling factor was also applied to account for some of the cold air pouring out of the display case and subcooling the site's conditioned space, which will not trigger a thermostatic response from the HVAC equipment. For more information on the analysis used to derive the load increase on the HVAC cooling equipment per linear foot of display case, please see the 'HVAC IE' tab in the "IL TRM_Add Doors_Analysis_Mar 2021.xlsx".

[1506] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER value converted to SEER2 by multiplying by 0.95, and multiplied by 0.95 distribution efficiency.

[1507] Southern California Edison Refrigeration Technology and Test Center. Effects of the Low Emissivity Shields on Performance and Power Use of a Refrigerated Display Case. 1997. Southern California Edison, Rancho Cucamonga, CA. See '4.6.9 Night Covers' for more detail.

[1508] Technischer Uberwachungs-Verein Rheinland E.V. Laboratory test results for energy savings on refrigerated dairy case, conducted for Econofrost. See '4.6.9 Night Covers' for more detail.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (((\Delta HG * CL) / (EER * 1000) - kW_{Added\ Lights}) * CF_{Refrigeration}) + ((MMBtu_{HVAC\ Cool} / Hours_{Cool} * CL * (1 / SEER2) * 1000) * CF_{Cool})$$

Where:

$Hours_{Cool}$ = Total combined hours the site is providing cooling. Varies by location:[1509]

Zone	$Hours_{Cool}$
1 (Rockford)	2,994
2 (Chicago)	3,143
3 (Springfield)	3,736
4 (Belleville)	3,702
5 (Marion)	3,794

$kW_{Added\ Lights}$ = Reduction in demand savings if new lighting is added to the case (kW/linear-ft)

= 0 if no lighting is added, or if lighting is added but existing lighting is removed. If lighting is retrofit, determine case lighting savings using '4.5.4 LED Bulbs and Fixtures'.

= Actual installed equipment specifications or use case lighting values from '4.5.4 LED Bulbs and Fixtures'.

$CF_{Refrigeration}$ = Summer peak coincidence factor for the refrigerated display case

= 0.964

CF_{Cool} = Summer peak coincidence factor for the HVAC cooling system. This is the summer system peak coincidence factor for commercial dooling (during system peak hours)

= 0.913[1510]

FOSSIL FUEL SAVINGS

$$\Delta Therms = (MMBtu_{HVAC\ Heat} * CL * (1 / AFUE) * 10$$

Where:

$\Delta Therms$ = gross customer annual therms savings

$MMBtu_{HVAC\ Heat}$ = Total heating load decrease on the HVAC equipment per linear foot of display case. Varies by locations: [1511]

[1509] The total combined hours in which the site is providing cooling is based on an outdoor air temperature bin analysis, where the site is conditioning cold air at outdoor temperatures of 60°F and above. Weather data was sourced from TMY3 data for the specific locations. For more information on the derivation of these hours, please see 'HVAC IE' tab in the "IL TRM_Add Doors_Analysis_Mar 2021.xlsx" Night covers are not included in the peak demand savings algorithm because night covers are deployed at night, outside of the peak demand period.

[1510] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1511] The MMBtu decrease on the HVAC heating equipment is based on an outdoor air temperature bin analysis, the total hours of operation in which the site is providing heat, and the building's overall reduced heating load as a result of the installation of the doors on the open refrigerated display case. The analysis assumes a certain reduction of conditioned air that had to be treated to make up for the air previously cooled by the display case. The reduced heat gain on the refrigerated display case equals the reduced heat loss by the site and a heating load that no longer has to be provided by the HVAC system. Furthermore, the analysis assumes a decrease load on the heating system, at outdoor temperatures below 60°F. A 25% disabling factor was also applied to account for some of the cold air pouring out of the display case and subcooling the site's

Zone	$MMBtu_{HVAC\ Heat\ Vertical}$	$MMBtu_{HVAC\ Heat\ Horizontal}$
1 (Rockford)	5.068	0.875
2 (Chicago)	4.937	0.852
3 (Springfield)	4.416	0.762
4 (Belleville)	4.446	0.767
5 (Marion)	4.365	0.753

CL = Case Length, refrigerated case length in feet

= Actual

AFUE = Efficiency of heating system, including distribution losses.

Actual, if unknown assume 0.821.[1512]

10 = Conversion from MMBtu to therms

conditioned space, which will not trigger a thermostatic response from the HVAC equipment. For more information on the analysis used to derive the load decrease on the HVAC heating equipment per linear foot of display case, please see the 'HVAC IE' tab in the "IL TRM_Add Doors_Analysis_Mar 2021.xlsx".

[1512] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

4.6.14 Floating Head Pressure Control

DESCRIPTION

Installers conventionally design a refrigeration system to condense at a set pressure-temperature setpoint, typically 90 degrees. By installing a "floating head pressure control" condenser system, the refrigeration system can change condensing temperatures in response to different outdoor temperatures. This means that as the outdoor temperature drops, the compressor will not have to work as hard to reject heat from the cooler or freezer. This measure is for the application of floating head pressure controls for compressors ≤ 10HP and a condensing temperature set to 70ºF. This measure is strictly limited to single compressor systems.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified. IECC code requires economizers in certain instances and therefore projects relying on code baseline definitions must verify eligibility.

DEFINITION OF EFFICIENT EQUIPMENT

High efficiency is a refrigeration system with floating head pressure control.

DEFINITION OF BASELINE EQUIPMENT

The baseline is a refrigeration system without floating head pressure control.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 15 years[1513].

DEEMED MEASURE COST

Floating Head Pressure Control Costs, per Horsepower (condenser rating) are as follows ($/HP)[1514]:

Unit Type	Low Temperature (Freezer)	Medium Temperature (Refrigerator)	Unknown Temperature[1515]
Self- Contained Unit	$489	$534	$512
Remote Condensing Unit	$489	$534	$512
Unknown[1516]	$489	$534	$512

LOADSHAPE

Loadshape C22 - Commercial Refrigeration

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 0%, based on the fact that savings for this measure will occur during periods of coldest outdoor temperatures.

[1513] California DEER 2014 Effective Useful Life (EUL) table.

[1514] Costs are based on number of additional valves per condenser motor for different HP ratings and includes installation labor costs. Costs are averaged and shown on a per HP basis. See reference document ComGroceryFHPCSingleCompressor_v2_1.xlsm, worksheet 'CostData&Analysis,' blue highlighted cells. A comparison of prevailing wages in the Pacific Northwest showed high similarity to Illinois and therefore a simple inflation technique (using the US BLS's CPI Inflation Calculator, comparing the purchasing power of $1.00 in January 2012 to May 2021) was used to convert 2012$ to 2021$ (a multiplier of 1.19). Costs were updated for 2025 by comparing the costs from the above table (May 2021) to current inflation rates (March 2025).

[1515] Unknown values based on weighted average; 2010 ASHRAE Refrigeration Handbook, page 15.1 "Medium- and low-temperature display refrigerator line-ups account for roughly 68% and 32%, respectively, of a typical supermarket's total display refrigerators.

[1516] For unit type unknown, it is assumed 50/50 split of self-contained and remote condensing units.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = HP * kWh_{HP}$$

Where:

HP = Horsepower of Compressor

= actual installed

kWh_{HP} = Savings factor, kWh per horsepower of compressor rating. Per the tables below based on weather zone, condensing unit type, and temperature range[1517]:

Note: Self-contained condensing units assume heat is rejected to conditioned or semi-conditioned space. Therefore, outdoor air temperature is not considered a critical system variable resulting in identical savings across weather zones that are much lower compared to those realized by remove condensing units that reject heat to the outdoor environment.

Zone 1 (Rockford)

Unit Type	Low Temperature (Freezer)	Medium Temperature (Refrigerator)	Unknown Temperature
Self- Contained Unit	252	131	170
Remote Condensing Unit	482	451	461
Unknown	367	291	315

Zone 2 (Chicago)

Unit Type	Low Temperature (Freezer)	Medium Temperature (Refrigerator)	Unknown Temperature
Self- Contained Unit	252	131	170
Remote Condensing Unit	465	435	445
Unknown	358	283	307

Zone 3 (Springfield)

Unit Type	Low Temperature (Freezer)	Medium Temperature (Refrigerator)	Unknown Temperature
Self- Contained Unit	252	131	170
Remote Condensing Unit	403	377	385

[1517] Derived from RTF saving estimates for the NW climate zone and extrapolated to Illinois climate zones by using heating degree-days for a 65 degree F setpoint as established in Measure 4.4.37 Unitary HVAC Condensing Furnace measure. See reference file "fhp-savings-extrapolation-xlsx-Adjusted for Illinois.xlsx," 2021.

Unit Type	Low Temperature (Freezer)	Medium Temperature (Refrigerator)	Unknown Temperature
Unknown	327	254	278

Zone 4 (Belleville)

Unit Type	Low Temperature (Freezer)	Medium Temperature (Refrigerator)	Unknown Temperature
Self- Contained Unit	252	131	170
Remote Condensing Unit	321	301	307
Unknown	287	216	239

Zone 5 (Marion)

Unit Type	Low Temperature (Freezer)	Medium Temperature (Refrigerator)	Unknown Temperature
Self- Contained Unit	252	131	170
Remote Condensing Unit	328	307	314
Unknown	290	219	242

For example, a low temperature remote condensing unit in Chicago (Zone 2) with a 3-horsepower condenser would annually save:

$$\Delta kWh = 3 * 465$$
$$= 1,395 \text{ kWh}$$

SUMMER COINCIDENT PEAK DEMAND SAVINGS

There are no expected summer coincident peak demand savings for this measure.

FOSSIL FUEL SAVINGS

There are no expected fossil fuel gas savings for this measure.

REVIEW DEADLINE: 1/1/2030

4.6.15 Zero Energy Doors for Refrigerated Cases

DESCRIPTION

This measure was developed to reduce the use of electric resistance heaters that prevent the formation of condensation on refrigerated case doors. Standard refrigerated case doors include anti-condensation heaters in the frames, doors, or within the glass to prevent condensation from forming and obstructing view of refrigerated products. High efficiency, zero-energy doors are designed to prevent condensation using multiple layers of glass, low-conductivity filler gas, low-emissivity glass coatings, non-metallic spacers to separate glass panes, and/or non-metallic frames to prevent condensation. Energy savings from zero energy case doors are associated with the elimination of the anti-sweat heaters, as well as the resulting reduction of the load on the refrigeration and building cooling systems. This measure covers the replacement of standard doors with anti-sweat heaters with new zero energy doors on existing refrigerated cases.

This measure is not applicable to retrofitting existing open cases with new doors, a scenario that is covered by the existing measure 4.6.13, Adding Doors to Open Refrigerated Display Cases. It should be noted that the assumptions for measure 4.6.13 are based on installing zero energy doors on existing open medium temperature display cases.

This measure cannot be used in conjunction with measure 4.6.3, Door Heater Controls for Cooler or Freezer.

This measure may be used in conjunction with measure 4.5.4, LED Bulbs and Fixtures, if the installed door has integrated LED lighting, or new LED lighting is installed as part of a door retrofit.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is a refrigerated display case door designed to prevent condensation without the use of anti-sweat glass or frame heaters. Qualifying doors will have heat-reflective treated glass and have multiple glass panes with a with a low-conductivity gas fill.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a standard refrigerated display case door that uses anti-sweat glass and/or frame heaters to prevent condensation. Standard doors may have anti-sweat heater controls installed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The effective useful life for this measure is 12 years.[1518]

DEEMED MEASURE COST

The measure cost is assumed to be $601.80 (material cost per door) plus $132.78 (labor cost per door) = $734.58 per door.[1519]

LOADSHAPE

Loadshape C22 - Commercial Refrigeration

[1518] Effective measure life is per Southern California Edison Company, Work Paper SWCR002-02, "Low-Temperature Display Case Doors with no Anti-Sweat Heaters" Revision 2, April 2022

$$\Delta kWH = kWbase * NUMdoors * Hours * \%ASH * BF$$

Where

kWbase = connected load kW for standard freezer or cooler display case door with anti-sweat heaters. If actual kWbase is unknown, assume 0.230 kW for freezer and 0.066 kW for cooler cases.[1521]

NUMdoors = number of display case doors replaced or installed on new case

Hours = Hours per year, 8766

%ASH = percentage of annual hours anti-sweat heaters are operating. Assume 90.7% if no anti-sweat heater controls exist and 45.6% if existing case doors have functional anti-sweat heater controls installed.[1522] For installation of doors on new cases, assume that the baseline case uses anti-sweat heater controls[1523].

BF = Bonus Factor; represents the increased savings due to reduction in refrigeration load load and the reduction in building cooling load. Assume 1.5 for freezer cases and 1.3 for cooler cases.[1524]

For example, a bank of 10 reach-in cooler doors without anti-sweat heater controls are replaced with zero energy doors and would annually save:

ΔkWh = 0.066 * 10 * 8766 * 0.907 * 1.3

= 6,822 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (\Delta kWH \,/\, 8766) * CF$$

Where

CF = Summer peak coincident factor for measure, 66%

[1520] The coincidence factor reflects the elimination of anti-sweat heaters and is derived from the average load reduction from controlled heaters vs. non-controlled heater, see section 4.6.3.
[1521] kWbase/door are per Section 4.6.3 of the Illinois Statewide Technical Reference Manual, Version 12, p. 801
[1522] NEEP Refrigeration Loadshape Report. The Cadmus Group, Commercial Refrigeration Loadshape Project Final Report, Northeast Energy Efficiency Partnerships, Refional Evaluation, Measurement, and Verification Forum, Lexington, MA 2015 (p. 7)
[1523] This assumption is based on the efficiency requirements for display doors in the 2021 International Energy Conservation Code (IECC), C403.11.2.1 Performance Standards, which in new installations would make door heater controls necessary when using the kWbase assumptions above.

4.6.16 Door Gaskets for Walk-in and Reach-in Coolers and Freezers

DESCRIPTION

This measure characterizes the savings associated with installing new door gaskets on existing refrigerated cases and walk-in units where the existing gasket has been worn to the point where it no longer provides an effective seal. Tight fitting gaskets inhibit infiltration of warm, moist air into the cold refrigerated space, thereby reducing the cooling load. The reduction of moisture in the case also helps prevent frost on the evaporator coil. Frost buildup on the coil reduces the heat transfer effectiveness, reduces air passage, and increases energy use during the defrost cycle. Therefore, replacing defective door gaskets reduces compressor run time and improves the overall effectiveness of heat removal from a refrigerated cabinet or walk-in unit.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be a standard replacement gasket with the same profile and material composition as the original. The fit must be tight and seal properly upon installation with no visible gaps or tears.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline equipment is assumed to be a worn refrigeration gasket with visible damage that is allowing air to enter the unit with the door closed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 3 years[1525]

DEEMED MEASURE COST

Measure costs are based on values from a door gasket measure maintained by the RTF (Regional Technical Forum)[1526]. Original measure costs were adjusted for inflation from 2006 to 2024[1527].

Annual Savings	Cost/Door
Reach-In Cooler	$126
Reach-In Freezer	$156
Walk-In Cooler	$118
Walk -In Freezer	$177

LOADSHAPE

Loadshape C22 - Commercial Refrigeration

COINCIDENCE FACTOR

This measure has deemed kW savings therefore a coincidence factor does not apply.

Algorithm

CALCULATION OF ENERGY SAVINGS

Savings calculations are based on values from a door gasket replacement measure maintained by the RTF (Regional Technical Forum).[1528]

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = \Delta\text{kWhDoor} * \text{Doors}$$

Where:

ΔkWhDoor = Annual kWh savings per door from the table below

Annual Savings	ΔkWhDoor
Reach-In Cooler	248
Reach-In Freezer	243
Walk-In Cooler	204
Walk -In Freezer	347

Doors = Number of doors receiving new door gaskets

For example, a bank of 10 reach-in cooler doors have their old gaskets replaced with tight fitting and properly sealed new gaskets and would annually save:

ΔkWh = 248 * 10

= 2,480 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta\text{kW} = \Delta\text{kWDoor} * \text{Doors}$$

Where:

ΔkWDoor = Annual kW savings per door from the table below

Annual Savings	ΔkWDoor
Reach-In Cooler	.032
Reach-In Freezer	.032
Walk-In Cooler	.027
Walk -In Freezer	.045

FOSSIL FUEL SAVINGS

There are no expected fossil fuel gas savings for this measure.

4.7.Compressed Air End Use

4.7.1 VSD Air Compressor

DESCRIPTION

This measure relates to the installation of an air compressor with a variable frequency drive, load/no-load controls or variable displacement control. Baseline compressors choke off the inlet air to modulate the compressor output, which is not efficient. Efficient compressors use a variable speed drive on the motor to match output to the load. Savings are calculated using representative baseline and efficient demand numbers for compressor capacities according to the facility's load shape, and the number of hours the compressor runs at that capacity. Demand curves are as per DOE data for a Variable Speed compressor versus a Modulating compressor. This measure applies only to an individual compressor ≤ 200 hp. Only one compressor per compressed air distribution system is eligible.

This measure was developed to be applicable to the following program types: TOS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The high efficiency equipment is a compressor ≤ 200 hp with variable speed control.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is either an oil-flooded compressor ≤ 200 hp with inlet modulating with blowdown or load/no-load controls.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

13 years[1529]

DEEMED MEASURE COST

$$\text{IncrementalCost (\$)} = ((127 \times hp_{compressor}) + 1{,}446) \times 1.24$$[1530]

Where:

127 and 1,446[1531] = compressor motor nominal hp to incremental cost conversion factor and offset

$hp_{compressor}$ = compressor motor nominal

DEEMED O&M COST ADJUSTMENTS

N/A

LOADSHAPE

Loadshape C35 - Industrial Process

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

[1529] Department of Energy Technical Support Document.

[1530] Adjustment for inflation since incremental cost study is in $2008. The U.S. Bureau of Labor Statistic CPI Inflation Calculator was used to adjust $2008 (January) to $2021 (January). The resulting factor was 1.24. This adjustment was evaluated against current pricing of compressors (2021) and found to be a reasonable and appropriate.

[1531] Conversion factor and offset based on a linear regression analysis of the relationship between air compressor motor nominal horsepower and incremental cost, as sourced from the Efficiency Vermont Technical Reference Manual (TRM). Several Vermont vendors were surveyed to determine the cost of equipment.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = 0.9 \; x \; hp_{compressor} \; x \; HOURS \; x \; (CF_b \; - \; CF_e)$$

Where:

ΔkWh = gross customer annual kWh savings for the measure

$hp_{compressor}$ = compressor motor nominal hp

0.9[1532] = compressor motor nominal hp to full load kW conversion factor

HOURS = compressor total hours of operation below depending on shift

Shift	Hours	Description
Single shift (8/5)	1,976	7 AM – 3 PM, weekdays, minus some holidays and scheduled down time
2-shift (16/5)	3,952	7AM – 11 PM, weekdays, minus some holidays and scheduled down time
3-shift (24/5)	5,928	24 hours per day, weekdays, minus some holidays and scheduled down time
4-shift (24/7)	8,320	24 hours per day, 7 days a week minus some holidays and scheduled down time
Unknown / Weighted average[1533]	5,702	

CF_b = baseline compressor factor[1534]

Baseline Compressor	Compressor Factor (≤ 40 hp)[1535]	Compressor Factor (50 – 200 hp)[1536]
Modulating w/ Blowdown	0.890	0.863
Load/No-Load w/ 1 Gallon/CFM	0.909	0.887
Load/No-Load w/ 3 Gallon/CFM	0.831	0.811
Load/No-Load w/ 5 Gallon/CFM	0.806	0.786

[1532] Conversion factor based on Survey of CAGI data sheets from 200 compressors. See "IL TRM VSD Air Compressor – Supporting Information.xls" for more information.

[1533] Weighting of 16% single shift, 23% two shift, 25% three shift and 36% continual based on DOE evaluation of the Compressed Air Challenge, section 2.1.5 Facility Operating Schedules.

[1534] Compressor factors were developed using DOE part load data for different compressor control types as well as load profiles from 50 facilities employing air compressors less than or equal to 40 hp, as sourced from the Efficiency Vermont TRM.(The "variable speed drive" compressor factor has been adjusted up from the 0.675 presented in the analysis to 0.705 to account for the additional power draw of the VSD).

[1535] Compressor factors were developed using DOE part load data for different compressor control types as well as load profiles from 50 facilities employing air compressors less than or equal to 40 hp, as sourced from the Efficiency Vermont TRM. (The "variable speed drive" compressor factor has been adjusted up from the 0.675 presented in the analysis to 0.705 to account for the additional power draw of the VSD). See "IL TRM VSD Air Compressor – Supporting Information.xls" for more information.

[1536] Compressor factors for this size range were developed using DOE part-load data for different compressor control types as well as load profiles from 45 compressors and 20 facilities. This data comes from ComEd Custom and Insustrial Systems programs. The compressors were filtered to reflect only rotary screw compressors, between 50 and 200 hp, and operating a minimum of 4 hour per day, Additionally, compressors with clear and consistent baseload profiles were excluded from this analysis. See "IL TRM VSD Air Compressor – Supporting Information.xls" for more information.

CF_e = efficient compressor

=0.705 for units ≤ 40 hp[1537]

= 0.658 for units 50 – 200 hp

For example, a VSD compressor with 10 hp operating in a 1-shift facility would save

ΔkWh = 0.9 x 10 x 1,976 x (0.890 – 0.705)

= 3,290 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = $\Delta kWh \ / \ HOURS \ * \ CF$

Where:

CF = Summer peak coincidence factor for this measure

Shift	Coincidence Factor
Single shift (8/5)	0.59
2-shift (16/5)	0.95
3-shift (24/5)	0.95
4-shift (24/7)	0.95
Unknown / Weighted average[1539]	0.89

For example, a VSD compressor with 10 HP operating in a 1 shift facility would save

ΔkW = 3,290/1,976*0.59

= 0.98 kW

4.7.2 Compressed Air Low Pressure Drop Filters

DESCRIPTION

Low pressure drop filters remove solids and aerosols from compressed air systems with a longer life and lower pressure drop than standard coalescing filters, resulting in the ability to lower a compressed air systems pressure setpoints. This reduces the compressor work required resulting in energy savings.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is a low pressure drop filter with pressure drop not exceeding 1 psid when new and 3 psid at element change.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a standard coalescing filter with a pressure drop of 3 psid when new and 5 psid or more at element change

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

10 years [1540]

DEEMED MEASURE COST

The incremental cost for this measure is estimated to be $1,000 Incremental cost per filter.[1541]

LOADSHAPE

Loadshape C35 - Industrial Process

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (kW_{typical} \ x \ \Delta P \ x \ SF \ x \ Hours \ / \ hp_{typical}) \ x \ hp_{real}$$

Where:

$kW_{typical}$ = Adjusted compressor power (kW) based on typical compressor loading and operating profile. Use actual compressor control type if known:

[1540] Based on survey of manufacturer claims (Zeks, Van Air, Quincy), as recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.

[1541] Incremental cost research found in LPDF Costs. xlsx.

Compressor $kW_{typical}$

Control Type	$kW_{typical}$ [1542]
Reciprocating - On/off Control	70.2
Reciprocating - Load/Unload	74.8
Screw - Load/Unload	82.3
Screw - Inlet Modulation	82.5
Screw - Inlet Modulation w/ Unloading	82.5
Screw - Variable Displacement	73.2
Screw - VFD	70.8

= If the actual compressor control type is not known, use a weighted average based on the following market assumptions:

Control Type	Share %	$kW_{typical}$ [1543]
Market share estimation for load/unload control compressors	40%	74.8
Market share estimation for modulation w/unloading control compressors	40%	82.5
Market share estimation for variable displacement control compressors	20%	73.2
Weight average	-	77.6

ΔP = Reduction in pressure differential across the filter (psi)

=2 psi[1544]

SF =1% reduction in power per 2 psi reduction in system pressure is equal to 0.5% reduction per 1 psi, or a Savings Factor of 0.005[1545]

Hours = Compressor hours of operation below depending on shift

Shift	Hours	Description
Single shift (8/5)	1,976	7 AM – 3 PM, weekdays, minus three-weekday holidays and 10 days of scheduled down time
2-shift (16/5)	3,952	7AM – 11 PM, weekdays, minus three-weekday holidays and 10 days of scheduled down time
3-shift (24/5)	5,928	24 hours per day, weekdays, minus three-weekday holidays and 10 days of scheduled down time
4-shift (24/7)	8,320	24 hours per day, 7 days a week minus three-week day holidays and 10 days of scheduled down time
Unknown / Weighted average[1546]	5,702	

$hp_{typical}$ = Nominal hp for typical compressor = 100 hp[1547]

[1542] See "Industrial System Standard Deemed Saving Analysis.xls".
[1543] See "Industrial System Standard Deemed Saving Analysis.xls".
[1544] Assumed pressure will be reduced from a roughly 3 psi pressure drop through a filter to less than 1 psi, for a 2 psi savings
[1545] "Optimizing Pneumatic Systems for Extra Savings," Compressed Air Best Practices, DOE Compressed Air Challenge, 2010.
[1546] Weighting of 16% single shift, 23% two shift, 25% three shift and 36% continual based on DOE evaluation of the Compressed Air Challenge, section 2.1.5 Facility Operating Schedules.
[1547] Industrial System Standard Deemed Saving Analysis.xls

hp_{real} = Total hp of real compressors distibuting air through filter. This should include the total horsepower of the compressors that normally run through the filter, but not backup compressors.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh \ / \ Hours \ * \ CF$$

Where:

CF = Summer peak coincidence factor for this measure

Shift	Coincidence Factor
Single shift (8/5)	0.59

4.7.3 Compressed Air No-Loss Condensate Drains

DESCRIPTION

No-loss condensate drains remove condensate as needed without venting compressed air, resulting in less air demand and consequently better efficiency. Replacement or upgrades of existing no-loss drains are not eligible for the incentive.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is installation of no-loss condensate drains.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is installation of standard condensate drains (open valve, timer, or both)

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 13 years.[1549]

DEEMED MEASURE COST

The average equipment cost per drain is $194 with an installation labor cost of $50 for a total incremental cost $244 per drain.[1550]

LOADSHAPE

Loadshape C35 - Industrial Process

COINCIDENCE FACTOR

The coincidence factor equals 0.80[1551]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = CFM_{reduced} \; x \; kW_{CFM} \; x \; Hours$$

Where:

$CFM_{reduced}$ = Reduced air consumption (CFM) per drain

= 3 CFM[1552]

kW_{CFM} = System power reduction per reduced air demand (kW/CFM) depending on the type of compressor control:

[1549] Measure Life Study prepared for The Massachusetts Joint Utilities, Energy & Resource Solutions, 2005

[1550] Based on empirical project data from ComEd Comprehensive Compressed Air Study program and VEIC review of pricing data found in CAS Cost Data.xlsx.

[1551] DMI (2006). Impact Evaluation of 2004 Compressed Air Prescriptive Rebates. Prepared for National Grid; results analyzed in RLW Analytics (2006). Sample Design and Impact Evaluation Analysis for Prescriptive Compressed Air Measures in the Energy Initiative and Design 2000 Programs. Prepared for National Grid.

[1552] Reduced CFM consumption is based on a timer drain opening for 10 seconds every 300 seconds as the baseline. See "Industrial System Standard Deemed Saving Analysis.xls".

System Power Reduction per Reduced Air Demand[1553]

Control Type	kW / CFM
Reciprocating - On/off Control	0.184
Reciprocating - Load/Unload	0.136
Screw - Load/Unload	0.152
Screw - Inlet Modulation	0.055
Screw - Inlet Modulation w/ Unloading	0.055
Screw - Variable Displacement	0.153
Screw - VFD	0.178

Or if compressor control type is unknown, then a weighted average based on market share can be used: [1554]

Control Type	Share %	kW / CFM
Market share estimation for load/unload control compressors	40%	0.136
Market share estimation for modulation w/unloading control compressors	40%	0.055
Market share estimation for variable displacement control compressors	20%	0.153
Weighted Average		0.107

Hours = Compressed air system pressurized hours

=6136 hours[1555]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

4.7.4 Efficient Compressed Air Nozzles

DESCRIPTION

This measure is for the replacement of a standard air nozzle with a high-efficiency air nozzle used in a compressed air system. High-efficiency air nozzles reduce the amount of air required to blow off parts or for drying. These nozzles utilize the Coandă effect to pull in free air to accomplish tasks with significantly less compressed air. High-efficiency nozzles often replace simple copper tubes. These nozzles have the added benefits of noise reduction and improved safety in systems with greater than 30 psig.

DEFINITION OF EFFICIENT EQUIPMENT

The high-efficiency air nozzle must meet the following specifications:

1. High-efficiency air nozzle must replace continuous open blow-offs.
2. High-efficiency air nozzle must meet SCFM rating at 80psig less than or equal to:

Nozzle Diameter:	1/8”	1/4"	5/16”	1/2"
Max SCFM Rating @ 80psig:	11	29	56	140

3. Manufacturer’s specification sheet of the high-efficiency air nozzle must be provided along with the make and model.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a standard air nozzle.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is 15 years.[1557]

DEEMED MEASURE COST

The estimated incremental measure costs are presented in the following table:[1558]

Nozzle Diameter:	1/8”	1/4"	5/16”	1/2"
Average Incremental Cost:	$42	$57	$87	$121

LOADSHAPE

Loadshape C35 - Industrial Process

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (SCFM * SCFM\%Reduced) * kW/CFM * \%USE * Hours$$

[1557] PA Consulting Group (2009). Business Programs: Measure Life Study. Prepared for State of Wisconsin Public Service Commission.

[1558] Costs are from EXAIR’s website and are an average of nozzles that meet the flow requirements. Models include Atto Super, Pico Super, Nano Super, Micro Super, Mini Super, Super and Large Super nozzles. Accessed March 20, 2014.

Where:

SCFM = Air flow through standard nozzle. Use actual rated flow at 80 psi if known. If unknown, the table below includes the CFM by orifice diameter.[1559, 1560]

Orifice Diameter	SCFM
1/8”	21
1/4”	58
5/16”	113
1/2"	280

SCFM%Reduced = Percent in reduction of air loss per nozzle. Estimated at 50%.[1561]

kW/CFM = System power reduction per air demand (kW/CFM) depending on the type of air compressor found in table below:[1562]

Air Compressor Type	kW/CFM
Reciprocating – On/off Control	0.18
Reciprocating – Load/Unload	0.14
Screw – Load/Unload	0.15
Screw – Inlet Modulation	0.06
Screw – Inlet Modulation w/ Unloading	0.06
Screw – Variable Displacement	0.15
Screw - VFD	0.18

%USE = Percent of the compressor’s total operating hours that the nozzle is in use.

= Custom. If unknown assume 5%.[1563]

Hours = Compressed air system pressurized hours.

= Use actual hours if known. Otherwise assume values in table below:

Shift	Hours
Single Shift	1,976
Two Shifts	3,952
Three Shifts	5,928
Four Shifts or Continual Operation	8,320
Unknown / Weighted average[1564]	5,702

[1559] Review of manufacturer’s information.

[1560] Technical Reference Manual (TRM) for Ohio Senate Bill 221 “Energy Efficiency and Conservation Program” and 09-512-GE-UNC, October 15, 2009. Pages 170-171.

[1561] Conservative estimate based on average values provided by the Compressed Air Challenge Training Program, Machinery’s Handbook 25th Edition, and manufacturers’ catalog.

[1562] Calculated based on the type of compressor control. This assumes the compressor will be between 40% and 100% capacity before and after the changes to the system demand. See “Industrial System Standard Deemed Saving Analysis.xls”.

[1563] Assumes 50% handheld air guns and 50% stationary air nozzles. Manual air guns tend to be used less than stationary air nozzles, and a conservative estimate of 1 second of blow-off per minute of compressor run time is assumed. Stationary air nozzles are commonly more wasteful as they are often mounted on machine tools and can be manually operated resulting in the possibility of a long term open blow situation. An assumption of 5 seconds of blow-off per minute of compressor run time is used.

[1564] Weighting of 16% single shift, 23% two shift, 25% three shift and 36% continual based on DOE evaluation of the Compressed Air Challenge, section 2.1.5 Facility Operating Schedules.

For example, a ¼" diameter efficient air nozzle on a screw – VFD system, running on a three-shift schedule would save the following:

ΔkWh = (SCFM * SCFM%Reduced) * kW/CFM * %USE * Hours

= (58 * 50%) * 0.18 * 5% *5,928

= 1,547.2 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh \ / \ Hours \ * \ CF$$

Where:

ΔkWh = As calculated above.

CF = Summer peak coincidence factor

Shift	Coincidence Factor
Single Shift	0.59
Two Shifts	0.95
Three Shifts	0.95
Four Shifts or Continual Operation	0.95
Unknown / Weighted average[1565]	0.89

For examble, a ¼" diameter efficient air nozzle on a screw – VFD system, running on a three-shift schedule would save the following:

ΔkW = ΔkWh / Hours * CF

= 1,547.2 / 5,928 * 0.95

= 0.25 kW

4.7.5 Efficient Refrigerated Compressed Air Dryer

DESCRIPTION

An air dryer is an essential component in a compressed air system that prevents condensate from being deposited in the compressed air supply lines of a facility. If warm saturated compressed air is supplied directly to the plant, excess condensate will form in the compressed air supply lines. Uncontrolled condensate can damage demand-side tools and process equipment. Secondly, in an oil-flooded rotary screw compressor, the residual oil from compression can be carried along the supply lines potentially damaging process equipment. Industries that use compressed air for processes make use of various types of dryers including refrigerated dryers (both cycling and non-cycling). For this measure, three types of refrigerated air dryers will be considered: thermal mass, variable speed, and digital scroll. All these technologies offer better part load performance compared to non-cycling refrigerated dryers, thereby offering energy savings during periods when the dryer is not operating at peak capacity.

This measure was developed to be applicable to the following program types: TOS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

A new, high efficiency thermal mass dryer, variable speed dryer, or digital scroll dryer.

DEFINITION OF BASELINE EQUIPMENT

A standard non-cycling refrigerated compressed air dryer of comparable capacity.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is 13 years.[1566]

DEEMED MEASURE COST

The incremental capital cost for this measure is $6 per CFM.[1567]

LOADSHAPE

Loadshape C35 – Industrial Process

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = P_s * (EC50_{baseline} - EC50_{efficient}) * HOURS * CFM$$

Where:

P_s = Full flow specific power of the dryer

= 0.007 kW/CFM[1568] (for both baseline and efficient equipment)

[1566] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.

[1567] Analysis of material cost between cycling and non-cycling dryers according to online prices from Grainger. Cost provided is the average incremental cost when comparing non-cycling and cycling dryers of the same CFM capacity.

[1568] Compressed Air Challenge: Compressed Air Best Practice; "Cycling Air Dryers – Are Savings Significant?" Fox, Timothy J. and Marshall, Ron.

$EC50_{baseline}$ = Energy consumption ratio of baseline dryer at 50%[1569] inlet load capacity as compared to fully loaded operating conditions.[1570]

= 0.843

$ECF50_{efficient}$ = Energy consumption ratio of efficient dryer at 50% inlet load capacity as compared to fully loaded operating conditions.

= Dependent on efficient dryer type, refer to the following table:[1571]

Dryer Type	$EC50_{efficient}$
Thermal-Mass	0.729
VSD	0.501
Digital Scroll	0.551

HOURS = Compressed air system pressurized hours, depending on shift. If unknown, use weighted average. This value is the weighted average of facility owner responses from the DOE evaluation of the Compressed Air Challenge. Facility owners with compressed air systems were surveyed detailing the number of shifts their facilities operated.

Shift	Shift	Hours	Distribution of Facilities by Hours of Operation[1572]	Weighted Hours
Single Shift	7 AM – 3 PM, weekdays, minus some holidays and scheduled down time	1,976	16%	316
Two Shift	7AM – 11 PM, weekdays, minus some holidays and scheduled down time	3,952	23%	909
Three Shift	24 hours per day, weekdays, minus some holidays and scheduled down time	5,928	25%	1,482
Four Shifts or Continual Operation	24 hours per day, 7 days a week minus some holidays and scheduled down time	8,320	36%	2,995
			Total Weighted Average:	5,702

CFM = Cubic feet per minute, rated capacity of refrigerated dryer

= Assume 100% of actual rated capacity.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$\Delta kW = \Delta kWh / HOURS * CF$

Where:

CF = Summer peak coincidence factor, depending on shift. If unknown, use weighted average.

Shift	Coincidence Factor
Single Shift	0.59

[1569] Engineering judgement, based on the assumption that on average, compressed air systems will operate at 50% capacity.

4.7.7 Efficient Desiccant Compressed Air Dryer

DESCRIPTION

Compressed air is dried to reduce or eliminate condensation that can harm the compressed air system or end use equipment. For applications that require air to be dried below a dew point of 35°F,[1574] regenerative desiccant air dryers are typically used. Typically, regenerative desiccant dryers achieve pressure dew points as low as -40°F.

Regenerative desiccant dryers generally consist of two towers (or vertical tanks) filled with porous desiccant media. "Wet" compressed air flows through one tower, exiting as dried compressed air, while the other tower is dried out (or regenerated). This dryer alternates this process between towers to prevent compressed air flowing through saturated towers and damaging downstream equipment. The means of regeneration distinguishes the different types of regenerative dryer.

Heatless Desiccant Dryer: Uses compressed air ("purge air") to dry out the regenerating tower. The amount of purge air is typically between 15-20% of the dryer's rate flow (CFM), regardless of the flow rate that the compressor is supplying.[1575] This type of dryer alternates tower regeneration approximately every 5 minutes.[1576]

Heated Desiccant Dryer: Uses a combination of compressed purge air and heat for regeneration. The amount of purge air is typically 5-10% of the dryer's rate flow (CFM), regardless of the flow rate that the compressor is supplying.[1577] This type of dryer alternates tower regeneration approximately every 8 hours.[1578]

Externally Heated Blower Purge Dryer: Uses an external blower and heat source for regeneration. This type of dryer requires a small amount (2%) of purge air or ambient air to cool the tower after heating. This type of dryer alternates tower regeneration approximately every 8 hours.[1579] There is also a type of blower purge dryer called a zero-purge dryer that eliminates all compressed purge air.

The energy use of these dryers is primarily due to regeneration of the desiccant. Standard dryers come equipped with a fixed, timer regeneration control. However, the actual load on the dryer is variable. Optional dew point demand controls (DPDC) adjust the amount of regeneration to the moisture load on the dryer, reducing unnecessary purge energy.

This measure was developed to be applicable to the following program types: TOS, NC, ER.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is heated or externally heated by a blower purge desiccant dryer without dew point demand controls. Dryers installed on inlet modulation compressors do not qualify for this measure.

[1574] The dew point limitation of the most common refrigerant-type air dryer. Improving Compressed Air System Performance: A Sourcebook for Industry, US Department of Energy. Page 48. https://www.energy.gov/sites/prod/files/2016/03/f30/Improving%20Compressed%20Air%20Sourcebook%20version%203.pdf

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a heatless regenerative desiccant dryer without dew point demand controls.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The lifetime of this measure is 15 years.[1580]

DEEMED MEASURE COST

The incremental equipment cost for heated and blower purge regenerative desiccant dryers is $3/CFM and $12/CFM, respectively.[1581]

LOADSHAPE

Loadshape C35 – Industrial Process

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = CFM_{Dryer} * (P_{Base} -- P_{EE} * PRF) * HOU$$

Where:

CFM_{Dryer} = rated capacity of the dryer in cubic feet per minute (CFM)

P_{Base} = power requirement of the baseline heatless regenerative dryer (kW/CFM)

= $PF_{Heatless} * kW_{comp}$

$PF_{Heatless}$ = purge flow of heatless model (%)

= 15%[1582]

kW_{comp} = system power reduction per reduced air demand (kW/CFM) depending on the type of compressor control.[1583] If unknown, assume Screw – Load/Unload.

Air Compressor Type	ΔkW/CFM
Reciprocating – On/off Control	0.18
Reciprocating – Load/Unload	0.14
Screw – Load/Unload	0.15
Screw – Variable Displacement	0.15
Screw - VFD	0.18

[1580] Focus on Energy Evaluation Business Programs: Measure Life Study, p. 91-92. PA Consulting Group. August 25, 2009. https://focusonenergy.com/sites/default/files/bpmeasurelifestudyfinal_evaluationreport.pdf

[1581] Analysis of equipment cost between heatless, heated, blower purge dryers according to available online pricing. The capacity range considered was 250 – 1,500 CFM. Cost provided is the average incremental cost when comparing heated and blower purge dryers to baseline heatless dryers of the same CFM capacity. See "IL TRM Deissciant Dryers – Supporting Information.xls" file for more detail.

[1582] Typical estimates of purge flow for heatless dryers range from 15-20% of dryer rated capacity. 15% was selected as a conservative value.

[1583] Consistent with Air Nozzle measure, this assumes the compressor will be between 40% and 100% capacity before and after the changes to the system demand. See "Industrial System Standard Deemed Saving Analysis.xls".

Note: Dryers installed on inlet modulation compressors do not qualify for this measure.

P_{EE}	= power requirement of the energy efficient (heated or blower purge) regenerative dryer (kW/CFM)
	= (PF_{EE} * kW_{comp} + kW_{Heater} + kW_{Blower})
PF_{EE}	= purge flow of energy efficient model (%)[1584]
	= 7.5% for heated models
	= 2% for blower purge models (with compressed air cooling)
	= 0% for "zero-purge" blower purge models
kW_{Heater}	= average power of heater per CFM of dryer (kW/CFM)[1585,1586]
	= 0.007 kW/CFM for heated models
	= 0.013 kW/CFM for blower purge models
kW_{Blower}	= average power of blower per CFM of dryer (kW/CFM)[1587]
	= 0 kW/CFM for heated models
	= 0.003 kW/CFM for blower purge models
PRF	= purge reduction factor
	= Assume 50% for heatless desiccant dryers%[1588]
	= Assume 60% for externally heated or heated blower purge desiccant dryers[1589]
HOU	= compressor total hours of operation below depending on shift

[1584] Lessons Learned: Saving Energy Costs with Heated Blower Purge Desiccant Dryers, Marshall, Ron. https://airbestpractices.com/system-assessments/air-treatmentn2/lessons-learned-saving-energy-costs-heated-blower-desiccant-dry-0

[1585] Based on a review of data sheets from six manufacturers. These values reflect average heater kW and not nominal heater kW. The heater operation will vary based on moisture load to the dryer. See "IL TRM Deisscant Dryers – Supporting Information.xls" file for more detail.

[1586] The heater operation will be controlled by temperature to avoid overheating the desiccant media. Lessons Learned: Saving Energy Costs with Heated Blower Purge Desiccant Dryers, Marshall, Ron. https://airbestpractices.com/system-assessments/air-treatmentn2/lessons-learned-saving-energy-costs-heated-blower-desiccant-dry-0

[1587] Based on a review of data sheets from six manufacturers. These values reflect average blower kW and not nominal blower kW. The blower operation will in many cases vary based on moisture load to the dryer. See "IL TRM Deisscant Dryers – Supporting Information.xls" file for more detail.

[1588] "For heatless desiccant dryers, the reduction in purge tends to be proportional only to the reduction of flow, not the reduction in moisture load due to the lower inlet temperatures." The 50% value is based on the TRM's assumption of a 50% dryer load factor used Illinois TRM Measure 4.7.5. Marshall, Ron. 4.7.8 Desiccant Dryer Dew Point Demand Controls

DESCRIPTION

Compressed air is dried to reduce or eliminate condensation that can harm the compressed air system or end use equipment. For applications that require air to be dried below a dew point of 35°F,[1592] regenerative desiccant air dryers are typically used. Typically, regenerative desiccant dryers achieve pressure dew points as low as -40°F.

Regenerative desiccant dryers generally consist of two towers (or vertical tanks) filled with porous desiccant media. "Wet" compressed air flows through one tower, exiting as dried compressed air, while the other tower is dried out (or regenerated). This dryer alternates this process between towers to prevent compressed air flowing through saturated towers and damaging downstream equipment. The means of regeneration distinguishes the different types of regenerative dryer.

The energy use of these dryers is primarily due to regeneration of the desiccant. Standard dryers come equipped with a fixed, timer regeneration control. However, the actual load on the dryer is variable. Dew point demand controls (DPDC) adjust the amount of regeneration to the load on the dryer, reducing unnecessary purge energy. DPDC can be retrofit on existing desiccant dryers or integrated in new desiccant dryers.

Heatless Desiccant Dryer: Uses compressed air ("purge air") to dry out the regenerating tower. The amount of purge air is typically between 15-20% of the dryer's rate flow (CFM), regardless of the flow rate that the compressor is supplying.[1593] This type of dryer alternates tower regeneration approximately every 5 minutes.[1594]

Heated Desiccant Dryer: Uses a combination of compressed purge air and heat for regeneration. The amount of purge air is typically 5-10% of the dryer's rate flow (CFM), regardless of the flow rate that the compressor is supplying.[1595] This type of dryer alternates tower regeneration approximately every 8 hours.[1596]

Externally Heated Blower Purge Dryer: Uses an external blower and heat source for regeneration. This type of dryer requires a small amount (2%) of purge air or ambient air to cool the tower after heating. This type of dryer alternates tower regeneration approximately every 8 hours.[1597] There is also a type of blower purge dryer called a zero purge dryer that eliminates all compressed purge air.

This measure was developed to be applicable to the following program types: RF

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is a heatless, externally-heated, or blower purge regenerative desiccant dryer with dew point demand controls. The controls should be able to respond to changes in flow and moisture loading. Dryers installed on inlet modulation compressors do not qualify for this measure.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a heatless, externally-heated, or blower purge regenerative desiccant dryer without dew point demand controls.

4.7.9 Compressed Air Heat Recovery

DESCRIPTION

Air compressors are inherently inefficient, converting 80 to 93% of the electrical input energy into heat.[1609] Recovering this wasted heat for useful purposes is one method for reducing facility-level energy use. Typical air compressor heat recovery involves ducting air-cooled air compressor exhaust for space heat. Recovered heat can also be used for process heating, water heating, and boiler makeup water heating, but this workpaper only addresses the most common scenario.

This measure was developed to be applicable to the following program types: RF, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is an air-cooled air compressor that is ducted for heat recovery during the heating season. The ducting must include a thermostat that controls the heat recovery based on whether heating is needed.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an air-cooled air compressor whose exhaust is ducted to the outdoors or to a space where heat is not needed (e.g., compressor room, unoccupied space).

[1615] These values reflect a ratio of the hours below a heating balance point over 8,760. The heating balance point is assumed to be 55°F. The data source is TMY3 data. See "Compressed Air Heat Recovery – Supporting Info" file for derivation.
[1616] 80% is the federal minimum efficiency of gas-fired unit heaters. Unit heaters are a common heat source in industrial and manufacturing settings, where compressed air is likely to be in place.

4.7.10 Compressed Air Storage Receiver Tank

DESCRIPTION

Using an air receiver or storage tank will buffer the air demands of the system on the compressor, thus eliminating short cycling. Although a load/no-load compressor unloads in response to lowered demand, it does so over a period of time to prevent lubrication oil from foaming. Therefore, reducing the number of cycles reduces the number of transition times from load to no-load and saves energy.

To qualify for this measure an existing load/no-load compressor with a 1 gal/cfm storage ratio or a modulating w/ blowdown compressor must be replaced with a load/no-load compressor with an improved storage capacity and ratio.

This measure was developed to be applicable to the following program types: RF, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is an oil-flooded load/no-load compressor with an improved storage capacity and ratio compared to the existing system. The cfm should reflect the rated capacity (in cfm) of all active compressors. If that value cannot be determined, compressor power can be converted to capacity using the rule-of-thumb of 4.5 cfm/hp.[1617]

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an oil-flooded load/no-load compressor with a 1 gal/cfm storage ratio or a modulating w/ blowdown compressor.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

10 years

DEEMED MEASURE COST

Incremental cost ($) = 4.67 * ($Tank_E$ – $Tank_B$)[1618]

Where:

4.67 = air receiver tank size, in gallons, to equipment cost conversion factor

$Tank_E$ = efficient tank size (gallons)

$Tank_B$ = baseline tank size (gallons)

LOADSHAPE

Loadshape C35 – Industrial Process

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

[1617] The 4.5 cfm/hp rule of thumb is based on a rotary screw compressor delivering 4 to 5 cfm per 1 hp, “Relationship Between Pressure and Flow”, Compressed Air System Best Practices, Industrial Utility Efficiency.

4.7.11 Reduce Compressed Air Setpoint

DESCRIPTION

This measure characterizes the energy savings associated with reducing the compressed air pressure setpoint. A lower setpoint pressure results in the reduction of work requirements on the compressor resulting in energy savings. The energy savings assumptions are based on compressors operating at 100 psi.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment must meet the following requirements:

Compressor setpoint must be decreased
Specification and location of compressor must be known and verifiable

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an air compressor with a pressure setpoint higher than necessary (line pressure more than 115% of the highest end use requirement).

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 5 years.[1625]

DEEMED MEASURE COST

The incremental cost is assumed to be $0.

LOADSHAPE

Loadshape C35 – Industrial Process

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = (kW_{typical} * \Delta P * SF * Hours / hp_{typical}) * hp_{real}$$

Where:

ΔkWh = gross customer annual kWh savings for the measure

$kW_{typical}$ = adjusted compressor power (kW) based on typical compressor loading and operating profile. Use actual compressor control type if known:

[1625] Based on value from ComEd Operational Efficiency CY2018 Impact Evaluation.

Control Type	$kW_{typical}$ [1626]
Reciprocating - On/off Control	70.2
Reciprocating - Load/Unload	74.8
Screw - Load/Unload	82.3
Screw - Inlet Modulation	82.5
Screw - Inlet Modulation w/ Unloading	82.5
Screw - Variable Displacement	73.2
Screw - VFD	70.8

= if the actual compressor control type is not known, use a weighted average based on the following market assumptions:

Control Type		Share %	$kW_{typical}$ [1627]
Market share estimation for load/unload control compressors		56%	74.8
Market share estimation for modulation w/unloading control compressors		27%	82.5
Market share estimation for variable displacement control compressors		17%	73.2
Weight average	-	76.6	

ΔP = reduction in pressure differential between efficient and base case (psi)

= actual

SF = 1% reduction in power per 2 psi reduction in system pressure is equal to 0.5% reduction per 1 psi, or a Savings Factor of 0.005[1628]

HOURS = compressor total hours of operation below depending on shift

Shift	Hours	Description
Single shift (8/5)	1,976	7 AM – 3 PM, weekdays, minus some holidays and scheduled down time
2-shift (16/5)	3,952	7AM – 11 PM, weekdays, minus some holidays and scheduled down time
3-shift (24/5)	5,928	24 hours per day, weekdays, minus some holidays and scheduled down time
4-shift (24/7)	8,320	24 hours per day, 7 days a week minus some holidays and scheduled down time
Unknown / Weighted average[1629]	5,702	

$hp_{typical}$ = nominal hp for typical compressor

4.7.12 AODD Pump Controls

DESCRIPTION

Diaphragm pumps are widely used for their numerous advantages, such as simplicity, serviceability, and durability. These pumps can tolerate fluids that are corrosive, viscous, or contain a significant portion of entrained solids (E.g., effluent and slurries). Diaphragm pumps can be driven by compressed air or electric motors. Air-operated double diaphragm (AODD) pumps are estimated to be present in up to 85-90% of manufacturing plants in the US.[1632] The intrinsic simplicity of AODDs allow them to have significantly lower upfront material costs than electric motor-driven diaphragm pumps since there is no electric motor.

Typically, AODDs are operated at a fixed capacity and do not have a controller attached. In this scenario, the pump consumes compressed air continuously when operating. An electronic stroke controller can reduce the amount of air that the AODD pump consumes while operating. This controller synchronizes the compressed air release with the pump so that the diaphragm experiences a burst of air rather than a continuous stream. This reduces the air consumption and noise generation of the pump. This technology increases the pressure variance experienced by the pump; however, the overall impact on fluid flow is negligible.[1633]

Typically, this technology is limited to larger AODD pump sizes (≥ 2”), higher pressures (≥ 60 psig) and applications with longer operation times. This technology might not be applicable for systems with highly viscous fluids.

This measure was developed to be applicable to the following program types: RF, TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is an AODD pump with an electronic stroke optimizing control.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is an AODD pump operating at a fixed capacity.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

10 years[1634]

DEEMED MEASURE COST

Total cost is $1,150. The material cost for this type of control is $950.[1635] Labor is $200, based on estimated time of 2 hours and $100 per hour rate.[1636]

LOADSHAPE

Loadshape C35 – Industrial Process

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

Algorithm

[1632] Hank Van Ormer. “Study Proves Potential Energy Savings of AODD Pump Controls,” Compressed Air Best Practices. https://www.airbestpractices.com/system-assessments/end-uses/study-proves-potential-energy-savings-aodd-pump-controls

[1633] “Diaphragm Pump Controller Performance Project Report,” Purdue School of Engineering and Technology. January 12, 2015.

[1634] This is an estimated based on lifetimes of similar electronic controls. HVAC controls generally have a 15-year EUL but are typically in less demanding environments than industrial pumping applications (e.g., manufacturing, wastewater treatment, etc.). For this reason, a more conservative value of 10 years was selected.

[1636] Engineering judgement.

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = CFM_{AODD} * kW_{Comp} * Hours * SF$$

Where:

CFM_{AODD} = Rated flow of the AODD (CFM). Use actual, if known.

If unknown, see below for guidance.[1637]

Nominal Pump Size	Pressure Air Rang (psig)	Range of Air Consumption (SCFM)	Default Air Consumption (SCFM)
2”	80 – 120 psig (average = 95 psig)	90 – 120	105
3” & 4”	90 – 110 psig (average = 100 psig)	125 - 150	138

kW_{Comp} = System power reduction per air demand (kW/CFM) depending on the type of air compressor found in table below.[1638]

Air Compressor Type	kW_{Comp} (kW/CFM)
Reciprocating – On/off Control	0.184
Reciprocating – Load/Unload	0.136
Screw – Load/Unload	0.152
Screw – Inlet Modulation	0.055
Screw – Inlet Modulation w/ Unloading	0.055
Screw – Variable Displacement	0.153
Screw – VFD	0.178

Or if compressor control type is unknown, then a weighted average based on market share can be used:[1639]

Control Type	Share %	kW / CFM
Market share estimation for load/unload controls compressors	40%	0.136
Market share estimation for modulation w/ unloading control compressors	40%	0.055
Market share estimation for variable displacement control compressors	20%	0.153
Unknown / Weighted average		0.107

Hours = Compressed air system pressurized hours

= Use actual hours if known, otherwise assume values in table below:

[1637] “Demand-Side Savings: Energy Efficiency in Optimizing Compressed Air,” Air Power USA. Page 8-46.
[1638] Calculated based on the type of compressor control. This assumes the compressor will be between 40% and 100% capacity before and after the changes to the system demand. See “Industrial System Standard Deemed Saving Analysis.xls”
[1639] Table 8.2.3, Technical Support Document. US Department of Energy

Shift	Hours
Single Shift	1,976
Two Shifts	3,952
Three Shifts	5,928
Four Shifts or Continual Operation	8,320
Unknown / Weighted average[1640]	5,702

SF = Savings Factor, representing the reduction of compressed air consumed by the pump

= 35%[1641]

For example, a 2-inch AODD is outfitted with a stroke-optimizing control in a Screw – Load/Unload compressor

ΔkWh = 105 * 0.152 * 5,702 * 35%

= 31,851 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh/Hours * CF$$

Where:

ΔkWh = As calculated above

CF = Summer peak coincidence factor

Shift	Coincidence Factor
Single Shift	0.59
Two Shifts	0.95
Three Shifts	0.95
Four Shifts or Continual Operation	0.95
Unknown / Weighted average[1642]	0.89

For example, a 2-inch AODD is outfitted with a stroke-optimizing control in a Screw – Load/Unload compressor

ΔkW = 31,851 / 5,702 * 0.89

= 4.97 kW

4.7.13 Compressed Air Leak Repair

DESCRIPTION

This measure shows the energy savings potential associated with reducing compressed air losses and the repair of compressed air leaks. Compressed air leaks can be responsible for 20-30% of total air compressor output in a facility. This measure is applicable to compressed air systems in manufacturing environments where blow off, pneumatic tools and manufacturing processes of many varieties are used.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is the compressed air system with air leaks identified via a leak survey and leak tags, and then leaks repaired to minimize compressed air wastage.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is an existing compressed air system.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 1 to 5 years.[1643] A range of possible lifetime values is provided as the implementer of this measure must justify the reason for selecting an appropriate measure life for each project and the decision will be subject to evaluation with the risk of adjustment.

DEEMED MEASURE COST

The incremental cost is assumed to be $8 per horsepower[1644]

LOADSHAPE

Loadshape C35 - Industrial Process

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is dependent on the industrial shift and corresponding hours of operation. Values are provided for each shift type in the variable definition section.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (N_{leaks} * CFM_{leaks} * Hours * C_{aircomp} * Control\ factor / hp_{typical}) * hp_{real}$$

Where:

N_{leaks} = Number of leaks repaired

CFM_{leaks} = CFM loss per leak. Estimate based on either ultrasonic leak detection digital decibel readings (preferred) or via visual inspection as provided in the tables below:

[1643] For more detail pertaining to the guidance of the measure life, please see Attachment B: Effective Useful Life for Custom Measure Guidelines

[1644] Engineering estimate from previous project cost data review and engineering judgment as obtained from Minnesota Technical Reference Manual Version 1.2, Industrial Compressed Air – Compressed Air Leak Detection

Ultrasonic Leak Detection[1645]:

Digital Reading	System Air Pressure				
	100 PSIG	75 PSIG	50 PSIG	25 PSIG	10 PSIG
	Estimated CFM_{leaks}				
10 dB	0.5	0.3	0.2	0.1	0.05
20 dB	0.8	0.9	0.5	0.3	0.15

Shift	Hours	Description
Single shift (8/5)	1,976	7 AM – 3 PM, weekdays, minus three-weekday holidays and 10 days of scheduled down time
2-shift (16/5)	3,952	7AM – 11 PM, weekdays, minus three-weekday holidays and 10 days of scheduled down time
3-shift (24/5)	5,928	24 hours per day, weekdays, minus three-weekday holidays and 10 days of scheduled down time
4-shift (24/7)	8,320	24 hours per day, 7 days a week minus three-week day holidays and 10 days of scheduled down time
Unknown / Weighted average	5,702	

Control factor = Efficiency Factors per control type for air compressors from table below. If unknown control type, use 0.3 (%kW/%load)[1648]

Control Type	Control factor (%kW/%load)
Inlet Valve Modulated	0.31
Variable Displacement	0.69
Variable Speed Drive	0.85

$hp_{typical}$ = nominal horsepower of a typical air compressor

= 100 hp[1649]

hp_{real} = total hp of real compressors. This should include the total horsepower of the compressors that normally run through the filter, but not backup compressors

= Actual

For example, a repair of a 500hp system running 3 shifts at 100psig that fixes 10 leaks that are 1/32" in size would save the following:

$\Delta kWh = (N_{leaks} * Hours * CFM_{leaks} * C_{aircomp} * Control\ Factor / hp_{typical}) * hp_{real}$

= (10 * 5,928 * 1.6 * 0.19 * 0.3 / 100) * 500

= 27,032 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (\Delta kWh\ /\ Hours\ ) * CF$$

Where,

CF = Summer peak coincidence factor, see table below

Shift	Coincidence Factor
Single shift (8/5)	0.59
2-shift (16/5)	0.95
3-shift (24/5)	0.95
4-shift (24/7)	0.95

[1648] Compressed Air Challenge "Fundamentals of Compressed Air Systems" Pg 90-91

[1649] Consistent with 4.7.2 Compressed Air Low Pressure Drop Filters. See "Industrial System Standard Deemed Saving Analysis.xls".

Shift	Coincidence Factor
Unknown / Weighted average[1650]	**0.89**

For example, a repair of a 500hp system running 3 shifts at 100psig that fixes 10 leaks that are 1/8" in size would save the following:

ΔkW = (ΔkWh / Hours) * CF

= (27,032 / 5,928) * 0.95

= 4.332 kW

MEASURE CODE: CI-CPA-CALR-V03-260101

REVIEW DEADLINE: 1/1/2029

[1650] Weighting of 16% single shift, 23% two shift, 25% three shift and 36% continual based on DOE evaluation of the Compressed Air Challenge, section 2.1.5 Facility Operating Schedules.

4.8.Shell End Use

4.8.1 Roof Insulation for C&I Facilities

DESCRIPTION

Energy and demand savings are realized through reductions in the building cooling and heating loads by way of improvements in roof assembly thermal resistance properties. This measure was developed to be applicable to the following program types: RF and NC.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is a roof assembly with thermal resistance that exceeds code requirements and should be determined by the program.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition in retrofit scenarios is the thermal resistance of the existing roof assembly.

The baseline for new construction scenarios is the thermal resistance of the roof assembly as mandated by applicable building code. Assembly R-values shall be referenced from IECC 2015 or ASHRAE – 90.1 – 2013, or IECC 2018 or ASHRAE 90.1-2016, or IECC 2021, depending on the IECC in effect on the date of the building permit (if unknown assume IECC 2018).

Note, IECC 2021 became effective statewide on 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure expected useful life (EUL) is assumed to be 20 years per DEER 2008. This is consistent with SDG&E's 9th Year Measure Retrofit Study (1996 & 1997 Residential Weatherization Programs), CPUC's Energy Efficiency Policy Manual v.2, and GDS's Measure Life Report Residential and Commercial/Industrial Lighting and HVAC Measures (June 2007).

DEEMED MEASURE COST

Costs can be highly variable due to differences in building type and structural assemblies and therefore actual costs should be used when possible. Absent of actual cost information, estimated costs can be used. Per the W017 Itron California Measure Cost Study,[1651] the material cost for R-30 insulation is $0.59 per square foot. The installation cost is $0.81 per square foot. The total measure cost, therefore, is $1.40 per square foot of insulation installed.

LOADSHAPE

Loadshape C03: Commercial Cooling

Loadshape C04 - Commercial Electric Heating

Loadshape C05 - Commercial Electric Heating and Cooling

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

[1651] Measure costs are from the "2010-2012 WO017 Ex Ante Measure Cost Study", Itron, California Public Utilities Commission, May 2014. The data is provided in a file named "MCS Results Matrix – Volume I".

= 91.3% [1652]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1653]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Electric energy savings is calculated as the sum of energy saved when cooling the building and energy saved when heating the building

$$\Delta kWh = \Delta kWh_cooling + \Delta kWh_heating$$

If central cooling, the electric energy saved in annual cooling due to the added insulation is

$$\Delta kWh_cooling = ((1/R_existing) - (1/R_new)) * Area * EFLH_{cooling} * \Delta T_{FL,cooling} / 1{,}000 / \eta_cooling$$

Where:

R_existing = Roof assembly heat loss coefficient with existing (or code required) insulation [(hr-^{o}F-ft^{2})/Btu]

= In retrofit scenarios, actual existing conditions prior to retrofit should be used. If unavailable, default values by building type can be used, as outlined in the following table and adopted from Ohio Energy Technical Reference Manual and expanded to cover all type of commercial buildings in the state of Illinois. In new construction scenarios, the applicable code requirements, per the following tables, should be used.

For retrofits, the R-value for the entire assembly:

Building Type	Retrofit Assembly R-Value
Assembly	13.5
Assisted Living	13.5
College	13.5
Convenience Store	13.5
Elementary School	13.5
Garage	13.5
Grocery	13.5
Healthcare Clinic	13.5
High School	13.5
Hospital	13.5
Hotel/Motel	13.5
Manufacturing Facility	12.0
MF - High Rise	13.5
MF - Mid Rise	13.5
Movie Theater	13.5
Office - High Rise	13.5

[1652] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1653] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Building Type	Retrofit Assembly R-Value
Office - Low Rise	13.5
Office - Mid Rise	13.5
Religious Building	13.5
Restaurant	13.5
Retail - Department Store	13.5
Retail - Strip Mall	13.5
Warehouse	12.0
Unknown	13.5

R-Values: ASHRAE – 90.1 – 2013 and 2016

	IL TRM Zones 1, 2, & 3 [ASHRAE/IECC Climate Zone 5 (A, B, C)]			
	Nonresidential		Semiheated	
	Assembly Maximum	Insulation Min. R-Value	Assembly Maximum	Insulation Min. R-Value
Insulation Entirely Above Deck	0.032	R-30.0 c.i.	0.063	R-15 c.i.
Metal Building (Roof)	0.037	R-19 + R-11 Ls or R-25 + R-8 Ls	0.082	R-19

Attic and Other	0.021	R-49	0.034	R-30

Table Notes

c.i. = continuous insulation

Ls = linear system, a continuous vapor barrier liner installed below the purlins and uninterrupted by framing members

R_new = Roof assembly heat loss coefficienty with new insulation [(hr-^oF-ft^2)/Btu]

Area = Area of the roof surface in square feet.

$EFLH_{cooling}$ = Equivalent Full Load Hours for Cooling [hr] in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

$\Delta T_{FL,cooling}$ = Temperature difference [^oF] during cooling season between design day outdoor air temperature (T_{DD}) and assumed 55^oF base temperature

Climate Zone (City based upon)	$T_{DD,,cooling}$ [°F][1654]	$\Delta T_{FL,cooling}$ [°F]
1 (Rockford)	90.9	35.9
2 (Chicago)	91.3	36.3
3 (Springfield)	92.6	37.6
4 (Belleville)	95.2	40.2
5 (Marion)	94.4	39.4

1,000 = Conversion from Btu to kBtu

η_cooling = Efficiency of cooling equipment * Distribution Efficiency. Actual, if known and assume 95% distribution efficiency for central cooling with ducts. If unknown, assume 11.1 SEER2.[1655]

If the building is heated with electric heat (resistance or heat pump), the electric energy saved in annual heating due to the added insulation is

$$\Delta kWh_heating = [(1/R_existing) - (1/R_new)] * Area * EFLH_{heating} * \Delta T_{FL,heating} / 3{,}412 / \eta_heating$$

Where:

$EFLH_{heating}$ = Equivalent Full Load Hours for Heating [hr] in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

$\Delta T_{FL,heating}$ = Temperature difference [°F] during heating season between design day outdoor air temperature and assumed 55°F heating base temperature

Climate Zone (City based upon)	$T_{DD,heating}$ [°F][1656]	$\Delta T_{FL,heating}$ [°F]
1 (Rockford)	-5.4	60.4
2 (Chicago)	-1.0	56.0
3 (Springfield)	1.1	53.9
4 (Belleville)	7.2	47.8
5 (Marion)	10.1	44.9

3,142 = Conversion from Btu to kWh.

η_heating = Efficiency of heating system. Use actual efficiency. If not available refer to default table below.

[1654] Weather Station Data, 0.4% Cooling DB - 2021 ASHRAE Handbook, Fundamentals. The following weather stations were referenced: Climate Zone 1: Chicago Rockford Int'l, Climate Zone 2: Chicago O'Hare Int'l, Climate Zone 3: Abraham Lincoln Capital, Climate Zone 4: Scott AFB, Climate Zone 5: Cape Girardeau Regional.

[1655] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER value converted to SEER2 by multiplying by 0.95, multiplied by 0.95 distribution efficiency.

[1656] Weather Station Data, 96.6% Heating DB - 2021 ASHRAE Handbook, Fundamentals. The following weather stations were referenced: Climate Zone 1: Chicago Rockford Int'l, Climate Zone 2: Chicago O'Hare Int'l, Climate Zone 3: Abraham Lincoln Capital, Climate Zone 4: Scott AFB, Climate Zone 5: Cape Girardeau Regional.

System Type	HSPF2 Estimate	ηHeat (Effective COP Estimate) (HSPF2/3.413)*0.95 (Distribution efficiency)
Heat Pump	7.37[1657]	2.05
Resistance	N/A	1

If the building is heated with a gas furnace, there will be some electric savings in heating the building attributed to extra insulation since the furnace fans will run less.

$$\Delta kWh_heating = \Delta Therms * Fe * 29.3$$

Where:

ΔTherms = Gas savings calculated with equation below.

Fe = Percentage of heating energy consumed by fans, assume 7.7%[1658]

29.3 = Conversion from therms to kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (\Delta kWh_cooling / EFLH_cooling) * CF$$

Where:

$EFLH_{cooling}$ = Equivalent full load hours of air conditioning in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1659]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1660]

FOSSIL FUEL SAVINGS

If building uses a gas furnace, the savings resulting from the insulation is calculated using the following formula.

$$\Delta Therms = ((1/R_existing) - (1/R_new)) * Area * EFLH_{heating} * \Delta T_{FL,heating} / 100{,}000 / \eta_heat$$

Where:

R_existing = Roof assembly heat loss coefficient with existing (or code required) insulation [(hr-^{o}F-ft^2)/Btu], per guidance outlined in Electric Energy Savings section.

R_new = Roof assembly heat loss coefficient with new insulation [(hr-^{o}F-ft^2)/Btu]

[1657] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note HSPF value converted to HSPF2 by multiplying by 0.85.

[1658] F_e is estimated using TRM models for the three most popular building types for programmable thermostats: low-rise office (10.2%), sit-down restaurant (8.6%), and retail – strip mall (4.4%). 7.7% reflects the average Fe of the three building types. See "Fan Energy Factor Example Calculation 2021-06-23.xlsx" for reference.

[1659] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1660] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Area	= Area of the roof surface in square feet. Assume 1000 sq ft for planning.
$EFLH_{heating}$	= Equivalent Full Load Hours for Heating in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use
$\Delta T_{FL,heating}$	= Temperature difference [^{o}F] during heating season between design day outdoor air temperature and assumed 55^{o}F heating base temperature (see above)
100,000	= Conversion from BTUs to Therms
η_heat	= Efficiency of existing furnace. Assume 0.82 for planning purposes[1661].

MEASURE CODE: CI-SHL-RINS-V10-260101

REVIEW DEADLINE: 1/1/2029

[1661] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Value based on weighting AFUE and Thermal Efficiency, and incorporating estimate of distribution losses of 0.95.

4.8.2 Spring-Loaded Garage Door Hinge

DESCRIPTION

Existing overhead doors often close loosely at the perimeter weather strips and between panels. Conditioned air escapes through these gaps, leading to energy loss. Spring-loaded hinges create tension and reduce gaps at the perimeter and between panels. The product is applicable for small-commercial and residential sectors, but the savings estimated by this measure apply only to small-commercial applications. This measure applies to sites where the inside area of the garage is conditioned during the heating season by natural gas.

This measure was developed to be applicable to the following program types: NC, RF. If applied to other program types, the measure savings should be verified as a custom measure.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment consists of a heavy-duty spring-loaded hinge installed in place of a standard hinge on a garage overhead door. The number of hinges per project may vary depending on the door type, size, and number of panels. The efficient condition is an air sealed garage door with no gaps around the perimeter or between panels.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a garage door with a 1/8-inch gap between the door and the weather-stripping around the perimeter of the door. The bottom of the door is assumed sealed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years.[1662]

DEEMED MEASURE COST

Incremental costs equal installed cost and will vary based on the number of hinges required per door. Based on information provided by the manufacturer to Nicor Gas, average material cost is $126 per garage door and installation cost is $63 per garage door for a total installed cost of $189 per garage door. The typical garage door is assumed to have 4 panels and 9 total hinges.

LOADSHAPE

Loadshape C04 - Commercial Electric Heating

COINCIDENCE FACTOR

Savings relate to heating only so coincidence factor is assumed to be 0.

Algorithm

CALCULATION OF ENERGY SAVINGS

Savings are calculated based on a reduction in airflow rate associated with decreased infiltration across the leakage area. The algorithm below for change in cubic feet per minute, ΔCFM, is modeled after equation 48 in Chapter 16: Ventilation and infiltration of the 2017 ASHRAE Handbook—Fundamentals.

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS

$$\Delta kWh = \Delta HeatLoad / COP_{heat} / Conv_{kWh} * EFLH_H$$

$$\Delta Therms = \Delta HeatLoad / Eff_{heat} / Conv_{BTU} * EFLH_H$$

[1662] Public Service Commission of Wisconsin, "Evaluation – Business Program: Measure Life Study," Focus on Energy (2009): page 1-4, Table 1-2 Recommended Measure Life by WISeerts Group Description for Building Shell Equip or Tech measure type, accessed March 26, 2019, https://focusonenergy.com/sites/default/files/bpmeasurelifestudyfinal_evaluationreport.pdf.

$$\Delta HeatLoad = \Delta CFM * Conv_{min} * Density_{air} * SpecificHeat_{air} * \Delta T$$

$$\Delta CFM = A_l * [(C_s * \Delta T) + (C_w * W_s^2)]^{0.5}$$

Where:

A_l = Leakage area, estimated at 51 (in^2), of air gap before retrofit.[1663]

C_s = Stack coefficient, 0.0299 ($cfm^2/in^4 * °F$), adjustment based on airflow at average building height.[1664]

C_w = Wind coefficient, 0.0086 ($cfm^2/in^4 * mph^2$), adjustment based on airflow at average building height and wind shelter classification.[1665]

ΔT = Average temperature difference between outside air temperature (OAT) during the heating season[1666] and assumed indoor heating temperature setpoint 70°F;[1667] see table below.

W_s = Average wind speed (mph) during heating season, see table below.

Climate Zone	Average OAT, Heating (°F)	Average Delta T, Heating (°F)	Average heating Season Wind Speed (mph) [1668]
1 (Rockford)	32	38	10
2 (Chicago)	34	36	10
3 (Springfield)	35	35	10
4 (Belleville)	36	34	9
5 (Marion)	39	31	7

$Conv_{min}$ = Conversion from minutes to hours, 60 minutes/hour.

$Density_{air}$ = The density of air, 0.08 (lb/ft^3) at 1 atmosphere pressure and approximately 30-40°F.[1669]

$SpecificHeat_{air}$ = Specific heat of air, 0.24 (BTU/lb) at 1 atmosphere pressure and 32°F.[1670]

COP_{heat} = COP of electric heating system

[1663] Leakage area is estimated based on average door size of installations previously completed in Wisconsin and reported in the Wisconsin Focus on Energy Technical Reference Manual. Average door size is 10 ft x 12 ft, with a side and top perimeter equal to 1 top * (10 ft * 12 in/1 ft) + 2 sides* (12 ft * 12 in/1ft) = 408 in. At 1/8 in perimeter gap, the leakage area is 408 in * 1/8 in = 51 in^2.

[1664] 2017 ASHRAE Handbook—Fundamentals, 16.24, Table 4 "Basic Model Stack Coefficient C_s", assumed average building height of 16 feet, two-story.

[1665] 2017 ASHRAE Handbook—Fundamentals, 16.24, Table 6 "Basic Model Wind Coefficient C_w", assumed average building height of 16 feet and shelter class 3: "Typical shelter caused by other buildings across street from building under study."

[1666] DOE Weather Data, TMY3 (Typical Meteorological Year), developed by NREL, for the average outdoor temperature when the heating system is expected to be operating.

[1667] Energy Center of Wisconsin, "Baseline Building Energy Models – Nonresidential Heating Thermostat Setpoint," ComEd Portfolio Modeling Report (July 2010): page 6.

[1668] DOE Weather Data, TMY3 (Typical Meteorological Year), developed by NREL, for the average wind speed when the heating system is expected to be operating, defined as hours where the average temperature is lower than 55°F.

[1670] Engineering ToolBox, (2004). Air - Specific Heat at Constant Pressure and Varying Temperature. [online] Available at: https://www.engineeringtoolbox.com/air-specific-heat-capacity-d_705.html [Accessed March 2019].

= If heat pump, assume 2.5 for New Construction and 2.05 for existing buildings[1671]

= 1.0 if electric resistance heating

Eff_{heat} = Efficiency of the heating system, assume 0.82 for planning purposes. [1672]

$Conv_{\text{kWh}}$ = Conversion from BTUs to kWh

= 3,412 BTU/kWh

$Conv_{Therms}$ = Conversion from BTUs to therms

$=$ 100,000 BTU/therm.

$EFLH_H$ =Equivalent Full Load Heating Hours in Existing Buildings or New Construction are listed in section 4.4 HVAC End Use.

Savings for all climate zones and selected building types are presented in the following tables:

4.8.3 Commercial Weather Stripping

DESCRIPTION

Note- this measure provides a prescriptive approach for commercial door sweeps. A more comprehensive approach that requires a number of additional inputs for both this and a number of other commercial air sealing opportunities is provided in measure 4.8.27 C&I Air Sealing.

Entrance/exit doors installed for a commercial or industrial buildings often leave clearance gaps to allow for proper operation. The gaps around the doors allow unconditioned air to infiltrate the building due to wind force, internal building stack affect, and other temperature differentials, thus adding to the cooling and heating loads of an HVAC system. Sweeps and other weatherstripping applications are designed to close these gaps, while still allowing proper operation. They are installed along the bottom, head, and jambs of exterior doors to prevent air infiltration from adding to the HVAC load.

This measure was developed to be applicable to the following program types: RF, DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

There are a variety of types of materials used as door sweeps and weather stripping, including nylon bristles, felt, vinyl, open or closed-cell foam, and EPDM rubber. Their effectiveness is assumed to be the same when properly installed.

DEFINITION OF BASELINE EQUIPMENT

This measure shall apply to the exterior doors on commercial buildings that are not sealed from the outside environment (i.e., interior vestibule doors would be ineligible) with visible gaps of at least 1/8 inches and up to 3/4 inches along any outside edge of the door. The space on the interior of the door must be conditioned and/or heated, and the calculation methodology will use standard efficiencies of 1.0 kW/ton for cooling and 80% for heating. Electric resistance heating and electric heat pump systems will use coefficients of performance (COPs) of 1.0 and 3.3, respectively.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated useful life (EUL) is 10 years.[1673]

DEEMED MEASURE COST

Costs for this measure should be determined by actual quotes obtained from manufacturers and estimated labor. If not available, it is estimated based on brush weather strips cost of $5.50/LF with labor and other direct costs of installation costing $2.50/LF with the total coming to $8.00/LF.[1674]

LOADSHAPE

Loadshape C03 - Commercial Cooling

Loadshape C04 - Commercial Electric Heating

Loadshape C05 - Commercial Electric Heating and Cooling

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1675]

[1673] Assumed lower than residential due to likely significantly higher door usage.

[1674] Deemed costs referenced from the Arkansas TRM.

[1675] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)
= 47.8% [1676]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (\Delta kWhCool_{weatherstrip} + \Delta kWhHeat_{weatherstrip}) * Length$$

Where:

$\Delta kWhCool_{weatherstrip}$ = Annual cooling kWh savings from installation of door sweep per linear foot [1677]

Climate Zone (City based upon)	$\Delta kWhCool_{weatherstrip}$ per linear ft
1 (Rockford)	0.33
2 (Chicago)	0.36
3 (Springfield)	0.63
4 (Belleville)	0.59
5 (Marion)	0.70

$\Delta kWhHeat_{weatherstrip}$ = Annual heating kWh savings from installation of door sweep per linear foot [1678]

Climate Zone (City based upon)	$\Delta kWh_{weatherstrip}$ per linear ft	
	Electric Resistance	Heat Pump
1 (Rockford)	89.4	44.7
2 (Chicago)	78.6	39.3
3 (Springfield)	69.2	34.6
4 (Belleville)	59.9	29.9
5 (Marion)	48.0	24.0

Length = Linear feet of door weatherstripping installed

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (\Delta kWhCool_{weatherstrip} * Length) / EFLH_{cooling} * CF$$

Where:

[1676] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1677] Savings are based on lab test results performed by CLEAResult, assuming an 1/8"gap. See 'Commercial Weather Stripping IL_TRM_Workpaper v1.2'. Following discussion with the TAC it was determined that due to concerns over engineering algorithms overclaiming savings, 50% of the savings for the 1/8"gap are deemed appropriate.
[1678] Converts the Therm value to kWh and incorporates the relative COP efficiencies (assumed 0.78 for gas heat, 1 for electric resistance and 2.0 for heat pumps).

$EFLH_{cooling}$ = Equivalent full load hours of air conditioning in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1679]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1680]

FOSSIL FUEL SAVINGS

ΔTherms = $\Delta Therms_{weatherstrip} * Length$

Where:

$\Delta Therms_{weatherstrip}$ = Annual therm savings from installation of door sweep per linear foot[1681]

Climate Zone (City based upon)	$\Delta Therms_{weatherstrip}$ per linear ft
1 (Rockford)	3.91
2 (Chicago)	3.44
3 (Springfield)	3.03
4 (Belleville)	2.62
5 (Marion)	2.1

Length = Linear feet of door weatherstripping installed

[1679] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1680] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1681] Savings are based on lab test results performed by CLEAResult, assuming an 1/8"gap. See 'Commercial Weather Stripping IL_TRM_Workpaper v1.2'. Following discussion with the TAC it was determined that due to concerns over engineering algorithms overclaiming savings, 50% of the savings for 1/8"gap are deemed appropriate. This provides a savings assumption that is similar to the prescriptive Residential door sweep measure in 5.6.1 Air Sealing (assuming 3 ft doorsweep).

4.8.4 C&I Air Sealing

DESCRIPTION

Note- this measure provides a comprehensive approach for various commercial air sealing opportunities. A prescriptive approach for door sweeps only is provided in measure 4.8.16 C&I Weather Stripping.

This Air Sealing Measure incorporates a wide variety of products and procedures that reduce unwanted uncontrolled outdoor air infiltration into commercial or industrial buildings. Unwanted outdoor air causes significant increases in both heating and cooling costs throughout most of the year, and causes unwanted introduction of dust and odors into the building. This outdoor air infiltration is caused by both wind blowing against one or more sides of the building, and also through thermal stack effects in tall buildings that cause infiltration on lower floors and exfiltration on upper floors.

This measure applies to all existing commercial and industrial buildings that utilize mechanical heating and/or cooling to maintain occupant comfort. Identifying the exact length and width of cracks and holes in a building is difficult to do accurately. Similarly, conducting a building pressurization test using multiple blower doors or programming the air handling equipment to pressurize a building is also impractical in most situations. Therefore, this measure's savings calculations are instead based primarily on deemed values of air leakage reduction per unit length or unit area of air sealing retrofits installed.[1682] If a blower door or air handler pressurization and measurement test can be done both before and after air sealing, the amount of air cfm reduction, adjusted to 50 pascals of pressure differential, may be directly inserted into the 'Annual Avg infiltration CFM Saved' value to determine annual energy savings.

This measure was developed to be applicable to the following program types: RF

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Air sealing materials and diagnostic testing should meet all eligibility program qualification criteria. If applicable, the initial and final tested leakage rates should be performed in such a manner that the identified reductions can be properly discerned, particularly in situations wherein multiple building envelope measures may be implemented simultaneously.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition of a building upon first inspection significantly impacts the opportunity for cost-effective energy savings through air-sealing.

If applicable and feasible, the existing air leakage rate for an existing building may be determined through approved and appropriate test methods using either blower doors or air handling units programmed to pressurize the building. Outdoor air flow quantities and simultaneous measurements of building differential pressure (inside vs outside) must be measured using approved methods and adjusted to values at 50 pascals differential.

Alternatively, if actual leakage rates cannot be measured, air leakage savings may be deemed using quantities of air leakage lengths or quantities based on inspection of the building. Lengths of cracks to be filled, quantities of leaky doors or windows to be sealed, etc. are documented and prescriptive, deemed savings rates are used to estimate savings.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years.[1683]

[1682] ASHRAE, 2001 AHSRAE Handbook – Fundamentals, Chapter 26, Table 1. Effective Air Leakage Areas (Low-Rise Residential Applications Only).

[1683] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.

MEASURE COST

Use actual cost of air sealing measures installed, if available. If actual costs are unknown, use estimated costs from table below multiplied by the number of units of each application installed:

Technology	Application	Unit Definition	Unit Cost Estimate[1684]
Weather Stripping	Single Door - Weather Stripping, Sweep	Enter Number of Doors Retrofitted	$37
	Double Doors - Weather Stripping	Enter Number of Double Door Sets Retrofitted	$166
	Casement Window - Weather Stripping	Enter Lin. Ft. of Crack Retrofitted	$5
	Double Horizontal Slider, Wood - Weather Stripping	Enter Lin. Ft. of Crack Retrofitted	$5
	Double-Hung - Weather Stripping	Enter Lin. Ft. of Crack Retrofitted	$5
	Double-Hung, with Storm Window - Weather Stripping	Enter Lin. Ft. of Crack Retrofitted	$5
	Roof-Wall Intersection, Block Seal	Enter Lin. Ft. of Crack Retrofitted	$10
	Roof-Wall Intersection, Seal Paint	Enter Lin. Ft. of Crack Retrofitted	$23
	Roof-Wall Intersection, Seal	Enter Lin. Ft. of Crack Retrofitted	$6
	Piping/Plumbing/Wiring Penetrations - Sealing	Enter Number of Penetrations Retrofitted	$50
Caulking	Caulking, External Block	Enter Lin. Ft. of Crack Retrofitted	$12
	Caulking, Internal Seal	Enter Lin. Ft. of Crack Retrofitted	$6
Attic Sealing	Attic Bypass Air Sealing, Block, Seal	Each	$386
	Attic Bypass Air Sealing, Seal	Each	$249
	Retrofit Existing Attic Hatch	Each	$223
Gasket	Exterior Wall Outlet Penetrations - Gasket	Enter Number of Outlets Retrofitted	$5
Avg Caulking / Weather Stripping	Average Window/Door Caulking / Weather Stripping	Enter Lin. Ft. of Crack Retrofitted	$10

LOADSHAPE

Loadshape C01 – Commercial Electric Cooling

Loadshape C03 – Commercial Cooling

Loadshape C04 – Commercial Electric Heating

Loadshape C05 – Commercial Electric Heating and Cooling

Loadshape C23 – Commercial Ventilation

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's

[1684] Typical project costs from quotation for large commercial air sealing project in Northeast (site: Concord, NH). All unit prices taken from BE Retrofit quote, October 2021.

capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1685]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1686]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

ΔkWh = $\Delta kWh_cooling + \Delta kWh_heatingElectric + \Delta kWh_heatingFurnace$

ΔkWh_cooling = If building is cooled, reduction in annual cooling requirement due to air sealing

= $1.08 * Infiltration_CFM_Saved * EFLH_{cooling} * \Delta T_{FL,cooling} / 1000 / \eta Cool * \%Cool$

ΔkWh_heatingElectric = if building is electrically heated, reduction in annual heating requirement due to air sealing

= $1.08 * Infiltration_CFM_Saved * EFLH_{heating} * \Delta T_{FL,heating} / \eta Heat / 3{,}412 * \%ElectricHeat$

ΔkWh_heatingGas = If gas furnace or gas boiler heat, kWh savings for reduction in combustion fan run time

= $\Delta Therms * Fe * 29.3$

Where:

1.08 = Specific heat of air x density of inlet air @ 70F x 60 min/hr in BTU/hr-F-CFM

Infiltration_CFM_Saved = Annual average CFM of outdoor air infiltration reduced due to air sealing measures implemented

= Calculated EITHER by sum of applicable values from table below multiplied by the quantities of each item implemented[1687]

Technology	Application	Delta CFM50 per Unit	Unit Definition
Weather Stripping	Single Door - Weather Stripping	25.500	Enter Number of Doors Retrofitted
	Double Doors - Weather Stripping	0.730	Enter Sq. Ft. of Both Doors Retrofitted
	Casement Window - Weather Stripping	0.360	Enter Lin. Ft. of Crack Retrofitted
	Double Horizontal Slider, Wood - Weather Stripping	0.473	Enter Lin. Ft. of Crack Retrofitted

[1685] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[1686] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1687] ASHRAE, 2001 AHSRAE Handbook – Fundamentals, Chapter 26, Table 1. Effective Air Leakage Areas (Low-Rise Residential Applications Only).

Technology	Application	Delta CFM50 per Unit	Unit Definition
	Double-Hung - Weather Stripping	1.618	Enter Lin. Ft. of Crack Retrofitted
	Double-Hung, with Storm Window - Weather Stripping	0.164	Enter Lin. Ft. of Crack Retrofitted
	Average Caulking Weatherstripping	0.639	Enter Lin. Ft. of Crack Retrofitted
	Piping/Plumbing/Wiring Penetrations - Sealing	10.900	Enter Number of Penetrations Retrofitted
Caulking	Window Framing, Masonry - Caulking	1.364	Enter Sq. Ft. of Windows Retrofitted
	Window Framing, Wood - Caulking	0.382	Enter Sq. Ft. of Windows Retrofitted

	Door Frame, Wood - Caulking	0.364	Enter Sq. Ft. of Doors Retrofitted
	Average Window/Door - Caulking	0.689	Enter Lin. Ft. of Crack Retrofitted
Avg Caulking / Weather Stripping	Average Window/Door Caulking / Weather Stripping	0.664	Enter Lin. Ft. of Crack Retrofitted
Gasket	Electrical Outlets - Gasket	6.491	Enter Number of Outlets Retrofitted

OR if blower door or total building pressurization measurements have been conducted, by determining the CFM infiltration differential between the existing and efficient building air infiltration rates:

= CFM50_existing - CFM50_efficient

Where:

CFM50_existing = CFM of Infiltration measured by blower door or by total building pressurization test before air sealing, adjusting measured CFM to equivalent CFM at 50 pascals indoor/outdoor pressure differential[1688]

CFM50_efficient = Infiltration as measured by blower door or total building pressurization text after air sealing, adjusted to equivalent CFM at 50 pascals pressure differential

$EFLH_{cooling}$ = Equivalent Full Load Hours for Cooling [hr] in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

$\Delta T_{FL,cooling}$ = Temperature difference [^{o}F] during cooling season between design day outdoor air temperature (T_{DD}) and assumed 55^{o}F base temperature

Climate Zone (City based upon)	$T_{DD,,cooling}$ [°F][1689]	$\Delta T_{FL,cooling}$ [°F]
1 (Rockford)	90.9	35.9
2 (Chicago)	91.3	36.3
3 (Springfield)	92.6	37.6
4 (Belleville)	95.2	40.2
5 (Marion)	94.4	39.4

[1688] 50 Pascals has been established in TRM XXX as the standard building pressure differential for determining average annual infiltration rates; 50 Pascals differential is equivalent to a wind pressure from approximately 10 mph.

[1689] Weather Station Data, 0.4% Cooling DB - 2021 ASHRAE Handbook, Fundamentals. The following weather stations were referenced: Climate Zone 1: Chicago Rockford Int'l, Climate Zone 2: Chicago O'Hare Int'l, Climate Zone 3: Abraham Lincoln Capital, Climate Zone 4: Scott AFB, Climate Zone 5: Cape Girardeau Regional.

1000 = Conversion of watts to kW

ηCool = Efficiency of cooling equipment * distribution efficiency. Actual and assume 95% distribution efficiency for central cooling with ducts. If unknown assume:[1690]

Space Cooling Source	Deemed Cooling EER2	Deemed Cooling SEER2
No Cooling	N/A	N/A
Unknown Cooling Source	10.2	11.1

%Cool = Percentage of the building that is cooled

$EFLH_{heating}$ = Equivalent Full Load Hours for Heating [hr] in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

$\Delta T_{FL,heating}$ = Temperature difference [^{o}F] during heating season between design day outdoor air temperature and assumed 55^{o}F heating base temperature

Climate Zone (City based upon)	$T_{DD,heating}$ [°F][1691]	$\Delta T_{FL,heating}$ [°F]
1 (Rockford)	-5.4	60.4
2 (Chicago)	-1.0	56.0
3 (Springfield)	1.1	53.9
4 (Belleville)	7.2	47.8
5 (Marion)	10.1	44.9

ηHeat = Efficiency of heating equipment * distribution efficiency. Actual, if possible and assume 95% distribution efficiency. Alternatively, as deemed from table below:

System Type	HSPF2 Estimate	ηHeat (Effective COP Estimate) (HSPF2/3.413)*0.95 (Distribution Efficiency)
Heat Pump	7.37[1692]	2.05
Resistance	N/A	1

3,412 = Number of BTUs per kWh

%ElectricHeat = % of building heated by electricity

Fe = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 7.7%[1693]

29.3 = kWh per therm (= 100,000 BTU/Therm / 3,412 BTU/kWh)

[1690] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER and EER values converted to SEER2/EER2 by multiplying by 0.95 and multiplied by 0.95 distribution efficiency.

[1691] Weather Station Data, 96.6% Heating DB - 2021 ASHRAE Handbook, Fundamentals. The following weather stations were referenced: Climate Zone 1: Chicago Rockford Int'l, Climate Zone 2: Chicago O'Hare Int'l, Climate Zone 3: Abraham Lincoln Capital, Climate Zone 4: Scott AFB, Climate Zone 5: Cape Girardeau Regional.

[1692] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note HSPF value converted to HSPF2 by multiplying by 0.85.

[1693] F_e is estimated using TRM models for the three most popular building types for programmable thermostats: low-rise office (10.2%), sit-down restaurant (8.6%), and retail – strip mall (4.4%). 7.7% reflects the average Fe of the three building types. See "Fan Energy Factor Example Calculation 2021-06-23.xlsx" for reference.

For example, assuming air conditioned and electric resistance heated mid rise office building with 10 IEER equipment in Rockford: Infiltration_CFM_Saved = 272.8; ηCool = 10.0; %Cool = 100%, ηHeat = 1.0; %ElectricHeat = 100%, then

ΔkWh_Cooling = 1.08 * 272.8 * 1128 * 35.9 / 1000 / 10 * 100%

= 1,193 kWh of cooling energy saved

ΔkWh_Heating = 1.08 * 272.8 * 1,672 * 60.4 / 1.0 / 3,412 * 100%

= 8,720 kWh of cooling energy saved

ΔkWh = ΔkWh_cooling + ΔkWh_heatingElectric + ΔkWh_heatingFurnace

= 1,193 + 8,720 + 0

= 9,913 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh_cooling \; / \; EFLH_{cooling} \; * \; CF$$

Where:

ΔkWh_cooling = Sum of kWh saved from cooling from above calculations

$EFLH_{cooling}$ = Equivalent Full Load Hours for cooling in Existing Buildings are provided in section 4.4 HVAC End Use

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1694]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1695]

For example, for an mid rise office in Rockford with air conditioning as defined earlier in this section; assuming: = ΔkWh_cooling = 1200; EFLH = 834; CF_{SSP} = 0.913, then

ΔkW = 1193 / 1135 * 0.913

= 0.96 kW

FOSSIL FUEL SAVINGS

If Fossil Fuel heating:

$\Delta Therms = 1.08 * Infiltration_CFM_Saved * EFLH_{heating} * \Delta T_{FL,heating} / \eta Heat / 100{,}000 * \%FossilHeat$

Where:

[1694] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1695] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

ηHeat	= Actual, if unknown assume 0.821.[1696]
100,000	= BTUs per therm
%FossilHeat	= % of building heated by fossil fuel

For Example, assuming for a mid rise office in Rockford with unknown natural gas heat: Infiltration_CFM_Saved =272.8; HDD55/yr = 2284; ηHeat = 0.80; %GasHeat = 100%, then

Δ Therms = 1.08 * 272.8 * 1672 * 60.4 / 0.80 / 100000 * 100%

= 372 Therms

MEASURE CODE: CI-SHL-CAIR-V05-260101

REVIEW DEADLINE: 1/1/2026

1696 Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

4.8.5 High Speed Overhead Doors

DESCRIPTION

This measure applies to buildings with exterior entryways that utilize overhead doors between heated and/or air conditioned spaces and the outdoors that see a high amount of traffic on a daily basis. High speed doors for refrigerated spaces are covered in section 4.6.10 of the TRM. All other high speed door applications, such as conventional foot-traffic entryways, require custom analysis.

The use of overhead doors within exterior entryways during the heating season leads to the exfiltration of warm air from the upper portion of the door opening and the infiltration of colder air from the lower portion of the door opening. This results in increased heating energy use to compensate for heat losses every time a door is opened. By reducing the time it takes for the door to open and close, high speed doors can also enhance the physical comfort of employees or customers near the entryway as there will be reduced temperature fluctuations when the door is opened and closed. In addition, in some cases excess heating capacity may be installed in buildings to meet this larger heating load. The addition of high speed doors to exterior entryways that currently utilize standard overhead doors will result in energy savings and enhanced personal comfort, and also possibly in reduced equipment sizing and associated costs.

The primary markets for this measure are commercial and industrial facilities with overhead doors in exterior entryways, including but not limited to the following building types: manufacturing, warehouse (non-refrigerated), vehicle maintenance facilities, and enclosed/heated commercial or multifamily parking garages.

This measure was developed to be applicable to the following program types: NC, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a High Speed Door installed at a loading dock or drive-in door for a heated and/or cooled warehouse, manufacturing, service garage, or similar space. Heating can be gas fired or electric heat pump. Doors which have a refrigerated space on the interior should use measure 4.6.10 for High Speed Rollup Doors. Doors separating interior spaces with different temperature setpoints on either side are not eligible.

High speed doors must have a minimum opening speed of 32 inches per second and a minimum closing speed of 24 inches per second[1697].

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a standard overhead door, which is generally estimated to have an opening and closing speed of around 8 inches per second[1698]. The doorway should not have any type of existing open-doorway protection such as strip curtains or air curtains.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 16 years.[1699]

DEEMED MEASURE COST

The incremental measure cost is $105/sqft.[1700]

[1697] DASMA Standard 403-2020, "Specification for High Speed Doors and Grilles", DASMA Standard (2020): Section 2.6.

[1698] Wendt, Jeff, "When a High-Speed Door is More Energy Efficient", Door & Access Systems Magazine – Tech Tips. September 2014.

[1699] Assumed same measure life as high speed rollup doors for refrigerated spaces (4.6.10); As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.

[1700] The incremental cost is derived from analysis of a set of PG NSG custom project data, and based on equipment quotes in 2021.

LOADSHAPE

Heating Season: If electric heating, use Commercial Electric Heating Loadshape: C04. Otherwise, N/A

Cooling Season: Commercial Cooling Loadshape C03. Or, if applicable, use Commercial Electric Heating and Cooling Loadshape C05.

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%[1701]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1702]

Algorithm

CALCULATION OF ENERGY SAVINGS

The following formulas provide a methodology for estimating cooling load (kWh) and heating load (therm) savings associated with the installation of a high speed overhead door on exterior entryways such as a single door or loading bay. This algorithm is based on the assumption that savings are directly related to the difference in cooling or heating losses due to infiltration or exfiltration through an entryway before and after the installation of the high speed door. Energy savings are assumed to be the result of a reduction of natural infiltration effects due to wind and thermal forces and follow the calculation methodology outlined by the ASHRAE Handbook.[1703]

This algorithm allows either actual inputs or provides estimates if actual data is not available. All weather dependent values are derived from TMY3 data for the closest weather station to those locations defined elsewhere in the Illinois TRM (which are based on 30 year climate normals). If TMY3 weather station data was not available for the data used in the Illinois TRM, the next closest weather station was used. It is assumed that weather variations are negligible between the weather stations located within the same region. This approach was followed as the high speed door algorithm has a number of weather dependent variables, which are all calculated in relation to the heating season or cooling season as defined by the balance point temperature deemed appropriate for the facility. All weather dependent data is based on TMY3 data and is listed in tables by both climate zone and balance point temperature, which is then normalized to the Illinois TRM climate zoned HDD/CDD definitions unless otherwise noted.

ELECTRIC ENERGY SAVINGS

$\Delta kWh_{cooling} = (Q \,/\, EER2) * (t_{standard} - t_{fast}) * CD$

$\Delta kWh_{HPheating} = (Q \,/\, HSPF2) * (t_{standard} - t_{fast}) * HD$

Where:

Q = rate of total heat transfer through the open entryway (kBtu/hr)

(see calculation in 'Heat Transfer Through Open Entryway' section below)

EER2 = energy efficiency ratio of the cooling equipment (kBtu/kWh) * Distribution Efficiency

= Actual. If unknown, use the table C403.2.3(2) in IECC 2012 (or IECC 2018 if through new construction) to assume values based on code estimates, and assume 95% distribution efficiency.

[1701] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[1702] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1703] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): Ch 16.1 - 16.37.

Note IECC 2018 became effective July 1, 2019 and is the baseline for all New Construction permits from that date.

$t_{standard}$ = average hours per day the standard speed door is open (hr/day)

(see calculation in 'Time door is open' section below)

t_{fast} = average hours per day the high speed door is open (hr/day)

(see calculation in 'Time door is open' section below)

CD = cooling days per year, total days in year above balance point temperature (day)

= use table below to select the best value for location:[1704]

	CD (Balance Point Temperature)				
Climate Zone -Weather Station/City	45 °F	50 °F	55 °F	60 °F	65 °F
1 - Rockford AP / Rockford	194	168	148	124	97
2 - Chicago O'Hare AP / Chicago	194	173	153	127	95
3 - Springfield #2 / Springfield	214	194	174	148	114
4 - Belleville SIU RSCH / Belleville	258	229	208	174	138
5 - Carbondale Southern IL AP / Marion	222	201	181	158	130

HSPF2 = Heating System Performance Factor of heat pump equipment * Distribution Efficiency

= Actual. If unknown, use the table C403.2.3(2) in IECC 2012 (or IECC 2018 if through new construction) to assume values based on code estimates, and assume 95% distribution efficiency.

Note IECC 2018 became effective July 1, 2019 and is the baseline for all New Construction permits from that date.

HD = heating days per year, total days in year above balance point temperature (day)

= use table below to select an appropriate value:[1705]

	HD				
Climate Zone Weather Station/City	45 °F	50 °F	55 °F	60 °F	65 °F
1 - Rockford AP / Rockford	142	160	183	204	228
2 - Chicago O'Hare AP / Chicago	150	166	192	219	253
3 - Springfield #2 / Springfield	125	142	167	194	230
4 - Belleville SIU RSCH / Belleville	101	115	134	156	180
5 - Carbondale Southern IL AP / Marion	103	123	148	174	205

Time Door is Open

$t_{standard}$ $= CyclesPerDay * [Hd * 12 * (1 / Speed_{open_standard} + 1 / Speed_{close_standard})] / 3600$

[1704] National Solar Radiation Data Base – 1991 – 2005 Update: Typical Meteorological Year 3, NREL. Note that cooling days (CD) are calculated by first determining its value from the TMY3 data associated with the appropriate weather station as defined by and used elsewhere in the Illinois TRM. Using the TMY3 outdoor air dry bulb hourly data, the annual hours are totaled for every hour that the outdoor air dry bulb temperature is above a designated zero heat loss balance point temperature or base temperature for cooling. For commercial and industrial (C&I) buildings, a base temperature for heating of 55 oF is designated in the Illinois TRM, but building specific base temperatures are recommended for large C&I projects. Additionally, the TRM uses a 30-year normal data for degree-days while the CD calculation was based on TMY3 data; in order to account for this, calculations of CD were also normalized by the ratio of CDD to align the calculated values more closely with the TRM.

[1705] Note that Heating Days (HD) are calculated following the same approach outlined in the Cooling Days section.

t_{fast} = $CyclesPerDay * [Hd * 12 * (1 / Speed_{open_fast} + 1 / Speed_{close_fast})] / 3600$

Where:

CyclesPerDay = the number of door opening and closing cycles per day

= Actual. If unknown, use 75[1706] or for parking garages calculate based on the number of parking spaces[1707].

H_d = the height of the doorway (ft)

= user input

12 = unit conversion from feet to inches

$Speed_{open}$ = the speed (inches/second) at which the door opens

= Actual. If unknown, use 32 inches/second for high speed[1708], use 8 inches/second for standard speed[1709]

$Speed_{close}$ = the speed (inches/second) at which the door closes

= Actual. If unknown, use 24 inches/second for high speed[1710], = 8 inches/second for standard speed[1711]

3600 = unit conversion from seconds to hours

Heat Transfer Through Open Entryway (Cooling Season)

Q = $4.5 * CFM_{tot} * (h_{oc} - h_{ic}) / (1{,}000\ Btu/kBtu)$

Where:

4.5 = unit conversion factor with density of air: 60 min/hr * 0.075 lbm/ft^3 (lb*min/(ft*hr))

CFM_{tot} = Total air flow through entryway (cfm), see calculation below

h_{oc} = average enthalpy of outside air during the cooling season (Btu/lb)

= use the below table to determine the approximate outdoor air enthalpy associated with an indoor temperature setpoint and climate zone.[1712]

	h_{oc}		
Climate Zone -Weather Station/City	**67 °F**	**72 °F**	**77 °F**
1 - Rockford AP / Rockford	31.6	33.0	35.3
2 - Chicago O'Hare AP / Chicago	32.0	33.6	35.4
3 - Springfield #2 / Springfield	32.9	34.6	36.6
4 - Belleville SIU RSCH / Belleville	33.5	35.0	36.4
5 - Carbondale Southern IL AP / Marion	34.6	36.2	37.7

[1707] ASHRAE, "Enclosed Vehicular Facilities – Parking Garages," in 2019 ASHRAE Handbook – HVAC Applications (2019): p. 16.18 to 16.20. Number of cars operating is 3-5% (use 4% as average) per hour of the total vehicle capacity, making openings per day = 4% * number of parking spaces * 24 hours per day * 2 (car will enter and leave once per day).
[1708] DASMA Standard 403-2020, "Specification for High Speed Doors and Grilles", DASMA Standard (2020): Section 2.6.
[1709] Wendt, Jeff, "When a High-Speed Door is More Energy Efficient", Door & Access Systems Magazine – Tech Tips. Sept. 2014.
[1710] DASMA Standard 403-2020, "Specification for High Speed Doors and Grilles", DASMA Standard (2020): Section 2.6.
[1711] Wendt, Jeff, "When a High-Speed Door is More Energy Efficient", Door & Access Systems Magazine – Tech Tips. Sept. 2014.
[1712] Average enthalpies were estimated following ASHRAE guidelines for perfect gas relationships for dry air associated with hourly TMY3 data. Enthalpies were then averaged for all values associated with a dry-bulb outdoor air temperature that exceeded the indoor air temperature setpoint. Other enthalpy values may be interpolated for indoor air temperature setpoints not represented in the table. Note that while outdoor air enthalpies increase with higher temperature setpoints, the change in enthalpy from indoor to outdoor will decrease.

h_{ic} = average enthalpy of indoor air, cooling season (Btu/lb)

= use the below table to determine the approximate indoor air enthalpy associated with an indoor temperature setpoint in indoor relative humidity.

	h_{ic}		
Relative Humidity (%)	**67 °F**	**72 °F**	**77 °F**
60	25.5	28.5	31.8
50	23.9	26.6	29.5
40	22.3	24.7	27.3

= an estimate 26.6 Btu/lb associated with the 72 °F and 50% indoor relative humidity case can be used as an approximation if no other data is available. For other indoor temperature setpoints and RH, enthalpies may be interpolated.

The total airflow through the entryway, CFM_{tot}, includes both infiltration due to wind as well as thermal forces, as follows:

CFM_{tot} = $sqrt[\ (CFM_w)^2\ +\ (CFM_t{}^2)\ ]$

Where:

CFM_w = Infiltration due to the wind (cfm)

CFM_t = Infiltration due to thermal forces (cfm)

The infiltration due to the wind is calculated as follows:

CFM_w = $(v_{wc}\ *\ C_{wc})*\ C_v\ *\ A_d\ *\ (88\ fpm/mph)$

Where:

v_{wc} = average wind speed during the cooling season based on entryway orientation (mph)

= use the below table to for the wind speed effects based on climate zone and entryway orientation:[1713]

	Entryway Orientation				
Climate Zone -Weather Station /City	**N**	**E**	**S**	**W**	**Unknown (average)**
1 - Rockford AP / Rockford	4.2	4.1	4.7	4.8	4.5
2 - Chicago O'Hare AP / Chicago	4.7	4.5	5.4	4.6	4.8
3 - Springfield #2 / Springfield	4.1	3.7	6.0	5.0	4.7
4 - Belleville SIU RSCH / Belleville	3.3	2.7	3.8	4.2	3.5
5 - Carbondale Southern IL AP / Marion	3.1	2.9	4.4	3.8	3.6

[1713] Average wind speeds are calculated based on the TMY3 wind speed data. Because this data is collected at an altitude of 33 ft, wind speed is approximated for a 5 ft level based on ASHRAE Handbook guidelines using the urban/suburban parameters for adjusting wind speed based on altitude (Layer thickness (ft) δ = 1200, Exponent a = 0.22).
ASHRAE, "Airflow Around Buildings," in 2013 ASHRAE Handbook – Fundamentals (2013): p 24.3.

C_{wc} = wind speed correction factor due to wind direction in cooling season (%)

= because wind direction is not constant, a wind speed correction factor is used to adjust for the amount of time during the cooling season prevailing winds can be expected to impact the entryway. Use the following table to determine the correct wind speed correction factor for cooling applications.

	Entryway Orientation				
Climate Zone -Weather Station/City	N	E	S	W	Unknown (Average)
1 - Rockford AP / Rockford	0.18	0.13	0.30	0.31	0.23
2 - Chicago O'Hare AP / Chicago	0.18	0.17	0.36	0.26	0.24
3 - Springfield #2 / Springfield	0.17	0.12	0.46	0.21	0.24
4 - Belleville SIU RSCH / Belleville	0.21	0.15	0.35	0.16	0.22
5 - Carbondale Southern IL AP / Marion	0.18	0.15	0.37	0.11	0.20

Note that correction factors do not add up to 1 (100%). This is attributed to periods of calm winds.

C_v = effectiveness of openings,

= 0.3, assumes diagonal wind[1714]

A_d = area of the doorway (ft^2)

= user defined

The infiltration due to thermal forces is calculated as follows:

$CFM_t = A_d * C_{dc} * (60 \text{ sec/min}) * \text{sqrt}[2 * g * H_d/2 * (T_{oc} - T_{ic}) / (459.7 + T_{oc})]$

Where:

C_{dc} = the discharge coefficient during the cooling season[1715]

$= 0.4 + 0.0025 * |T_{ic} - T_{oc}|$

Note, values for C_{dc} show little variation due to balance point temperature, indoor air temperature, and climate zone. As such, if estimating results, the Illinois average value of 0.42 at indoor air temp of 72°F may be used as a simplification.

g = acceleration due to gravity

= 32.2 ft/sec^2

T_{ic} = Average indoor air temperature during cooling season

= User input, can assume indoor cooling temperature set-point

T_{oc} = Average outdoor temp during cooling season (°F)

= the average outdoor temperature is dependent on the CD period and zone. As such, the following table may be used for average outdoor temperature during the cooling period:[1716]

	T_{oc}				
Climate Zone Weather Station/City	62 °F	67 °F	72 °F	77 °F	82 °F
1 - Rockford AP / Rockford	72.9	76.0	79.2	82.5	85.5

[1714] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): p 16.13

[1715] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): p 16.13.

[1716] Based on binned data from TMY3 & adjusted bracketed thermostat setpoint temperatures. Interpolate other values as needed.

	T_{oc}				
2 - Chicago O'Hare AP / Chicago	72.9	76.0	79.4	82.8	85.5
3 - Springfield #2 / Springfield	73.7	76.7	79.9	83.4	86.4
4 - Belleville SIU RSCH / Belleville	74.9	77.7	81.0	84.3	86.9
5 - Carbondale Southern IL AP / Marion	75.1	77.7	80.9	84.7	87.4

459.7 = conversion factor from °F to °R

= calculation requires absolute temperature for values not calculated as a difference of temperatures.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (\Delta kWh_{cooling} / (CD * 24)) * CF$$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%[1717]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1718]

FOSSIL FUEL SAVINGS

Natural gas savings, Δtherms, associated with reduced infiltration through an entryway during the heating season are calculated by determining the difference between heat loss through the entryway before and after the installation of the high speed overhead door.

$$\Delta therms = Q * (t_{standard} - t_{fast}) * HD / \eta Heat$$

Where:

Q = rate of sensible heat transfer through the open entryway, before air curtain (therm/hr)

$t_{standard}$ = average hours per day the standard speed door is open (hr/day)

(see calculation in 'Time door is open' heading of Electric Energy Savings section)

t_{fast} = average hours per day the high speed door is open (hr/day)

(see calculation in 'Time door is open' heading of Electric Energy Savings section)

HD = heating days per year, total days in year above balance point temperature (day)

= use table below to select an appropriate value:[1719]

	HD				
Climate Zone - Weather Station/City	45 °F	50 °F	55 °F	60 °F	65 °F
1 - Rockford AP / Rockford	142	160	183	204	228
2 - Chicago O'Hare AP / Chicago	150	166	192	219	253
3 - Springfield #2 / Springfield	125	142	167	194	230
4 - Belleville SIU RSCH / Belleville	101	115	134	156	180

[1717] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1718] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year

[1719] Note that Heating Days (HD) are calculated following the same approach outlined in the Cooling Days section.

	HD				
Climate Zone - Weather Station/City	45 °F	50 °F	55 °F	60 °F	65 °F
5 - Carbondale Southern IL AP / Marion	103	123	148	174	205

ηHeat = Efficiency of heating system, including distribution losses.

= Actual, if unknown assume a value of 0.821.[1720]

Heat Transfer Through Open Entryway (Heating Season)

Q $= 1.08 * CFM_{tot} * (T_{ih} - T_{oh}) / (100{,}000\ Btu/therm)$

Where:

1.08 = sensible heat transfer coefficient: specific heat of air and unit conversions, Btu/(hr*°F*cfm)

CFM_{tot} = Total air flow through entryway (cfm)

T_{ih} = Average indoor air temperature during heating season

= User input, can assume indoor heating temperature set-point

T_{oh} = Average outdoor temp during heating season (°F)

= use table below, based on binned data from TMY3 & balance point temperature:

	Avg Outdoor Air Temp - Heating Season				
Climate Zone -Weather Station/City	45 °F	50 °F	55 °F	60 °F	65 °F
1 - Rockford AP / Rockford	26.3	28.8	31.6	34.2	37.3
2 - Chicago O'Hare AP / Chicago	29.4	31.2	34.0	36.8	40.3
3 - Springfield #2 / Springfield	29.4	31.5	34.6	37.7	41.6
4 - Belleville SIU RSCH / Belleville	31.7	33.6	36.2	39.2	42.3
5 - Carbondale Southern IL AP / Marion	32.5	34.9	37.8	40.7	44.0

The total airflow through the entryway, CFM_{tot}, includes both infiltration due to wind as well as thermal forces, as follows:

CFM_{tot} = sqrt[$(CFM_w)^2 + (CFM_t^2)$]

Where:

CFM_w = Infiltration due to the wind (cfm)

CFM_t = Infiltration due to thermal forces (cfm)

The infiltration due to the wind is calculated as follows:

CFM_w = $(v_{wh} * C_{wh}) * C_v * A_d$ * (88 fpm/mph)

Where:

v_{wh} = average wind speed during the heating season (mph)

= similar to cooling season wind speed assumptions, use the following table to determined average wind speed based on entryway orientation:

1720 Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

	Entryway Orientation			
Climate Zone -Weather Station/ City	N	E	S	W
1 - Rockford AP / Rockford	5.0	4.6	4.9	5.6
2 - Chicago O'Hare AP / Chicago	5.5	5.2	4.9	5.1
3 - Springfield #2 / Springfield	5.0	4.9	5.3	5.1
4 - Belleville SIU RSCH / Belleville	4.3	3.4	3.5	5.3
5 - Carbondale Southern IL AP / Marion	4.6	3.2	4.2	4.4

C_{wh} = wind speed correction factor due to wind direction in heating season, (%)

= because wind direction is not constant, a wind speed correction factor is used to adjust for the amount of time during the heating season prevailing winds can be expected to impact the entryway. Use the following table to determine the correct wind speed correction factor for the heating applications.

	Entryway Orientation			
Climate Zone -Weather Station/ City	N	E	S	W
1 - Rockford AP / Rockford	0.18	0.13	0.30	0.31
2 - Chicago O'Hare AP / Chicago	0.21	0.10	0.26	0.39
3 - Springfield #2 / Springfield	0.21	0.14	0.27	0.34
4 - Belleville SIU RSCH / Belleville	0.31	0.15	0.22	0.29
5 - Carbondale Southern IL AP / Marion	0.31	0.11	0.27	0.18

Note that correction factors do not add up to 1 (100%). This is attributed to periods of calm winds.

C_v = effectiveness of openings,

= 0.3, assumes diagonal wind[1721]

A_d = area of the doorway (ft^2)

= user input

The infiltration due to thermal forces is calculated as follows:

$CFM_t = A_d * C_{dh} * (60\ sec/min) * sqrt[2 * g * H/2 * (T_{ih} – T_{oh}) / (459.7 + T_{ih})]$

Where:

C_{dh} = the discharge coefficient during the heating season

$= 0.4 + 0.0025 * |T_{ih} – T_{oh}|$

Note, values for C_{dh} show little variation due to balance point temperature, indoor air temperature, and climate zone. As such, if estimating results, the Illinois average value of 0.49 at indoor air temp of 72°F may be used as a simplification.

g = acceleration due to gravity

= 32.2 ft/sec^2

H = the height of the entryway (ft)

= user defined

DEEMED O&M COST ADJUSTMENT CALCULATION

Manufacturers suggest annual inspection and maintenance (such as patching tears) of high speed doors. At a minimum, greasing of fittings and oil top-off should be carried out annually. This is estimated at a cost of $150 per year.[1722]

MEASURE CODE: CI-SHL-HSOD-V02-260101

REVIEW DEADLINE: 1/1/2028

[1722]Assumes approximately 1 hour of maintenance, based on manufacturer product spec sheets.

4.8.6 Dock Door Seals and Shelter

DESCRIPTION

This measure applies to buildings with exterior doors that serve as loading docks.

Overhead dock doors allow for loading and unloading of trucks. When the truck backs into the dock bumpers, a gap is created between the truck and the dock door that allows the infiltration or exfiltration of air in the upper, lower, and side portions. The infiltration/exfiltration of cold and warm air during the heating and cooling seasons increases the energy load of the building. Dock door seals are foam panels that are mounted outside of the dock door. Dock shelters are structures that form an enclosure around the perimeter of the trailer and are mounted outside of the dock door. The addition of dock door seals and shelters forms a tight seal between the truck and the door that prevents air infiltration/exfiltration and results in energy savings and enhanced personal comfort. Dock door seals and shelters also prevent the passing of rain droplets, snow, dust, insects, and other airborne particles.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Dock doors with compression seals or shelters forming a tight seal around the top, bottom, and sides of the truck and installed following manufacturer guidelines to effectively reduce heat loss and air during truck loading and unloading.

DEFINITION OF BASELINE EQUIPMENT

Dock doors with no seals or shelters installed to effectively reduce heat loss and air during truck loading and unloading.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years[1723].

DEEMED MEASURE COST

The capital cost for dock door seals for exterior entryways is $3,692[1724].

LOADSHAPE

Heating season: If electric heating, use Commercial Electric heating Loadscape, C04. Otherwise, N/A

Cooling seasons: Commercial Cooling Loadshape C03. Or, if applicable, use Commercial Electric Heating and Cooling Loadshape C05.

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%[1725]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

[1723] California Statewide Codes and Standards Enhancement (CASE) Program. "Dock Seals – Final Report". California, November 2017.

[1724] Based on average project cost for dock door shelters incentivized under PG NSG Energy Efficiency programs between 2018 and 2020. Shelter average size is 85 square feet.

[1725] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

= 47.8% [1726]

Algorithm

CALCULATION OF ENERGY SAVINGS

The formulas follow the calculation methodology outlined by the ASHARE Handbook[1727] as stated in measure 4.4.33 Industrial Air Curtains.

ELECTRIC ENERGY SAVINGS

$\Delta kWh_{cooling} = Q_{tbs} * t_{open} * CD / EER2$

$\Delta kWh_{heating} = Q_{bs} * t_{open} * HD * (100\ kBtu/therm)/(HSPF2 * (3.412\ kBtu/kWh))$

Where:

Q_{tbs} = rate of total heat transfer through the gap before dock door seal or shelter [kBtu/hr]

t_{open} = average hours per day that a truck is in the loading position and the truck dock door is open [hr/day]

= 8.39 hours[1728] or actual.

CD = cooling days per year, total days in year above balance point temperature (day)

= use table below to select the best value for location, or 55°F if unknown:[1729]

.	CD (Balance Point Temperature)				
Climate Zone -Weather Station/City	45°F	50°F	55°F	60°F	65°F
1 - Rockford AP / Rockford	194	168	148	124	97
2 - Chicago O'Hare AP / Chicago	194	173	153	127	95
3 - Springfield #2 / Springfield	214	194	174	148	114
4 - Belleville SIU RSCH / Belleville	258	229	208	174	138
5 - Carbondale Southern IL AP / Marion	222	201	181	158	130

EER2 = energy efficiency ratio of the cooling equipment (kBtu/kWh) * distribution efficiency

= Actual. If unknown, use the table C403.2.3(2) in IECC 2012 (or IECC 2018 if through new construction) to assume values based on code estimates, and assume 95% distribution efficiency for central cooling with ducts.

HSPF2 = Heating System Performance Factor of heat pump equipment * distribution efficiency

[1726] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1727] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): Ch 16.1 - 16.37.
[1728] Assumes 23-hour per day operation 5 days per week, with an average loading time of 45 minutes (including truck arrival and departure time) taken from: https://www.novalocks.com/wp-content/uploads/Dock-Planning-Standards-Guide.pdf. Average time between trucks estimated at 90 minutes taken from customer interviews. 5 day/7 days * 23 hr/day / 90 minutes per truck event x 45 minutes door open time per truck event = 8.39 average hr/day, 7 days/week.
[1729] National Solar Radiation Data Base – 1991 – 2005 Update: Typical Meteorological Year 3, NREL.
Note that cooling days (CD) are calculated by first determining its value from the TMY3 data associated with the appropriate weather station as defined by and used elsewhere in the Illinois TRM. Using the TMY3 outdoor air-dry bulb hourly data, the annual hours are totaled for every hour that the outdoor air-dry bulb temperature is above a designated zero heat loss balance point temperature or base temperature for cooling. For commercial and industrial (C&I) buildings, a base temperature for heating of 55°F is designated in the Illinois TRM, but building specific base temperatures are recommended for large C&I projects. Additionally, the TRM uses a 30-year normal data for degree-days while the CD calculation was based on TMY3 data; in order to account for this, calculations of CD were also normalized by the ratio of CDD to align the calculated values more closely with the TRM.

= Actual. If unknown, use the table C403.2.3(2) in IECC 2012 (or IECC 2018 if through new construction) to assume values based on code estimates, and assume 95% distribution efficiency for central cooling with ducts.

HD = heating days per year, total days in year above balance point temperature [day]

= use table below to select an appropriate value, or 55°F if unknown:[1730]

	HD				
Climate Zone Weather Station/City	**45°F**	**50°F**	**55°F**	**60°F**	**65° F**
1 - Rockford AP / Rockford	142	160	183	204	228
2 - Chicago O'Hare AP / Chicago	150	166	192	219	253
3 - Springfield #2 / Springfield	125	142	167	194	230
4 - Belleville SIU RSCH / Belleville	101	115	134	156	180
5 - Carbondale Southern IL AP / Marion	103	123	148	174	205

Heat Transfer Through Open Dock Door Without Dock Door Seal or Shelter (during Cooling Season)

Q_{tbs} = 4.5 * CFM_{tot} *(h_{oc} – h_{ic}) / (1,000 Btu/kBtu)

4.5 = unit conversion factor with density of air: 60min/hr * 0.075 lbm/ft^3 (lbm * min / (ft^3 * hr))

CFM_{tot} = total air flow through dock door (CFM)

h_{oc} = average enthalpy of outside air during the cooling season (Btu/lb)

= use the below table to determine the approximate outdoor air enthalpy associated with an indoor temperature setpoint and climate zone, use 72°F if unknown.[1731]

	h_{oc}		
Climate Zone -Weather Station/City	**67°F**	**72°F**	**77°F**
1 - Rockford AP / Rockford	31.6	33.0	35.3
2 - Chicago O'Hare AP / Chicago	32.0	33.6	35.4
3 - Springfield #2 / Springfield	32.9	34.6	36.6
4 - Belleville SIU RSCH / Belleville	33.5	35.0	36.4
5 - Carbondale Southern IL AP / Marion	34.6	36.2	37.7

h_{ic} = average enthalpy of indoor air, cooling season (Btu/lb) point temperature

= use the below table to determine the approximate indoor air enthalpy associated with an indoor temperature setpoint in indoor relative humidity.

	h_{ic}		
Relative Humidity (%)	**67°F**	**72°F**	**77°F**
60	25.5	28.5	31.8
50	23.9	26.6	29.5
40	22.3	24.7	27.3

[1730] Note that Heating Days (HD) are calculated following the same approach outlined in the Cooling Days section.

[1731] Average enthalpies were estimated following ASHRAE guidelines for perfect gas relationships for dry air associated with hourly TMY3 data. Enthalpies were then averaged for all values associated with a dry-bulb outdoor air temperature that exceeded the indoor air temperature setpoint. Other enthalpy values may be interpolated for indoor air temperature setpoints not represented in the table. Note that while outdoor air enthalpies increase with higher temperature setpoints, the change in enthalpy from indoor to outdoor will decrease.

= an estimate 26.6 Btu/lb associated with the 72°F and 50% indoor relative humidity case can be used as an approximation if no other data is available. For other indoor temperature setpoints and RH, enthalpies may be interpolated.

The total airflow through the gaps, CFM_{tot}, includes both infiltration due to wind as well as thermal forces, as follows:

$CFM_{tot} = sqrt[(CFM_w)^2 + (CFM_t^2)]$

Where:

CFM_w = Infiltration due to the wind (cfm)

CFM_t = Infiltration due to thermal forces (cfm)

The infiltration due to the wind is calculated as follows:

$CFM_w = (v_{wc} * C_{wc}) * C_v * L_a * (88 \text{ fpm/mph})$

Where:

v_{wc} = average wind speed during the cooling season based on entryway orientation (mph)

= use the below table to for the wind speed effects based on climate zone and entryway orientation:[1732]

	Entryway Orientation				
Climate Zone -Weather Station /City	N	E	S	W	Unknown (average)
1 - Rockford AP / Rockford	4.2	4.1	4.7	4.8	4.5
2 - Chicago O'Hare AP / Chicago	4.7	4.5	5.4	4.6	4.8
3 - Springfield #2 / Springfield	4.1	3.7	6.0	5.0	4.7
4 - Belleville SIU RSCH / Belleville	3.3	2.7	3.8	4.2	3.5
5 - Carbondale Southern IL AP / Marion	3.1	2.9	4.4	3.8	3.6

C_{wc} = wind speed correction factor due to wind direction in cooling season (%)

= because wind direction is not constant, a wind speed correction factor is used to adjust for the amount of time during the cooling season that prevailing winds can be expected to impact the entryway. Use the following table to determine the correct wind speed correction factor for cooling applications.

	Entryway Orientation				
Climate Zone -Weather Station/City	N	E	S	W	Unknown (Average)
1 - Rockford AP / Rockford	0.18	0.13	0.30	0.31	0.23
2 - Chicago O'Hare AP / Chicago	0.18	0.17	0.36	0.26	0.24
3 - Springfield #2 / Springfield	0.17	0.12	0.46	0.21	0.24
4 - Belleville SIU RSCH / Belleville	0.21	0.15	0.35	0.16	0.22
5 - Carbondale Southern IL AP / Marion	0.18	0.15	0.37	0.11	0.20

[1732] Average wind speeds are calculated based on the TMY3 wind speed data. Because this data is collected at an altitude of 33 ft, wind speed is approximated for a 5 ft level based on ASHRAE Handbook guidelines using the urban/suburban parameters for adjusting wind speed based on altitude (Layer thickness (ft) δ = 1200, Exponent a = 0.22).
ASHRAE, "Airflow Around Buildings," in 2013 ASHRAE Handbook – Fundamentals (2013): p 24.3.

Note that correction factors do not add up to 1 (100%). This is attributed to periods of calm winds.

C_v = effectiveness of openings,

= 0.3, assumes diagonal wind[1733]

L_a = Leakage Area (gap) between doorway and truck (ft^2)

= 16.8 feet[1734] or Actual.

The infiltration due to thermal forces is calculated as follows:

$CFM_t = L_a * C_{dc} * (60\ sec/min) * sqrt[2 * g * H/2 * (T_{oc} - T_{ic}) / (459.7 + T_{oc})]$

Where:

C_{dc} = the discharge coefficient during the cooling season[1735]

$= 0.4 + 0.0025 * |T_{ic} - T_{oc}|$

= 0.42, Illinois average at indoor air temp of 72°F

Note, values for C_{dc} show little variation due to balance point temperature, indoor air temperature, and climate zone. As such, if estimating results, the Illinois average value may be used as a simplification.

g = acceleration due to gravity

$= 32.2\ ft/sec^2$

H = dock door height (ft)

= user input

T_{ic} = Average indoor air temperature during cooling season

= User input, can assume indoor cooling temperature set-point

T_{oc} = Average outdoor temp during cooling season (°F)

= the average outdoor temperature is dependent on the CD period and zone. As such, the following table may be used for average outdoor temperature during the cooling period:[1736]

	T_{oc}				
Climate Zone Weather Station/City	**62 °F**	**67 °F**	**72 °F**	**77 °F**	**82 °F**
1 - Rockford AP / Rockford	72.9	76.0	79.2	82.5	85.5
2 - Chicago O'Hare AP / Chicago	72.9	76.0	79.4	82.8	85.5
3 - Springfield #2 / Springfield	73.7	76.7	79.9	83.4	86.4
4 - Belleville SIU RSCH / Belleville	74.9	77.7	81.0	84.3	86.9
5 - Carbondale Southern IL AP / Marion	75.1	77.7	80.9	84.7	87.4

459.7 = conversion factor from °F to °R

[1733] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): p 16.13

[1734] Estimated 16.8 square feet of gap area. The leakage area is comprised of gaps on top, bottom and on the sides of the dock door. Common dock door dimensions are 8'0" in width with 8 ft, 9 ft or 10 ft heights. The maximum trailer size limits are 8'6" wide x 13'6" high (varies by state). Most trucks require a dock height of between 46 and 52 in. For the purposes of this calculation a 48" dock height and 9'0" wide x 10'0" high door was use, to cover the full range of truck types.

[1735] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): p 16.13.

[1736] Based on binned data from TMY3 & adjusted bracketed thermostat setpoint temperatures. Interpolate other values as needed.

= calculation requires absolute temperature for values not calculated as a difference of temperatures.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$\Delta kW = (\Delta kWh_{cooling} / (CD * 24)) * CF$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%[1737]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1738]

FOSSIL FUEL SAVINGS

Natural Gas savings associated with reduced infiltration through the gaps between the truck and the dock door during the heating season are calculated with the following formula:

$\Delta therms = Q_{bs} * t_{open} * HD / \eta Heat$

Where:

Q_{bs} = rate of sensible heat transfer through the gaps before dock door seal or shelter (therm/hr)

t_{open} = average hours per day the door is open (hr/day)

= 8.25[1739] hours or actual.

HD = heating days per year, as defined above

ηHeat = efficiency of heating equipment * Distribution Efficiency

= Actual, if unknown assume code baseline and assume 95% distribution efficiency. For midstream prorams, assume a value of 0.821.[1740]

Heat Transfer Through Dock Door without Dock Door Seals or Shelters (Heating Season)

$Q_{bs} = (1.08 \text{ Btu}/(\text{hr}*°\text{F}*\text{cfm})) * CFM_{tot} * (T_{ih} - T_{oh}) / (100{,}000 \text{ Btu/therm})$

Where:

1.08 = sensible heat transfer coefficient (specific heat of air and unit conversions)

CFM_{tot} = Total air flow through gaps (cfm)

T_{ih} = Average indoor air temperature during heating season

= User input, can assume indoor heating temperature set-point

T_{oh} = Average outdoor temp during heating season (°F)

[1737] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1738]Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year

[1739] Average loading time estimated at 45 minutes including truck arrival and departure time from: https://www.novalocks.com/wp-content/uploads/Dock-Planning-Standards-Guide.pdf. Average time between truck departure and arrival estimated at 90 minutes taken from customer interviews.

[1740] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

= use table below, based on binned data from TMY3 & balance point temperature:

	Avg Outdoor Air Temp - Heating Season				
Climate Zone -Weather Station/City	45°F	50°F	55°F	60°F	65°F
1 - Rockford AP / Rockford	26.3	28.8	31.6	34.2	37.3
2 - Chicago O'Hare AP / Chicago	29.4	31.2	34.0	36.8	40.3
3 - Springfield #2 / Springfield	29.4	31.5	34.6	37.7	41.6
4 - Belleville SIU RSCH / Belleville	31.7	33.6	36.2	39.2	42.3
5 - Carbondale Southern IL AP / Marion	32.5	34.9	37.8	40.7	44.0

The total airflow through the gaps, CFM_{tot}, includes both infiltration due to wind as well as thermal forces, as follows:

$CFM_{tot} = \text{sqrt}[(CFM_w)^2 + (CFM_t^2)]$

Where:

CFM_w = Infiltration due to the wind (cfm)

CFM_t = Infiltration due to thermal forces (cfm)

The infiltration due to the wind is calculated as follows:

$CFM_w = (v_{wh} * C_{wh}) * C_v * L_a * (88 \text{ fpm/mph})$

Where:

v_{wh} = average wind speed during the heating season (mph)

= similar to cooling season wind speed assumptions, use the following table to determine average wind speed based on entryway orientation:

	Entryway Orientation				
Climate Zone -Weather Station/ City	N	E	S	W	Average (unknown)
1 - Rockford AP / Rockford	5.0	4.6	4.9	5.6	5.0
2 - Chicago O'Hare AP / Chicago	5.5	5.2	4.9	5.1	5.2
3 - Springfield #2 / Springfield	5.0	4.9	5.3	5.1	5.1
4 - Belleville SIU RSCH / Belleville	4.3	3.4	3.5	5.3	4.1
5 - Carbondale Southern IL AP / Marion	4.6	3.2	4.2	4.4	4.1

C_{wh} = wind speed correction factor due to wind direction in heating season, (%)

= because wind direction is not constant, a wind speed correction factor is used to adjust for the amount of time during the heating season prevailing winds can be expected to impact the entryway. Use the following table to determine the correct wind speed correction factor for the heating applications.

	Entryway Orientation				
Climate Zone -Weather Station/ City	N	E	S	W	Average (unknown)
1 - Rockford AP / Rockford	0.18	0.13	0.30	0.31	0.23
2 - Chicago O'Hare AP / Chicago	0.21	0.10	0.26	0.39	0.24
3 - Springfield #2 / Springfield	0.21	0.14	0.27	0.34	0.24
4 - Belleville SIU RSCH / Belleville	0.31	0.15	0.22	0.29	0.24
5 - Carbondale Southern IL AP / Marion	0.31	0.11	0.27	0.18	0.22

Note that correction factors do not add up to 1 (100%). This is attributed to periods of calm winds.

C_v = effectiveness of openings,

= 0.3, assumes diagonal wind[1741]

L_a = Leakage Area (gap) between doorway and truck (ft^2)

= 16.8 feet[1742] or Actual.

The infiltration due to thermal forces is calculated as follows:

$CFM_t = L_a * C_{dh} * (60 \text{ sec/min}) * \text{sqrt}[2 * g * H/2 * (T_{ih} – T_{oh}) / (459.7 + T_{ih})]$

Where:

C_{dh} = the discharge coefficient during the heating season

$= 0.4 + 0.0025 * |T_{ih} – T_{oh}|$

= 0.49, Illinois average at indoor air temp of 72°F

Note, values for C_{dh} show little variation due to balance point temperature, indoor air temperature, and climate zone. As such, if estimating results, the Illinois average value may be used as a simplification.

g = acceleration due to gravity

= 32.2 ft/sec^2

H = dock door height (ft)

= user defined

MEASURE CODE: CI-SHL-DDSS-V02-260101

REVIEW DEADLINE: 1/1/2028

[1741] ASHRAE, "Ventilation and Infiltration," in 2013 ASHRAE Handbook – Fundamentals (2013): p 16.13

[1742] Estimated 16.8 square feet of gap area. The leakage area is comprised of gaps on top, bottom and on the sides of the dock door. Common dock door dimensions are 8'0" in width with 8 ft, 9 ft or 10 ft heights. The maximum trailer size limits are 8'6" wide x 13'6" high (varies by state). Most trucks require a dock height of between 46 and 52 in. For the purposes of this calculation a 48" dock height and 9'0" wide x 10'0" high door was use, to cover the full range of truck types.

4.8.7 Commercial Wall Insulation

DESCRIPTION

Wall insulation is added to building wall cavities or to building internal/external wall surfaces; foundation insulation is added to building internal/external foundation surfaces, both above grade and below grade. This measure requires pre- and post-implementation R-values and measurements surface areas.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient scenario is the installation of added insulation. This measure requires a member of the implementation staff or a participating contractor to evaluate the pre- and post-implementation R-values and to measure surface areas. The requirements for participation in the program will be defined by the utilities.

DEFINITION OF BASELINE EQUIPMENT

The existing condition will be evaluated by implementation staff or a participating contractor and is likely to be empty or minimally insulated wall cavities, and uninsulated above and below grade foundation walls.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 25 years.[1743]

DEEMED MEASURE COST

Costs can be highly variable due to differences in building type and structural assemblies and therefore actual costs should be used when possible. Absent of actual cost information, estimated costs can be used. Per the W017 Itron California Measure Cost Study,[1744] the material cost for different assemblies and R-values can be assumed as follows:

Dimensions	R-value	Equipment Cost per sq.ft.	Labor Cost per sq.ft.	Incremental Cost per sq.ft.
2x4	R-15	$0.34	$0.81	$1.15
2x6	R-19	$0.41	$0.81	$1.22
2x6	R-21	$0.44	$0.81	$1.25

LOADSHAPE

Loadshape C01 – Commercial Electric Cooling

Loadshape C03 – Commercial Cooling

Loadshape C04 – Commercial Electric Heating

Loadshape C05 – Commercial Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's

[1743] Navigant 'ComEd Effective Useful Life Research Report', May 2018.

[1744] Measure costs are from the "2010-2012 WO017 Ex Ante Measure Cost Study", Itron, California Public Utilities Commission, May 2014. The data is provided in a file named "MCS Results Matrix – Volume I".

capacity market. Both values provided are based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren.

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1745]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1746]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Where available, savings from wall and foundation insulation measures should be determined through a custom analysis. When that is not feasible for the program the following engineering algorithms can be used.

$$\Delta kWh = \Delta kWh_cooling + \Delta kWh_heatingElectric + \Delta kWh_heatingGas$$

Where:

ΔkWh_cooling = If building is cooled, reduction in annual cooling requirement due to wall insulation

$$= [(1 / R_ExistWall - 1 / R_NewWall) * A_wall + (1 / R_ExistAG - 1 / R_NewAG) * A_AG + (1 / R_ExistBG - 1 / R_NewBG) * A_BG] * EFLH_{cooling} * \Delta T_{FL,cooling} / 1000 / \eta Cool * \%Cool$$

Where:

R_NewWall = R-value of proposed new wall assembly (including all layers between inside air and outside air).

= Actual

R_ExistWall = R-value value of existing assembly and any existing insulation.

= Minimum of R-5 for uninsulated assemblies[1747]

A_wall = Net area of insulated wall (ft^2)

= Actual

R_NewAG = Effective R-value of proposed new Above-Ground Foundation assembly (including all layers between inside air and outside air).

= Actual

R_ExistAG = Effective R-value value of existing Above-Ground Foundation assembly and any existing insulation.

= Minimum of R-5 for uninsulated assemblies[1748]

A_AG = Net area of Above-Ground Foundation being insulated (ft^2)

[1745] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1746] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1747] An estimate based on review of Madison Gas and Electric, Exterior Wall Insulation, R-value for no insulation in walls, and NREL's Building Energy Simulation Test for Existing Homes (BESTEST-EX).

[1748] An estimate based on review of Madison Gas and Electric, Exterior Wall Insulation, R-value for no insulation in walls, and NREL's Building Energy Simulation Test for Existing Homes (BESTEST-EX).

= Actual

R_NewBG = Effective R-value of proposed new Foundation Below Grade assembly (including all layers between inside air and outside ground).

= Actual

R_ExistBG = Effective R-value value of existing Foundation Below Grade assembly and any existing insulation.

NOTE: Added to the above R-values of Below Grade assemblies shall be the following deemed Average Earth R-values, which account for transmission of heat through direct contact with the earth outside the foundation. The Effective Ground Contact R-value varies as a function of the average depth below grade of the bottom of the foundation:[1749]

Depth Below Grade of Bottom of Foundation	Earth R-value	Average Earth R-value
0 feet	2.44 F-Ft^2-Hr/Btu	2.44 F-Ft^2-Hr/Btu
1 feet	4.50 F-Ft^2-Hr/Btu	3.47 F-Ft^2-Hr/Btu
2 feet	6.30 F-Ft^2-Hr/Btu	4.41 F-Ft^2-Hr/Btu
