5 feet	12.66 F-Ft^2-Hr/Btu	7.46 F-Ft^2-Hr/Btu
6 feet	14.49 F-Ft^2-Hr/Btu	8.46 F-Ft^2-Hr/Btu
7 feet	17.00 F-Ft^2-Hr/Btu	9.53 F-Ft^2-Hr/Btu
8 feet	20.00 F-Ft^2-Hr/Btu	10.69 F-Ft^2-Hr/Btu

A_BG = Net area of Foundation Below Grade being insulated (ft^2)

= Actual

$EFLH_{cooling}$ = Equivalent Full Load Hours for Cooling [hr] in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

$\Delta T_{FL,cooling}$ = Temperature difference [°F] during cooling season between design day outdoor air temperature (T_{DD}) and assumed 55°F base temperature

Climate Zone (City based upon)	$T_{DD,,cooling}$ [°F][1750]	$\Delta T_{FL,cooling}$ [°F]
1 (Rockford)	90.9	35.9
2 (Chicago)	91.3	36.3
3 (Springfield)	92.6	37.6
4 (Belleville)	95.2	40.2
5 (Marion)	94.4	39.4

1000 = Converts Btu to kBtu

[1749] Source: Illinois Statewide Technical Reference Manual V10.0, Volume 3 - Section 5.6.2 Basement Sidewall Insulation, Table on page 338 of 401.

[1750] Weather Station Data, 0.4% Cooling DB - 2021 ASHRAE Handbook, Fundamentals. The following weather stations were referenced: Climate Zone 1: Chicago Rockford Int'l, Climate Zone 2: Chicago O'Hare Int'l, Climate Zone 3: Abraham Lincoln Capital, Climate Zone 4: Scott AFB, Climate Zone 5: Cape Girardeau Regional.

ηCool = Efficiency of cooling equipment * distribution efficiency. Actual and assume 95% distribution efficiency for central cooling with ducts. If unknown assume:[1751]

Space Cooling Source	Deemed Cooling EER2	Deemed Cooling SEER2
No Cooling	N/A	N/A
Unknown Cooling Source	10.2	11.1

%Cool = Percent of building ***where wall or foundation insulation is to be installed*** that is cooled

= Actual %, if known, or, If actual % unknown, use following deemed values:

Is Space Being Insulated Cooled?	Deemed %Cool, if actual % is unknown
Yes	100%
No	0%

For example, for a elementary school building with unknown cooling equipment in Rockford with increase in wall insulation: R_ExistWall = 5.0; R_NewWall = 16.0; A_wall = 1,500; ηCool = 13.0; %Cool = 100%

ΔkWh_cooling = (1/5.0 - 1/16.0) * 1,500 * 834 * 35.9 / 1,000 / 11.0 * 100%
= 561 kWh

ΔkWh_heatingElectric = If electric heat (resistance or heat pump), reduction in annual electric heating due to wall and/or foundation insulation

= [(1/R_ExistWall - 1/R_NewWall) * A_wall + (1/R_ExistAG - 1/R_ NewAG) * A_AG + (1/R_ExistBG - 1/R_NewBG) * A_BG] * $EFLH_{heating}$ * $\Delta T_{FL,heating}$ / ηHeat / 3412 * %ElectricHeat

Where:

$EFLH_{heating}$ = Equivalent Full Load Hours for Heating [hr] in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

$\Delta T_{FL,heating}$ = Temperature difference [°F] during heating season between design day outdoor air temperature and assumed 55°F heating base temperature

Climate Zone (City based upon)	$T_{DD,heating}$ [°F][1752]	$\Delta T_{FL,heating}$ [°F]
1 (Rockford)	-5.4	60.4
2 (Chicago)	-1.0	56.0
3 (Springfield)	1.1	53.9
4 (Belleville)	7.2	47.8
5 (Marion)	10.1	44.9

[1751] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER and EER values converted to SEER2/EER2 by multiplying by 0.95 and multiplied by 0.95 distribution efficiency.
[1752] Weather Station Data, 96.6% Heating DB - 2021 ASHRAE Handbook, Fundamentals. The following weather stations were referenced: Climate Zone 1: Chicago Rockford Int'l, Climate Zone 2: Chicago O'Hare Int'l, Climate Zone 3: Abraham Lincoln Capital, Climate Zone 4: Scott AFB, Climate Zone 5: Cape Girardeau Regional.

ηHeat = Efficiency of heating system. Actual, or as deemed from table below

System Type	HSPF2 Estimate	ηHeat (Effective COP Estimate) (HSPF2/3.413)*0.95
Heat Pump	7.37[1753]	2.05
Resistance	N/A	1

3412 = Converts Btu to kWh

%ElectricHeat = Percent of building ***where wall or foundation insulation is to be installed*** that is electrically heated

= Actual %, if known, or, If actual % unknown, use following deemed values:

Is Space Being Insulated Electrically Heated?	Deemed %ElectricHeat, if actual % is unknown
Yes	100%
No	0%

For example, for a elementary school building with resistance heating in Rockford: R_ExistWall = 5.0; R_NewWall = 16.0; A_wall = 1,500; ηHeat = 1.0; %ElectricHeat = 100%

ΔkWh_heatingElec = (1/5.0 - 1/16.0) * 1,500 * 1,614 * 60.4 / 3,412 / 1.0 * 100%
= 5,893 kWh

ΔkWh_heatingGas = If gas *furnace* heat, kWh savings for reduction in combustion fan run time

= ΔTherms * F_e * 29.3

Where:

ΔTherms = Annual therms of gas space heating saved, as determined below

F_e = Furnace or boiler combustion fan energy consumption as a percentage of annual fuel consumption

= 7.7%[1754]

29.3 = conversion of therms to kWh (= 100,000 / 3412)

For example, if: ΔTherms = 251; F_e = 7.7%, then:

ΔkWh_heatingGas = 251 * 7.7% * 29.3

= 566 kWh

[1753] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note HSPF value converted to HSPF2 by multiplying by 0.85.

[1754] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh_cooling \ / \ EFLH_Cooling \ * \ CF$$

Where:

ΔkWh_cooling = Annual kWh saving in cooling energy use, as determined above

EFLH_cooling = Equivalent Full Load Hours for cooling in Existing Buildings are provided in section 4.4 HVAC End Use

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1755]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8% [1756]

For example, for a elementary school in Rockford with unknown cooling per above example: ΔkWh_cooling = 687; EFLH_Cooling = 1,020; CF = 0.478; then:

ΔkW = 561 / 834 * 0.478

= 0.32 kW

FOSSIL FUEL SAVINGS

If Natural Gas heating:

$$\Delta Therms = [(1/R_ExistWall - 1/R_NewWall) * A_wall + (1/R_ExistAG - 1/R_ NewAG) * A_AG + (1/R_ExistBG - 1/R_NewBG) * A_BG] * EFLH_{heating} * \Delta T_{FL,heating} / \eta Heat / 100{,}000 * \%GasHeat$$

Where:

ηHeat = Efficiency of heating system, including distribution losses.

= Actual, if unknown assume a value of 0.821.[1757]

%GasHeat = Percent of space being retrofitted with insulation that is heated using gas

= Actual %, if known, or, If actual % unknown, use following deemed values:

Is Space Being Insulated Heated with Gas?	Deemed %GasHeat, if actual % is unknown
Yes	100%
No	0%

Other variables as defined above.

[1755] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1756] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1757] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

For example, for a elementary school building in Rockford with unknown gas heat: R_ExistWall = 5.0; R_NewWall = 16.0; A_wall = 1,500; ηHeat = 0.8; %GasHeat = 100%; then

ΔTherms = (1/5.0 - 1/16.0) * 1500 * 1,614 * 60.4/ 0.8 /100,000 * 100%

= 251 therms

4.8.8 Commercial Secondary Windows

DESCRIPTION

Commercial Secondary Windows (CSW) are window units with one or more transparent panes in a frame that attach to the interior or exterior of existing windows without replacing the original glass or frame. Secondary windows are retrofitted to existing commercial windows to improve their overall thermal performance by adding a layer of glazing. CSWs have a non-disruptive installation and can improve windows to meet current IECC[1758] standards, resulting in heating and cooling energy savings.

Single-pane clear windows can increase the energy load through increased heat gain or heat loss, ultimately disrupting occupant comfort, and raising energy costs. Replacing windows can be costly, time-consuming, and disruptive to occupants, and hence it presents an opportunity of secondary window retrofits as a cost-effective energy efficiency measure.

A prescriptive methodology was developed to calculate energy savings associated with CSW retrofits in different commercial buildings across all Illinois climate zones through an energy modeling[1759] analysis. An AERC[1760] single-pane, metal-framed window was used as the baseline during the analysis and compared to a CSW retrofit meeting IECC 2021 standards for exterior fenestration assemblies. Heating and Cooling energy savings factors are derived from the energy modeling analysis for different building types and climate zones in Illinois and are utilized in the methodology section to calculate measure energy savings.

An external spreadsheet calculator[1761] has been developed to calculate energy savings associate with this measure based on building-specific inputs listed below.

- Building Types
- Hospital, Hotel, Multifamily, Office, Restaurant, Retail/Strip Mall and School
- Total Area of CSW Retrofit
- Heating System Fuel
- Gas or Electric
- Gas Heating System Efficiency
- Electric Heating System Efficiency
- Cooling System Efficiency
- Building Location Zip Code
    - Zip codes for the state of Illinois matching one of the following climate zones:
        - 1 – Rockford
        - 2– Chicago
        - 3– Springfield
        - 4– Belleville
        - 5 – Marion

The calculator incorporates heating and cooling energy savings factors for different building types and locations based on the energy modeling analysis performed on the DOE's Prototype Building Models[1762].

[1758] IECC 2021 – https://codes.iccsafe.org/content/IECC2021P2 based on current state code defined under https://www.energycodes.gov/status/states/illinois

[1759] Energy Modeling was Performed in EnergyPlus (E+), using the DOE's Office of Energy Efficiency & Renewable Energy (EERE) Prototype Building Models with different Illinois climate zones. Detailed information on energy modeling methodology, inputs and assumptions along with references are detailed in the calculator tool, see Energy Savings Calculator for CSW 05-15.xlsm

[1762] DOE EERE Prototype Buildings

DEFINITION OF EFFICIENT EQUIPMENT

Efficient equipment in this measure refers to commercial secondary windows (CSW) retrofitted in buildings. Retrofitted CSW assembly shall have minimum thermal properties as indicated in table below.

	Center of Glass U-Factor of the Overall window assembly with CSW Retrofit (Btu/hr °F ft2)	Solar Heat Gain Coefficient of the Overall window assembly with CSW Retrofit
Efficient CSW Unit[1763]	0.36	0.58

DEFINITION OF BASELINE EQUIPMENT

Baseline equipment refers to existing non-operable clear single-pane windows in existing buildings.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 30 years[1764].

DEEMED MEASURE COST

Total installation cost for retrofitting the Commercial Secondary Windows is the deemed measure cost. Total measure cost is assumed to be 32$ per square feet[1765] of CSW systems installed.

LOADSHAPE

Loadshape C03- Commercial Cooling

Loadshape C04 - Commercial Electric Heating

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (\Delta kWh_cooling + \Delta kWh_heatingElectric + \Delta kWh_heatingGas)$$

$$\Delta kWh_cooling = CSF * A * 3412.14 / (\eta Cool * 1000)$$

Where:

CSF[1768] = Cooling energy savings factor, kWh/ft^2/Btu/Wh

Building Types[1769]	Cooling Energy Savings Factor for Different Climate Zones and Building Types (kWh/ft^2/BTU/Wh)				
	1-Rockford	2-Chicago	3-Springfield	4-Belleville	5-Marion
Hospital	19.48	19.41	21.42	21.37	21.24
Hotel	16.07	16.21	18.61	18.09	18.61
Multifamily	14.46	14.54	16.96	16.54	17.32
Office	16.24	15.87	17.91	17.06	17.91
Restaurant	13.54	13.63	16.19	15.63	16.55
Retail/Strip Mall	16.54	16.80	18.92	17.98	18.82
School	16.51	16.12	18.31	17.09	17.79

A = Area of CSW system installed, ft^2

ηCool = Efficiency of cooling equipment (kBtu/kWh) * distribution efficiency. Actual or refer to IECC 2012[1770] minimum efficiency ratings based on the type of cooling equipment and assume 95% distribution efficiency for central cooling with ducts. If unknown assume:[1771]

Space Cooling Source	Deemed Cooling EER2	Deemed Cooling SEER2
No Cooling	N/A	N/A
Unknown Cooling Source	10.2	11.1

$$\Delta kWh_heatingElectric = HSF * A * 8.58 / \eta Heat$$

Where:

[1768] Cooling energy savings factor based on energy modeling on U.S. Department of Energy – Commercial prototype building models comparing window performance with CSW Retrofits and baseline single pane windows. Energy model inputs, results and assumptions will be externally attached for the Illinois Stakeholder Advisory Group – Technical Advisory Committee (TAC).
[1769] Building type classification should be based on definitions under Illinois Technical Reference Manual version 12, volume 1: overview and user guide, section 3.6. IL-TRM_Effective_010124_v12.0_Vol_1_Overview_09222023_FINAL_clean.pdf (ilsag.info).
For building types unknown, building type should be selected to closely resemble one of the building types listed in the table per interpretation of the program implementor based on actual building usage.
[1770] International Energy Efficiency Code 2012, chapter 4 Commercial Energy Efficiency, table c403.2.3(1) minimum efficiency requirements: electrically operated unitary air conditioners and condensing units.
https://codes.iccsafe.org/content/IECC2012/chapter-4-ce-commercial-energy-efficiency
[1771] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER and EER values converted to SEER2/EER2 by multiplying by 0.95 and multiplied by 0.95 distribution efficiency.

HSF[1772] = Heating energy savings factor, Therms/ft^2/Btu/Wh

= Refer to Fossil Fuel Savings section

8.58 = Factor to account for Therms to Wh and for Btu to kWh unit conversions

ηHeat = Efficiency of heating system * distribution efficiency

= Actual value (where new or where it is possible to measure or reasonably estimate) or refer to CFR 431 minimum efficiency ratings based on the type of heating equipment or refer to the table below if equipment type is unknown, and assume 95% distribution efficiency.

System Type	HSPF2 Estimate	ηHeat (Effective COP Estimate) (HSPF2/3.413)*0.95 (Distribution Efficiency)
Heat Pump	7.37[1773]	2.05
Resistance	N/A	1

ΔkWh_heatingGas = If gas furnace heat, kWh savings for reduction in fan run time

= ΔTherms * Fe * 29.3

Where:

Fe = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 7.7%[1774]

29.3 = kWh per therm

For Example, a hotel in Rockford with an all electric HVAC system installing 50 sqft of commercial secondary windows would save:

ΔkWh = ΔkWh Cooling + ΔkWh HeatingElectric + ΔkWh HeatingGas

ΔkWh Cooling = CSF * A * 3,412.14 / (ηCool * 1,000)

= 16.07 * 50 * 3412.14/(11.1 * 1000)

= 247.0 kWh

ΔkWh Heating Electric = HSF * A * 8.58 / ηHeat

= 0.94 * 50 * 8.58/2.05

= 196.7 kWh

ΔkWh = 247.0 + 196.7 + 0

= 443.7 kWh

[1772] Heating energy savings factor based on energy modeling on U.S. Department of Energy – Commercial prototype building models comparing window performance with CSW Retrofits and baseline single pane windows. Energy model inputs, results and assumptions will be externally attached for the Illinois Stakeholder Advisory Group – Technical Advisory Committee (TAC).

[1773] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note HSPF value converted to HSPF2 by multiplying by 0.85.

[1774] Fe is estimated using TRM models for the three most popular building types for programmable thermostats: low-rise office (10.2%), sit-down restaurant (8.6%), and retail–strip mall (4.4%). 7.7% reflects the average Fe of the three building types. See "Fan Energy Factor Example Calculation 2021-06-23.xlsx" for reference.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = (ΔkWh_cooling / EFLH_cooling) * CF

Where:

EFLHcooling = Equivalent full load hours of air conditioning in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%[1775]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8%[1776]

FOSSIL FUEL SAVINGS

ΔTherms = (HSF * A) / ηHeat

Where:

HSF[1777] = Heating energy savings factor, Therms/ft^2

Building Types[1778]	Heating Energy Savings Factor for Different Climate Zones and Building Types (Therms/ft^2)				
	1-Rockford	2-Chicago	3-Springfield	4-Belleville	5-Marion
Hospital	0.83	0.80	0.64	0.62	0.61
Hotel	0.94	0.89	0.77	0.71	0.69
Multifamily	1.03	0.99	0.88	0.79	0.76
Office	0.82	0.80	0.72	0.65	0.63
Restaurant	0.96	0.90	0.81	0.76	0.73
Retail/Strip Mall	0.90	0.84	0.76	0.72	0.69
School	0.85	0.83	0.75	0.69	0.66

ηHeat = Efficiency of heating system in Et or Ec where Et is the thermal efficiency and Ec is the combustion efficiency as defined in 10 CFR 431 * distribution efficiency

= Actual or if unknown, assume a value of 0.821.[1779]

[1775] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[1776] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1777] Heating energy savings factor based on energy modeling on U.S. Department of Energy – Commercial prototype building models comparing window performance with CSW Retrofits and baseline single pane windows. Energy model inputs, results and assumptions will be externally attached for the Illinois Stakeholder Advisory Group – Technical Advisory Committee (TAC).
[1778] Building type classification should be based on definitions under Illinois Technical Reference Manual version 12, volume 1: overview and user guide, section 3.6. IL-TRM_Effective_010124_v12.0_Vol_1_Overview_09222023_FINAL_clean.pdf (ilsag.info).
For building types unknown, building type should be selected to closely resemble one of the building types listed in the table based on the interpretation of the program implementor.
[1779] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Total heating capacity provided by 54% Furnace and 46% Boiler at 83.1% and 85.8% AFUE respectively, multiplied by estimate of distribution losses of 95%.

For example, a hotel in Rockford with a gas furnace installed before 2023 installing 50 sqft of Commercial Secondary Windows would save:

ΔkWh = ΔkWh Cooling + ΔkWh HeatingElectric + ΔkWh Heating Gas

ΔkWh HeatingGas = ΔTherms * Fe * 29.3

ΔTherms = (HSF * A) / ηHeat

= (0.94 * 50) / 0.821

= 57.2 Therms

ΔkWh Heating Gas = 57.2 * 7.7% * 29.3

= 129.0 kWh

ΔkWh = 234.3 + 0 + 129.0

= 363.3 kWh

4.8.9 Efficient Windows

DESCRIPTION

This measure describes savings realized by the installation of new windows that have better thermal insulating properties compared to either baseline or code requirements. For a comprehensive estimate of impacts, including the effects of solar gains, computer modeling is recommended.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient solution is a window assembly with a U-factor that is better than code and a Solar Heat Gain Coefficient (SHGC) that is at least equal to but not greater than code requirements. Windows are independently tested and certified according to the standards established by the National Fenestration Rating Council (NFRC). In addition to the NFRC, any NFRC-licensed independent certification and inspection agency can provide a certification. Though not a requirement for this measure, it is strongly recommended that the efficient window assembly is NFRC certified. The window must be installed in a commercial or industrial facility that is conditioned year-round (heating and cooling).

DEFINITION OF BASELINE EQUIPMENT

For new construction applications, the baseline equipment is a window with a U-factor and a Solar Heat Gain Coefficient (SHGC) that are equal to code requirements (IECC 2021). For retrofit applications, the baseline equipment is the U-factor of the existing window.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years.[1780]

DEEMED MEASURE COST

Actual installed costs should be used.

LOADSHAPE

Loadshape C03 – Commercial Cooling

Loadshape C04 – Commercial Electric Heating

Loadshape C05 – Commercial Electric Heating and Cooling

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%[1781]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8%[1782]

[1780] Consistent with window measure lives specified in the MidAmerican Energy Company Joint Assessment, February 2013.
[1781] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.
[1782] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Algorithm

CALCULATION OF ENERGY SAVINGS

The following calculations apply to a single window assembly. Note that the effects of a lower SHGC are not considered in this characterization. A lower SHGC does not necessarily equate to net savings due to the possible opposite effects it can have on heating and cooling loads. For optimum design and estimation of impacts from solar gain, a custom analysis should be performed that considers building site and orientation considerations.

ELECTRIC ENERGY SAVINGS

Electric Energy savings is calculated as the sum of energy savings when cooling the building and energy savings when heating the building.

$$\Delta kWh = \Delta kWh_{cooling} + \Delta kWh_{heating}$$

If the facility is mechanically cooled, the electric energy savings in annual cooling due to the added insulation is as follows:

$$\Delta kWh_{cooling} = \frac{\left(U_{base} - U_{eff}\right) \times A_{window} \times EFLH_{cooling} \times \Delta T_{FL,cooling}}{(1{,}000 \times \eta_{cooling})}$$

Where:

U_{base} = For Retrofit applications: U-factor of existing window (Btu/ft^2.°F.h).

= Actual; or if window type is known, use the associated value from the table below. If window type is unknown, use the "unknown" value from the table below.[1783]

Window Type	Climate Zone 5A	Climate Zone 4A
Fixed Fenestration – Metal Framing	0.488	0.510
Fixed Fenestration – Non-Metal Framing	0.421	0.460
Operable Fenestration – Metal Framing	0.511	0.533
Operable Fenestration – Non-Metal Framing	0.444	0.483
Unknown	0.466	0.497

= For New Construction applications: Code required U-factor (Btu/ft^2.°F.h).

= Dependent on climate zone and window type. If unknown, assume the most conservative value. See table below for IECC 2021 requirements.

Window Type	Climate Zone 5A	Climate Zone 4A
Fixed Fenestration	0.36	0.36
Operable Fenestration	0.45	0.45

U_{eff} = U-factor value of the efficient window assembly (Btu/ft^2.°F.h)

[1783] Table values result from a simple average of U-value requirements from the International Energy Conservation Code (IECC) 2000 – 2015 (6 versions). For the 2000 & 2003 codes, climate zones 12b,13b and 14b were used for zone 5, and 10b and 11b for zone 4 as these were updated in subsequent IECC versions. Also assumed 10-25% building glass surface for the 2000 & 2003 code. Does not include values for curtain walls, skylights, or entrance doors.

= Actual

A_{window} = The area of the window assembly [ft^2]

= Actual

$EFLH_{cooling}$ = Equivalent Full Load Hours for Cooling [hr] in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

$\Delta T_{FL,cooling}$ = Temperature difference [^oF] during cooling season between design day outdoor air temperature (TDD) and assumed 55^oF base temperature

Climate Zone (City based upon)	$TDD_{cooling}$ [°F][1784]	$\Delta T_{FL,cooling}$ [°F]
1 (Rockford)	90.9	35.9
2 (Chicago)	91.3	36.3
3 (Springfield)	92.6	37.6
4 (Belleville)	95.2	40.2
5 (Marion)	94.4	39.4

1,000 = Conversion from Btu to kBtu

η_cooling = Efficiency of cooling equipment (kBtu/kWh) * distribution efficiency. Actual (for new construction, use IECC 2021) and assume 95% distribution efficiency for central cooling with ducts. If unknown assume:[1785]

Space Cooling Source	Deemed Cooling EER2	Deemed Cooling SEER2
No Cooling	N/A	N/A
Unknown Cooling Source	10.2	11.1

If the building is heated with electric heat (resistance or heat pump), the electric energy saved in annual heating due to the added insulation is

$$\Delta kWh_{heating} = \frac{\left(U_{base} - U_{eff}\right) \times A_{window} \times EFLH_{heating} \times \Delta T_{FL,heating}}{(3{,}412 \times \eta_{heating})}$$

$EFLH_{heating}$ = Equivalent Full Load Hours for Heating [hr] in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

$\Delta T_{FL,heating}$ = Temperature difference [^oF] during heating season between design day outdoor air temperature and assumed 55^oF heating base temperature

Climate Zone (City based upon)	$TDD_{heating}$ [°F][1786]	$\Delta T_{FL,heating}$ [°F]
1 (Rockford)	-5.4	60.4

[1784] Weather Station Data, 0.4% Cooling DB - 2021 ASHRAE Handbook, Fundamentals. The following weather stations were referenced: Climate Zone 1: Chicago Rockford Int'l, Climate Zone 2: Chicago O'Hare Int'l, Climate Zone 3: Abraham Lincoln Capital, Climate Zone 4: Scott AFB, Climate Zone 5: Cape Girardeau Regional.

[1785] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note SEER and EER values converted to SEER2/EER2 by multiplying by 0.95 and multiplied by 0.95 distribution efficiency.

[1786] Weather Station Data, 96.6% Heating DB - 2021 ASHRAE Handbook, Fundamentals. The following weather stations were referenced: Climate Zone 1: Chicago Rockford Int'l, Climate Zone 2: Chicago O'Hare Int'l, Climate Zone 3: Abraham Lincoln Capital, Climate Zone 4: Scott AFB, Climate Zone 5: Cape Girardeau Regional.

Climate Zone (City based upon)	$TDD_{heating}$ [°F][1786]	$\Delta T_{FL,heating}$ [°F]
2 (Chicago)	-1.0	56.0
3 (Springfield)	1.1	53.9
4 (Belleville)	7.2	47.8
5 (Marion)	10.1	44.9

3,142 = Conversion from Btu to kWh.

$\eta_{heating}$ = Efficiency of heating equipment * Distribution Efficiency. Use actual efficiency and assume 95% distribution efficiency. If not available refer to default table below.

System Type	HSPF2 Estimate	ηHeat (Effective COP Estimate) (HSPF2/3.413)*0.95 (Distribution Efficiency)
Heat Pump	7.37[1787]	2.05
Resistance	N/A	1

For example, a new construction office in Chicago with an all electric HVAC system installing 50 sqft of commercial efficient windows with a U factor if 0.25 would save:

$\Delta kWh = \Delta kWh_{cooling} + \Delta kWh_{heating}$

$\Delta kWh_{cooling} = ((U_{base} - U_{eff}) * A_{window} * EFLH_{cooling} * \Delta T_{FL,cooling})/(1{,}000 * \eta_{cooling})$

$= ((0.36 - 0.25) * 50 * 1{,}790 * 36.3) / (1{,}000 * 15.2)$

$= 23.5$ kWh

$\Delta kWh_{heating} = ((U_{base} - U_{eff}) * A_{window} * EFLH_{heating} * \Delta T_{FL,heating})/(1{,}000 * \eta_{heating})$

$= ((0.36 - 0.25) * 50 * 2{,}625 * 56.0) / (3{,}142 * 2.04)$

$= 116.2$ kWh

$\Delta kWh = 23.5 + 116.2$

$= 149.6$ kWh

If the building is heated with a gas furnace, there will be some electric savings associated with the reduction in furnace run time.

$$\Delta kWh_{gasheating} = \Delta Therms \times Fe \times 29.3$$

Where:

ΔTherms = Gas savings calculated with equation below.

[1787] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Nonresidential Baseline Study Results", Oct 31 2024. Note HSPF value converted to HSPF2 by multiplying by 0.85.

Fe = Percentage of heating energy consumed by fans, assume 7.7%[1788]

29.3 = Conversion from therms to kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh_{cooling}}{EFLH_{cooling}} \times CF$$

Where:

$EFLH_{cooling}$ = Equivalent full load hours of air conditioning in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3%[1789]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Commercial cooling (average during peak period)

= 47.8%[1790]

FOSSIL FUEL SAVINGS

If building uses a gas heating system, the savings resulting from the efficient window is calculated with the following formula

$$\Delta Therms = \frac{\left(U_{base} - U_{eff}\right) \times A_{window} \times EFLH_{heating} \times \Delta T_{FL,heating}}{(100{,}000 \times \eta_{heating})}$$

Where:

U_{base} = For Retrofit applications: U-factor of existing window (Btu/ft^2.°F.h).

= Actual; or if window type is known, use the associated value from the table below. If window type is unknown, use the "unknown" value from the table below.[1791]

Window Type	Climate Zone 5A	Climate Zone 4A
Fixed Fenestration – Metal Framing	0.488	0.510
Fixed Fenestration – Non-Metal Framing	0.421	0.460
Operable Fenestration – Metal Framing	0.511	0.533
Operable Fenestration – Non-Metal Framing	0.444	0.483

[1788] Fe is estimated using TRM models for the three most popular building types for programmable thermostats: low-rise office (10.2%), sit-down restaurant (8.6%), and retail – strip mall (4.4%). 7.7% reflects the average Fe of the three building types. See "Fan Energy Factor Example Calculation 2021-06-23.xlsx" for reference.

[1789] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1790] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1791] Table values result from a simple average of U-value requirements from the International Energy Conservation Code (IECC) 2000 – 2015 (6 versions). For the 2000 & 2003 codes, climate zones 12b,13b and 14b were used for zone 5, and 10b and 11b for zone 4 as these were updated in subsequent IECC versions. Also assumed 10-25% building glass surface for the 2000 & 2003 code. Does not include values for curtain walls, skylights, or entrance doors.

Window Type	Climate Zone 5A	Climate Zone 4A
Unknown	0.466	0.497

= For New Construction applications: Code required U-factor (Btu/ft^2.°F.h).

= Dependent on climate zone and window type. If unknown, assume the most conservative value. See table below for IECC 2021 requirements.

Window Type	Climate Zone 5A	Climate Zone 4A
Fixed Fenestration	0.36	0.36
Operable Fenestration	0.45	0.45

U_{eff} = U-factor value of the efficient window assembly (Btu/ft2.°F.h)

= Actual.

A_{window} = The area of the window assembly [ft^2]

$EFLH_{heating}$ = Equivalent Full Load Hours for Heating [hr] in Existing Buildings or New Construction are provided in Section 4.4, HVAC end use

$\Delta T_{FL,heating}$ = Temperature difference [°F] during heating season between design day outdoor air temperature and assumed 55°F heating base temperature (same as above)

Climate Zone (City based upon)	$TDD_{heating}$ [°F][1792]	$\Delta T_{FL,heating}$ [°F]
1 (Rockford)	-5.4	60.4
2 (Chicago)	-1.0	56.0
3 (Springfield)	1.1	53.9
4 (Belleville)	7.2	47.8
5 (Marion)	10.1	44.9

100,000 = Conversion from BTUs to Therms

$\eta_{heating}$ = Efficiency of heating system * distribution efficiency. Use actual efficiency and assume 95% distribution efficiency. If not available, assume 0.821.[1793]

4.9. Miscellaneous End Use

4.9.1 Pump Optimization

DESCRIPTION

Pump improvements can be done to optimize the design and control of centrifugal water pumping systems, including water solutions with freeze protection up to 15% concentration by volume. Other fluid and gas pumps cannot use this measure calculation. The measurement of energy and demand savings for commercial and industrial applications will vary with the type of pumping technology, operating hours, efficiency, and existing and proposed controls. Depending on the specific application slowing the pump, trimming or replacing the impeller may be suitable options for improving pumping efficiency. Pumps up to 40 HP are allowed to use this energy savings calculation. Larger motors should use a custom calculation (which may result in larger savings that this measure would claim).

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is proven to be an optimized centrifugal pumping system meeting the applicable program efficiency requirements:

Pump balancing valves no more than 15% throttled

Balancing valves on at least one load 100% open.

DEFINITION OF BASELINE EQUIPMENT

In order for this characterization to apply, the baseline equipment is assumed to be the existing pumping system including existing controls and sequence of operations.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 8 years.[1794]

DEEMED MEASURE COST

The incremental capital cost for this measure can vary considerably depending upon the strategy employed to achieve the required efficiency levels and should be determined on a site-specific basis.

LOADSHAPE

Loadshape C14: Indust. 1-shift (8/5) (e.g., comp. air, lights)
Loadshape C15: Indust. 2-shift (16/5) (e.g., comp. air, lights)
Loadshape C16: Indust. 3-shift (24/5) (e.g., comp. air, lights)
Loadshape C17: Indust. 4-shift (24/7) (e.g., comp. air, lights)

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 38%.[1795]

[1794] SCE Pump Test Final Report (2009), Summit Blue Consulting, LLC. This value is a weighted average of estimates provided by program participants.

[1795] Summer Peak Coincidence Factor has been preserved from the "Technical Reference Manual" (TRM) for Ohio Senate Bill 221 Energy Efficiency and Conservation Program and 09-512-GE-UNC," October 15, 2009. This is likely a conservative estimate, but is recommended for further study (as stated in the OH State TRM, page 269).

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (HP_{motor} * 0.746 * LF / \eta_{motor}) * HOURS * ESF$$

Where:

HP_{motor} = Installed nameplate motor horsepower

= Actual

0.746 = Conversion factor from horse-power to kW (kW/hp)

LF / η_{motor} = Combined as a single factor since efficiency is a function of load

= 0.65 [1796]

Where:

LF = Load Factor; Ratio of the peak running load to the nameplate rating of the motor

η_{motor} = Motor efficiency at pump operating conditions

HOURS = Annual operating hours of the pump

= Actual

ESF = Energy Savings Factor; assume a value of 15%.[1797]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (HP_{motor} * 0.746 * (LF / \eta_{motor})) * (ESF) * CF$$

Where:

CF = Summer Coincident Peak Factor for measure

4.9.2 Computer Power Management Software

DESCRIPTION

This measure characterizes the savings achieved through controlling the power management settings of a desktop computer, monitor or laptop. This can be achieved one of two ways; either a centralized computer power management software is installed on a network of computers to monitor and record usage and manage the power management settings of all units (referred to as Centralized Software), or the settings are adjusted on each individual unit (referred to as Individual Settings).

DEFINITION OF EFFICIENT EQUIPMENT

For Centralized Software, the efficient equipment is defined by the requirements listed below:

- Allow centralized control and override of computer power management settings of workstations which include both a computer monitor and CPU (i.e., a desktop or laptop computer on a distributed network)
- Be able to control on/off/sleep states on both the CPU and monitor according to the Network Administrator-defined schedules and apply power management policies to network groups
- Have capability to allow networked workstations to be remotely wakened from power-saving mode (e.g. for system maintenance or power/setting adjustments)
- Have capability to detect and monitor power management performance and generate energy savings reports
- Have capability to produce system reports to confirm the inventory and performance of equipment on which the software is installed.

For Individual Settings, each desktop, monitor, or laptop requires power settings to be adjusted to appropriately place devices in a low-power standby, sleep or off mode after a predetermined period of inactivity (for example display sleep mode after 10 minutes of inactivity and computer sleep mode after 30 minutes).

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF BASELINE EQUIPMENT

Baseline is defined as a desktop computer, monitor or laptop without the power management settings enabled.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

For Centralized Software, the expected measure life is five years.[1798]

For Individual Settings, the expected measure life is two years.[1799]

DEEMED MEASURE COST

For Centralized Software, the deemed measure cost is $29 per networked computer, including labor.[1800]

For Individual Settings, the deemed measure cost is $10 per unit.[1801]

[1803] Northwest Regional Technical Forum Non-Res Network Computer Power Management , January 29, 2015. Analysis can be found in NonResNetCompPwrMgt_v4_1.xlsm. https://rtf.nwcouncil.org/measure/non-res-network-computer-power-management

Computer Power State	Efficient Duty Cycle	
	Computer	Monitor
Off	77%	57%
Sleep	2%	2%
Idle	13%	N/A
Active	3%	19%

PowerState = Power (W) consumption in each power state[1804]

Computer Power State	Power Draw (Watts)		
	Desktop Computer	Laptop Computer	Monitor
Unplugged	0.0	0.0	0.0
Off	0.9	0.5	0.23
Sleep	2.1	0.9	0.32
Idle	39.9	8.9	N/A
Active	72.2	60.0	14.43

For example: Computer Savings:

kWh savings = (UECCompBase -UECCompEff)

UECCompBase = 0 x 5% x 8,760+0.9 x 55% x 8,760+2.1 x 2% x 8,760+39.9 x 35% x 8,760+72.2 x 3% x 8,760=146.2kWh

UECCompEff = 0 x 5% x 8760+0.9 x 77% x 8,760+2.1 x 2% x 8,760+39.9 x 13% x 8,760+72.2 x 3% x 8,760=70.5kWh

Computer kWh savings = (146.2-70.5) = 75.7kWh

For example: Laptop Savings:

UECCompBase = 0 x 5% x 8,760+0.5 x 55% x 8,760 + 0.9 x 2% x 8,760+8.9 x 35% x 8,760+60.0x 3% x 8,760= 45.6 kWh

UECCompEff = 0 x 5% x 8,760+0.5 x 77% x 8,760+ 0.9 x 2% x 8,760+8.9 x 13% x 8,760+60.0 x 3% x 8,760 = 29.4 kWh

Laptop kWh savings = (45.6 – 29.4) = 16.2 kWh

For example: Monitor Savings (assuming CPMS is controlling 2 monitors):

Monitor kWh savings = (UECMonBase - UECMonEff)

UECMonBase = (2 x 0 x 22% x 8,760+2 x 0.23 x 50% x 8,760+2 x 0.32 x 2% x 8,760+2 x 14.43 x 26% x 8,760)/1,000=67.9kWh

UECMonEff = (2 x 0 x 22% x 8,760+2 x 0.23 x 57% x 8,760+2 x 0.32 x 2% x 8,760+2 x 14.43 x 19% x 8,760)/1,000=50.5kWh

Monitor kWh savings = (67.9-50.5) = 17.4kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh/8,760

[1804] Northwest Regional Technical Forum Non-Res Network Computer Power Management , January 29, 2015. Analysis can be found in NonResNetCompPwrMgt_v4_1.xlsm. https://rtf.nwcouncil.org/measure/non-res-network-computer-power-management

Computer peak kW savings	= 75.7/8760	= 0.009 kW
Laptop peak kW savings	= 16.2/8760	= 0.002 kW
Monitor (assuming CPMS is controlling 2 monitors) peak kW savings

4.9.3 Modulating Commercial Gas Clothes Dryer

DESCRIPTION

This measure relates to the installation of a two-stage modulating gas valve retrofit kit on a standard commercial non-modulating gas dryer. Commercial gas clothes dryers found in coin-operated laundromats or on-premise laundromats (hospitals, hotels, health clubs, etc.) traditionally have a single firing rate which is sized properly for highest heat required in initial drying stages but is oversized for later drying stages requiring lesser heat. This causes the burner to cycle on/off frequently, resulting in less efficient drying and wasted gas. Replacing the single stage gas valve with a two-stage gas valve allows the firing rate to adjust to the changing heat demand, thereby reducing overall gas consumption.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

A 30 to 250 pound capacity commercial gas dryer retrofitted with a two-stage modulating gas valve kit.

DEFINITION OF BASELINE EQUIPMENT

A 30 to 250 pound capacity commercial gas dryer with no modulating capabilities.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The deemed measure life for the retrofit kit is 10 years.[1806]

DEEMED MEASURE COST

The full retrofit cost is assumed to be $700, including the material cost for the basic modulating gas valve retrofit kit ($600) and the associated of labor for installation ($100).[1807]

FOSSIL FUEL SAVINGS

Note: Accurately estimating dryer energy consumption is complicated and challenging due to a variety of factors that influence cycle times and characteristics and ultimately drying energy requirements. Clothing loads can vary by weight, volume, fiber composition, physical structure, and initial water content, meaning that for any given cycle

[1806] Since this is a retrofit measure to an existing piece of equipment the measure life is less than the full life of the drier. Assumed to be 10 years as cost would be prohibitive for older machines that are likely to be need replacing soon.

[1807] Engineering judgement, based on observed costs during Nicor Gas pilot study. "Nicor Gas Emerging Technology Program, 1036: Commercial Dryer Modulation Retrofit Public Project Report." 2014.

drying energy requirements can differ. Additionally, dryer settings selected by the user as well as interactions with the site's HVAC systems are known to influence dryer performance. As better information becomes available, this characterization can be modified to allow for a more site-specific estimation of savings.

$$\Delta Therms = N_{Cycles} * SF$$

Where:

N_{Cycles} = Number of dryer cycles per year. Refer to the table below if this value is not directly available.

Application	Cycles per Year
Coin- Operated Laundromats[1808]	1,483
Multi-family Dryers[1809]	1,074
On-Premise Laundromats[1810]	3,607

SF = Savings factor

= 0.18 therms/cycle[1811]

If using default cycles the savings are as follows:

Application	ΔTherms
Coin- Operated Laundromats[1812]	267
Multi-family Dryers[1813]	193
On-Premise Laundromats[1814]	649

4.9.4 High Speed Clothes Washer

DESCRIPTION

This measure applies to the installation of clothes washers with extraction speeds of 200G or greater, which is significantly higher than traditional hard-mount washers. Standard washer extractors in laundromats operate at speeds of 70-80G[1815]. The high-speed extraction process in the wash cycle removes more water from each compared to standard washers, reducing operating time and gas consumption of clothes dryers. Heat exposure and mechanical action are also reduced, resulting in less linen wear.

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is assumed to be a clothes washer with an extraction speed of 200G or greater, installed in a commercial laundromat. This measure is only applicable for sites utilizing gas dryers. Sites using electric dryers are not eligible for participation.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be a clothes washer with an extraction speed of 100G or less, installed in a commercial laundromat.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure lifetime is assumed to be the typical lifetime of a commercial clothes washer: 7 years.[1816]

For early replacement measures it is assumed the existing unit would last another 2.3 years.[1817]

DEEMED MEASURE COST[1818]

The incremental cost for time of sale is $11.83/lb capacity.

The full cost of the high speed washer for early replacement applications is $201.10/lb capacity. The deferred replacement cost of the baseline unit is $189.27/lb capacity. This future cost should be discounted to present value using the real discount rate.

[1817] One-third of expected measure life.

[1818] Measure costs are based on data from a 2016 quote provided by a commercial washer distributor to Franklin Energy Services, adjusted for inflation.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

$$\Delta Therms = (Ncycles * Days * Capacity * RMC * h_e / \eta_{dryer} /100{,}000) * DryerUse * LF$$

Where:

Ncycles = Average number of washer cycles per day

= Use values from table below, depending on application

Application	Ncycles
Coin-operated Laundromats	4.3[1819]
Multifamily	3.4[1820]
Hotel/Motel/Hospital	10.4[1821]

Days = Days per year of commercial laundromat operation

= Actual, or if unknown, assume 360 days[1822]

Capacity = Clothes washer rated capacity (lb/cycle)[1823]

= Actual

RMC = Retained Moisture Content (%)[1824] reduction from replacing a low extraction speed washer

Washer Upgrade	RMC
100G to 200G	0.15[1825]
100G to 400G	0.25[1826]
200G to 400G	0.10[1827]

[1819] "2014-2015 State of the Self-Service Laundry Industry Report." Carlo Calma, April 13, 2015.

[1820] "Assessment of Water Savings for Commercial Washers: Report on the Monitoring and Assessment of Water Savings from the Coin-Operated Multi-Load Clothes Washers Voucher Initiative Program." San Diego County Water Authority October 2016.

[1821] "Laundry Planning Guide." EDRO, January 2015.

[1822] Based on professional judgement, assuming closed on holidays.

[1823] Clothes washer capacity is based on weight of dry clothing.

[1824] The EDRO "Laundry Planning Guide" describes moisture retention as "the ratio of retained moisture weight to clean dry textile weight." The pounds of water retained by clothing at the end of a wash cycle is calculated by multiplying Capacity (lbs of dry clothing per cycle) by RMC.

[1825] Using chart provided (Figure 1) and assuming a 50/50 cloth blend load of cotton and polyester, the retained moisture drops from approximately 65% to 50% when a 100 g washer is replaced with a 200 g washer. Chart from "Laundry Planning Guide." EDRO, January 2015. The Department of Energy test procedures for commercial clothes washers specifies, "…the use of energy test cloth consisting of a pure finished bleach cloth, made with a momie or granite weave, which is a blended fabric of 50-percent cotton and 50-percent polyester." – Energy Conservation Program: Energy Conservation Standards for Commercial Clothes Washers; Final Rule, Notice of Proposed Rulemaking, DOE, March 2014 (10 CFR Part 431).

[1826] Using chart provided (Figure 1) and assuming a 50/50 cloth blend load of cotton and polyester, retained moisture drops from approximately 65% to 40% when a 100 g washer is replaced with a 400 g washer.

[1827] Using chart provided (Figure 1) and assuming a 50/50 cloth blend load of cotton and polyester, retained moisture drops from approximately 50% to 40% when a 200 g washer is replaced with a 400 g washer.

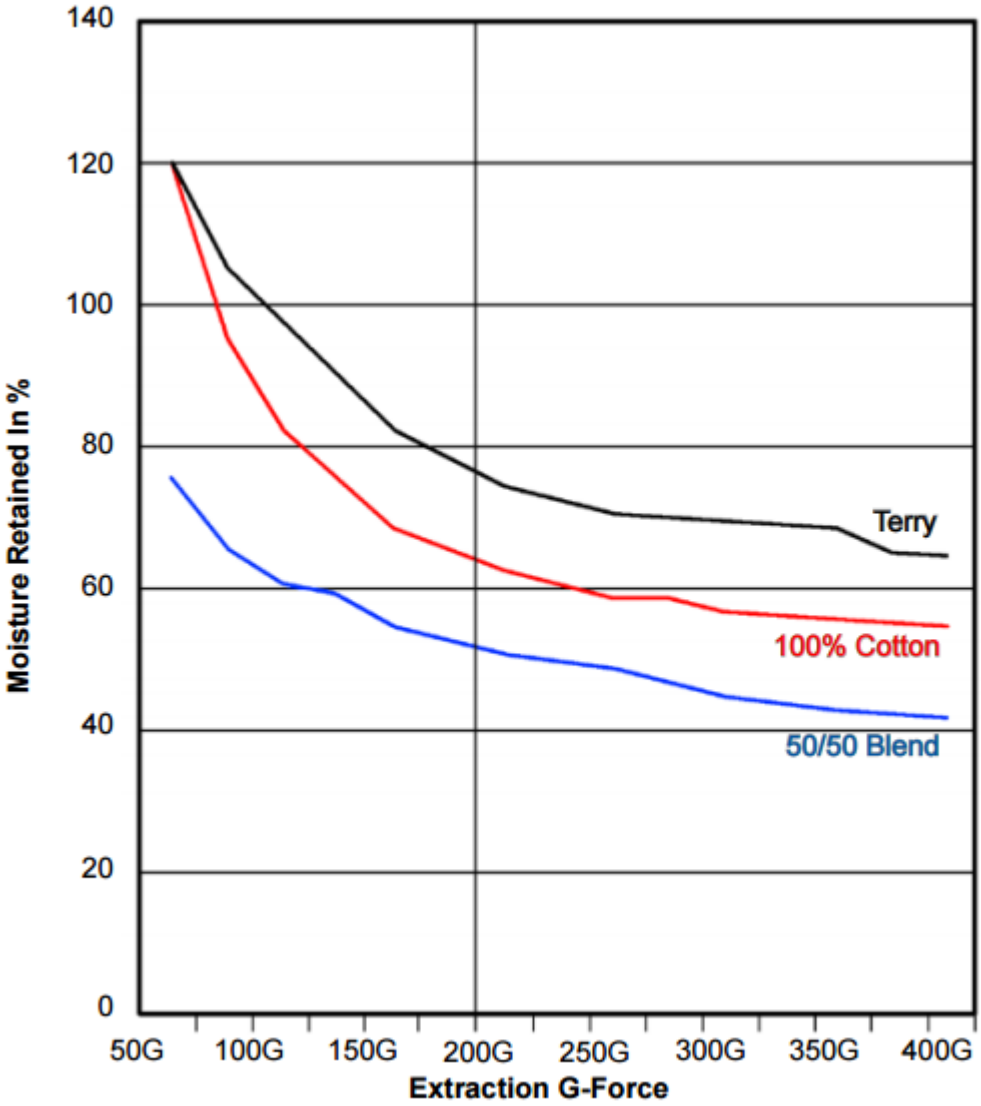

Figure 1

h_e = Heat required by a dryer to evaporate 1 lb of water

= Assume 1,200 Btu/lb[1828]

η_{dryer} = Efficiency of the clothes dryer

= Actual, or if unknown, assume 60%[1829]

100,000 = Converts Btus to therms

DryerUse = % of washer loads dried in the field

= Assume 91%[1830]

LF = Load Factor (%) to account for the pounds per washer load, as a percentage of rated capacity

[1828] "Laundry Planning Guide." EDRO, January 2015.

[1829] ACEEE (2010), "Are We Missing Energy Savings in Clothes Dryers?" Paul Bendt (Ecos), 2010

[1830] "Dryer Field Study." Northwest Energy Efficiency Alliance, November 20, 2014.

= Assume 66%[1831]

For example, a clothes washer with a 14 lb/cycle capacity and installed at a coin-operated laundromat, using default assumptions, would save:

ΔTherms = (Ncycles * Days * Capacity * RMC * h_e / η_{dryer} /100,000) * DryerUse * LF

= (4.3 * 360 * 14 * 0.25 * 1,200 / 0.60 /100,000) * 0.91 * 0.66

= 65 therms

4.9.5 ENERGY STAR Computers

DESCRIPTION

This measure estimates savings for a desktop computer with ENERGY STAR[1832] (ES) Version 9.0 rating, ES 9.0 with 80 PLUS Platinum PSUs, and ES 9.0 with 80 PLUS Titanium PSUs.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient product is a desktop with a rating of ENERGY STAR Version 9.0 rating, ES 9.0 with 80 PLUS Platinum PSUs, or ES 9.0 with 80 PLUS Titanium PSUs.

DEFINITION OF BASELINE EQUIPMENT

Non ENERGY STAR qualified equipment with standard efficiency power supply.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life of this measure is 4 years.[1833]

DEEMED MEASURE COST[1834]

The incremental cost for an 80 Plus Desktop PSU is $5.
The incremental cost for an ENERGY STAR desktop PSU is $20.

LOADSHAPE

C21 Commercial Office Equipment

COINCIDENCE FACTOR

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS[1835]

$$\Delta kWh = 8760/1000 * (((Watts_{Base,Off} * \%Time_{Off}) + (Watts_{Base,Sleep} * \%Time_{Sleep}) + (Watts_{Base,Long} * \%Time_{Long}) + (Watts_{Base,Short} * \%Time_{Short})) - ((Watts_{Eff,Off} * \%Time_{Off}) + (Watts_{Eff,Sleep} * \%Time_{Sleep}) + (Watts_{Eff,Long} * \%Time_{Long}) + (Watts_{Eff,Short} * \%Time_{Short})))$$

Where (see assumptions in table below):

8760/1000 = Converts W to kWh

$Watts_{Base,Off}$ = baseline equipment power in off mode

[1832] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[1833] Codes and Standards Enhancement (CASE) Initiative For PY 2013: Title 20 Standards Development. Analysis of Standards Proposal for Computers, August 6, 2013. Section 2.3 Design Life, Page 15.
[1834] NEEA Research Into Action, 80 PLUS Market Progress Evaluation Report #5, November 26, 2013. Page 24. This value is further confirmed by the Federal Energy Management Program, which states "FEMP has calculated that the required ENERGY STAR-qualified desktop computer saves money if priced no more than $55 (in 2021 dollars) above the less efficient model." The incremental cost of $20 sits as a comfortable average of cost-saving computer
[1835] ENERGY STAR Program Requirements for Computers - Eligibility Criteria v9.0, Section 3.5.2.v., Equation 1: TEC Calculation (ETEC) for Desktop, Integrated Desktop, and Notebook Computers, pg 16.

$\%Time_{Off}$ = typical percent of time a desktop, integrated desktop or notebook is in off mode during the year

$Watts_{Base,Sleep}$ = baseline equipment power in sleep mode

$\%Time_{Sleep}$ = typical percent time in sleep mode

$Watts_{Base,Long}$ = baseline equipment power in long idle mode

$\%Time_{Long}$ = typical percent time in long idle mode

$Watts_{Base,Short}$ = baseline equipment power in short idle mode

$\%Time_{Short}$ = typical percent time in short idle mode

$Watts_{Eff,Off}$ = efficient equipment power in off mode

$Watts_{Eff,Sleep}$ = efficient equipment power in sleep mode

$Watts_{Eff,Long}$ = efficient equipment power in long idle mode

$Watts_{Eff,Short}$ = efficient equipment power in short idle mode

Measure Annual Mode Time (%)	Off	Sleep	Long Idle	Short Idle
Duty cycle – Commercial Desktop[1836]	15%	45%	10%	30%

Measure Watt Draw in Mode (Watts)	Off	Sleep	Long Idle	Short Idle
Baseline[1837]	0.88	2.1	26.5	27.9
ES 9.0 Desktops[1838]	0.53	1.72	9.06	14.79
ES 9.0 Desktops w/ 80 PLUS Platinum PSUs[1839]	0.50	1.50	8.5	13.8
ES 9.0 Desktops w/ 80 PLUS Titanium PSUs[1840]	0.50	1.50	8.3	13.5

Calculated energy consumption in each mode, and savings provided below:

Measure TEC by Mode - Commercial	Off	Sleep	Long Idle	Short Idle	TEC (kWh/yr)	Savings (kWh/yr)
Baseline	1.2	8.3	23.2	73.3	106.0	N/A
ES 9.0 Desktops	0.7	6.8	7.9	38.9	54.3	51.7
ES 9.0 Desktops w/ 80 PLUS Platinum PSUs	0.7	5.9	7.4	36.3	50.2	55.7

[1836] ENERGY STAR Program Requirements for Computers - Eligibility Criteria v9.0, Section 3.5.2.v., Table 4: Mode Weightings for Desktops and Integrated Desktop Computers, pg 16.

MEASURE CODE: CI-MSC-COMP-V04-260101

REVIEW DEADLINE: 1/1/2027

[1841] It assumed that computers will not be off during peak period, and that the weighting of sleep, long idle and short idle during peak hours is consistent with the whole year. Wattage assumptions are weighted accordingly and coincidence factor is thus assumed to be 1.0 – see "ENERGY STAR Computers Analysis_2020_Revised.xlsx" for calculation.

4.9.6 Advanced Power Strip – Tier 1 Commercial

DESCRIPTION

This measure relates to Advanced Power Strips – Tier 1 which are multi-plug power strips with the ability to automatically disconnect specific connected loads depending upon the power draw of a control load, also plugged into the strip. Power is disconnected from the switched (controlled) outlets when the control load power draw is reduced below a certain adjustable threshold, thus turning off the appliances plugged into the switched outlets. By disconnecting, the standby load of the controlled devices, the overall load of a centralized group of equipment (e.g. a desk workstation) can be reduced. In a commercial office space, savings generally occur during off-hours, when connected equipment continues to consume electricity while in standby mode or when off. Uncontrolled outlets are also provided that are not affected by the control device and so are always providing power to any device plugged into it.

This measure was developed to be applicable to the following program types: DI, Kits.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is an advanced power strip with a load-sensing master plug and at least two controlled plugs.

DEFINITION OF BASELINE EQUIPMENT

The assumed baseline is a standard power strip with surge protection that does not control connected loads.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of the advanced power strip is 7 years.[1842]

DEEMED MEASURE COST

For direct install the actual full equipment and installation cost (including labor) and for kits the actual full equipment cost should be used.

Equipment cost if unknown[1843]:

Baseline Cost	Efficient Cost	Incremental Equipment Cost
$20	$30	$10

LOADSHAPE

Loadshape C47 – Standby Losses – Commercial Office[1844]

COINCIDENCE FACTOR

N/A due to no savings attributable to standby losses between 1 and 5 PM.

[1842] This is a consistent assumption with 5.2.2 Advanced Power Strip – Tier 2.

[1843] Price survey performed by Illume Advising LLC for IL TRM workpaper, see "Current Surge Protector Costs and Comparison 7-2016" spreadsheet.

[1844] Loadshapes were calculated from empirical studies and compared to the existing loadshape in Volume 1, Table 3.5. The studies were:
Acker, Brad *et. al,* "Office Space Plug Load Profiles and Energy Saving Interventions," 2012 ACEEE Summer Study on Energy Efficiency in Buildings.
Sheppy, M. *et al*, "Reducing Plug Loads in Office Spaces" Hawaii and Guam Energy Improvement Technology Demonstration Project, NREL/NAVFAC (January 2014).

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

ΔkWh[1845] = $((kW_{wkday} * (hrs_{wkday} - hrs_{wkday\text{-}open})) + (kW_{wkend} * (hrs_{wkend} - hrs_{wkend\text{-}open}))) * weeks/year * ISR$

Where:

kW_{wkday} = Standby power consumption of connected electronics on weekday off-hours. If unknown, assume 0.0315 kW.

kW_{wkend} = Standby power consumption of connected electronics on weekend off-hours. If unknown, assume 0.00617 kW.

hrs_{wkday} = total hours during the work week (Monday 7:30 AM to Friday 5:30 PM)

= 106

hrs_{wkend} = total hours during the weekend (Friday 5:30 PM to Monday 7:30 AM)

= 62

$hrs_{wkday\text{-}open}$ = hours the office is open during the work week. If unknown, assume 48 hours[1846].

$hrs_{wkend\text{-}open}$ = hours the office is open during the weekend. If unknown, assume 0 hours.

weeks/year = number of weeks per year

= 52.2

ISR = In Service Rate

= Assume 0.969 for commercial Direct Install application[1847], or 0.71 for kit distribution and midstream programs[1848].

For example, an office open 9 hours per day (45 hours per week) on weekdays and 4 hours on Saturday:

$\Delta kWh = ((0.0315 * (106 - 45)) + (0.00617 * (62 - 4))) * 52.2 * 0.969$

= 115 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A due to no savings attributable to standby losses between 1 and 5 PM.

FOSSIL FUEL SAVINGS

N/A

[1845] Savings algorithm reconstructed from weekday and weekend savings information in Acker, Brad *et. al,* "Office Space Plug Load Profiles and Energy Saving Interventions," 2012 ACEEE Summer Study on Energy Efficiency in Buildings, and verified against savings in Acker *et. al* and savings in: BPA, "Smart Power Strip Energy Savings Evaluation: Ross Complex," (2011). Office stations are assumed to have zero or minimal standy losses during normal operating hours. Method shown in "Commercial Tier 1 APS Calculations – IL TRM.xlsx".

[1846] Unknown hours are based on a Guidehouse review of open hours for 487 participants in similar measure.

[1847] Based upon review of the PY2 and PY3 ComEd Direct Install Residential program surveys. This value could be modified based upon commercial application evaluation.

[1848] Based on survey data collected from ComEd 2018 and 2019 Small Business Kits Program. The 2018 ISR was 0.592 and the 2019 ISR was 0.835, the average being 0.71.

4.9.7 High Efficiency Transformer

DESCRIPTION

Distribution transformers are used in commercial and industrial applications to step down power from distribution voltage to be used in HVAC or process loads (220V or 480V) or to serve plug loads (120V).

Distribution transformers that are more efficient than the required minimum federal standard efficiency qualify for this measure. If there is no specific standard efficiency requirement, the transformer does not qualify (because we cannot define a reasonable baseline). For example, although the federal standards increased the minimum required efficiency in 2016, most transformers with a NEMA premium or CEE Tier 2 rating will still achieve energy conservation. Standards are defined for low-voltage dry-type distribution transformers (up to 333kVA single-phase and 1000kVA 3-phase), liquid-immersed distribution transformers (up to 833kVA single-phase and 2500kVA 3-phase), and medium-voltage dry-type distribution transformers (up to 833kVA single-phase and 2500kVA 3-phase).

This measure was developed to be applicable to the following program types: TOS, NC.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Any transformer that is more efficient than the federal minimum standard. This includes CEE Tier II (single or three phase) and most NEMA premium efficiency rated products.

DEFINITION OF BASELINE EQUIPMENT

A transformer that meets the minimum federal efficiency requirement should be used as the baseline to calculate savings. Standards are developed by the Department of Energy and published in the Federal Register 10CFR 431.[1849]

The efficiency of a low-voltage dry-type, and liquid-immersed distribution transformer manufactured on or after January 1, 2016, shall be no less than that required for their kVA rating in the tables below. Distribution transformers with kVA ratings not appearing in the table shall have their minimum efficiency level determined by linear interpolation of the kVA and efficiency values immediately above and below that kVA rating.

(a) ***Low-Voltage Dry-Type Distribution Transformers.***

Single-phase		Three-phase	
kVA	Efficiency (%)	kVA	Efficiency (%)
15	97.70	15	97.89

833	99.31	99.23	99.20	1500	99.37	99.30	99.21
				2000	99.43	99.36	99.28
				2500	99.47	99.41	99.33

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

30 years[1850]

DEEMED MEASURE COST

Actual incremental costs should be used.

LOADSHAPE

Use custom loadshape based on application; default is Loadshape C67 (Ameren) or C68 (ComEd), which represent overall utility system loads.

COINCIDENCE FACTOR

Coincidence Factor for distribution transformers is 1.0 by definition. By including the load factor in the demand savings calculation, the load profile is accounted for.

Algorithm

CALCULATION OF ENERGY SAVINGS

Savings are determined by metering equipment

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = Losses_{base} - Losses_{EE}$$

Where:

$$Losses_{base} = \text{PowerRating} * \text{LF} * \text{PF} * \left(\frac{1}{EFF_{base}} - 1\right) * 8766$$

$$Losses_{EE} = \text{PowerRating} * \text{LF} * \text{PF} * \left(\frac{1}{EFF_{EE}} - 1\right) * 8766$$

PowerRating = kVA rating of the transformer (in units of kVA)

EFF_{base} = baseline total efficiency rating of federal minimum standard transformer (refer to baseline tables above based on kVA, voltage, and type of transformer)

EFF_{EE} = actual total efficiency rating of the transformer as calculated by the appropriate DOE test method.[1851]

LF = Load Factor for the transformer. Ratio of average transformer load to peak load rating over a period of one year. Use actual load factor for the network segment served based on historical data. If unknown, assume 15.9% for commercial and industrial loads.[1852]

PF = Power Factor for the load being served by the transformer. Ratio of real power to apparent power supplied to the transformer. Use actual power factor for the network segment served. If unknown, use 1.0 (unity) by default.[1853]

[1850] US DOE lists lifetime at 32 years. For consistency with efficiency measure evaluated lifetimes, 30 years is the recommended maximum deemed lifetime. US Department of Energy, "Energy Conservation Program: Energy Conservation Standards for Distribution Transformers; Final Rule", 10 CFR Part 431, Published April 18, 2013, Effective as of January 1, 2016.

[1851] Energy Conservation Program: Test Procedures for Distribution Transformers; Final Rule. Effective May 30, 2006.

[1852] "Transformers Efficiency, Unwinding the Technical Potential" Cadmus Group, 1999. Based on the RMS average loading from 89 low-voltage transformers across 43 buildings of a variety of sectors.

4.9.8 High Frequency Battery Chargers

DESCRIPTION

This measure applies to industrial high frequency battery chargers, used for industrial equipment such as fork lifts, replacing existing SCR (silicon controlled rectifier) or ferroresonant charging technology. High frequency battery chargers have a greater system efficiency.

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

High frequency battery charger systems with minimum Power Conversion Efficiency of 90% and a minimum 8-hour shift operation five days per week.

DEFINITION OF BASELINE EQUIPMENT

SCR or ferroresonant battery charger systems with minimum 8-hour shift operation five days per week.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

15 years[1854]

DEEMED MEASURE COST

The deemed incremental measure cost is $813.[1855]

LOADSHAPE

Loadshape C14 - Indust. 1-shift (8/5) (e.g., comp. air, lights)
Loadshape C15 - Indust. 2-shift (16/5) (e.g., comp. air, lights)
Loadshape C16 - Indust. 3-shift (24/5) (e.g., comp. air, lights)
Loadshape C17 - Indust. 4-shift (24/7) (e.g., comp. air, lights)

COINCIDENCE FACTOR

The coincidence factor is assumed to be 0.0 for 1 and 2-shift operation and 1.0 for 3 and 4-shift operation.[1856]

Algorithm

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (CAP * DOD) * CHG * (CR_B / PC_B - CR_{EE} / PC_{EE})$$

Where:

CAP = Capacity of Battery

= Use actual battery capacity, otherwise use a default value of 35 kWh[1857]

DOD = Depth of Discharge

= Use actual depth of discharge, otherwise use a default value of 80%.[1858]

CHG = Number of Charges per year

= Use actual number of annual charges, if unknown use values below based on the type of operations[1859]

Standard Operations	Number of Charges per year
1-shift (8 hrs/day – 5 days/week)	520
2-shift (16 hrs/day – 5 days/week)	1040
3-shift (24 hrs/day – 5 days/week)	1560
4-shift (24 hrs/day – 7 days/week)	2184

CR_B = Baseline Charge Return Factor

= Actual existing (early replacement) or if unknown assume 1.1613[1860]

PC_B = Baseline Power Conversion Efficiency

= Actual existing (early replacement) or if unknown assume 0.85[1861]

CR_{EE} = Efficient Charge Return Factor

= Actual or 1.1500[1862] if unknown

PC_{EE} = Efficient Power Conversion Efficiency

= Actual or 0.92[1863] if unknown

Default savings using defaults provided above are provided below:

Standard Operations	ΔkWh
1-shift (8 hrs/day – 5 days/week)	1,692
2-shift (16 hrs/day – 5 days/week)	3,383
3-shift (24 hrs/day – 7 days/week)	5,075
4-shift (24 hrs/day – 7 days/week)	7,104

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (PF_{EE} * PC_{EE} - PF_B * PC_B) * Volts_{DC} * Amps_{DC} / 1000 * CF$$

Where:

PF_B = Power factor of baseline charger

= Actual existing (early replacement) or if unknown assume 0.8600[1864]

PF_{EE} = Power factor of high frequency charger

4.9.9 Commercial Clothes Dryer Moisture Sensor

DESCRIPTION

This measure applies to moisture sensing controllers installed on new or existing commercial natural gas clothes dryers controlled electronically. Moisture controllers detect when the load is dry, which will stop the cycle from consuming additional energy. Some new commercial dryers utilize moisture sensors, but the majority of older dryers, as well as many new models, still do not utilize moisture sensors. In a commercial dyer, when a load is drying, the heat will run completely on in the early stages. Then, it begins to cycle on and off more frequently as the load becomes drier. Traditional moisture sensors use a conductivity strip in the dryer drum. The wet load will contact the strip that completes the circuit. When the load is dry, the circuit is shorted that completes the drying cycle. Instead, this technology is a "plug and play" retrofit controller that uses patent-pending software to determine when the load is dry. When the load is dry, it overrides the existing controls to end the cycle, which shuts the drying cycle. This measure does not apply to mechanical timer dryers or to dryers with modulating valves installed.

Natural gas energy savings will be achieved by reduced drying times and correspondingly reduced natural gas consumption. Electric savings will also be achieved by reduced operating times.

This measure was developed to be applicable to following facility types:

- Hotel/Motel
- Miscellaneous - Fitness and Recreational Sports Centers
- Hospital
- Assisted Living Facilities
- Miscellaneous - Dry cleaning
- Multifamily

Moisture sensing controller retrofits could create significant energy savings opportunities at other larger facility types with on-premise laundry operations (such as correctional facilities, universities, and staff laundries); however, the results included in this analysis are based heavily on past project data for the applicable facility types listed above and may not apply to facilities outside of this list due to variances in number of loads and average pound (lbs.) capacity per project site. Projects at these facilities should continue to be evaluated through custom programs and the applicable facility types and the resulting analysis should be updated based on new information.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

A retrofit moisture controlling technology is added to new or existing commercial natural gas clothes dryers. Existing facilities must be able to confirm that they do not have moisture sensors (conductive strip type) or modulating gas valves installed on clothes dryers already before proceeding with the installation of this technology.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a conventional natural gas clothes dryer without a moisture sensor or a modulating gas valve installed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The equipment effective useful life (EUL) is 10 years.[1870]

[1870] Since this is a retrofit measure to an existing piece of equipment the measure life is less than the full life of the drier. Assumed to be 10 years as cost would be prohibitive for older machines that are likely to need replacing soon.

DEEMED MEASURE COST

The full retrofit cost is assumed to be $600, including the material cost for the basic moisture control retrofit ($500) and the associated labor for installation ($100).[1871]

LOADSHAPE

Loadshape C55; Commercial Clothes Washer

COINCIDENCE FACTOR

The coincidence factor for this measure is dependent on the application:

Application	Coincidence Factor[1872]
Multi-family Dryers	0.15
On-Premise Laundromats	0.52

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Electric energy savings are per retrofitted dryer.

$\Delta kWh = N_{Cycles} * SF$

Where:

N_{Cycles} = Number of dryer cycles per year. Refer to the table below if this value is not directly available from the facility.

Application	Cycles per Dryer Per Year
Multi-family Dryers[1873]	1,074
On-Premise Laundromats[1874]	3,607

SF = Savings factor

= 0.16 kWh/cycle[1875]

If using default cycles the savings are as follows:

Application	ΔkWh per Dryer
Multi-family Dryers	171.8
On-Premise Laundromats	577.1

[1871] Based on Gas Technology Institute's analysis of cost data from "Nicor Gas Emerging Technology Program, 1069: Moisture Sensor Retrofit, Comprehensive Pilot Assessment Report," May 1, 2017.

[1872] In the absence of loadshape information for commercial applications, this is estimated by adjusting the residential coincidence factor proportionately by the relative number of loads (264 for residential and as described in this measure for commercial applications).

REVIEW DEADLINE: 1/1/2027

4.9.10 Efficient Thermal Oxidizers

DESCRIPTION

Thermal oxidizers are used to destroy volatile organic compounds (VOCs) from process exhausts, before emitting the treated air to the environment. VOC emissions are precursors to the formation of ground-level ozone pollution, and its control is mandated by the U.S. EPA. Some VOC constituents are individually toxic and require efficient destruction. Some waste streams have high enough concentrations to present an explosion hazard. Other waste streams merely present nuisance odors that need to be mitigated.

A facility may be required to utilize a thermal oxidizer by a state regulatory agency air quality permit. Some permits may require a VOC destruction efficiency that must be demonstrated with periodic emissions testing. Other permits merely require maintaining an oxidizer chamber temperature. A facility may also choose to utilize a thermal oxidizer for other purposes (nuisance odors) without a regulatory requirement.

The Efficient Thermal Oxidizer measure seeks to evaluate fossil fuel savings from utilizing more efficient means for VOC destruction with the use of a recuperative or regenerative thermal oxidizer. The heat recovery (either recuperative or regenerative) is used to pre-heat the inlet process air stream. This primary heat recovery is used within the thermal oxidizer process and the only heat recovery that is covered in this measure protocol. Fossil fuel savings will result from reduced burner firing. There is a "secondary" form of heat recovery that recovers heat from the combustion exhaust stack for other purposes like space heating, DHW heating, etc.

DEFINITION OF EFFICIENT EQUIPMENT

Two thermal oxidizer technologies can be considered as efficient equipment: recuperative and regenerative.

Recuperative Thermal Oxidizer

In a recuperative thermal oxidizer, the exhaust air stream is sent through a heat exchanger to indirectly pre-heat the inlet air stream coming from the process. The heat exchanger efficiency for a recuperator is typically 50-70%.[1879] The chamber temperature is typically 1,400°F to 1,500°F.

Regenerative Thermal Oxidizer

A regenerative thermal oxidizer utilizes a two-chamber ceramic bed as its heat exchanger system. The exhaust air passes through one bed, imparting its heat onto the ceramic media, while the intake air passes through the other bed, capturing the waste heat from the previous cycle. The flow reverses every few minutes so that the intake bed becomes the exhausted bed and vice versa. The heat exchanger efficiency of a regenerative system is much higher than a recuperative system. These efficiencies can reach 85% to 97%.[1880] However, the ceramic media needs to be periodically cleaned or replaced. The chamber temperatures in regenerative thermal oxidizers are typically 1,500°F to 1,600°F (depending on VOC requirements).

DEFINITION OF BASELINE EQUIPMENT

Depending on the facility process, there may be two baseline selection options: incinerator or recuperator.

The baseline thermal oxidizer with no heat recovery is referred to as an incinerator. This baseline is recommended for selection if it currently exists on site or in new construction when there is a specific process that cannot practically utilize a recuperator due to VOCs coating or clogging the heat exchanger. This system employs a burner to provide direct fire to a process exhaust air stream. Typical operative temperatures are 1,400°F to 2,200°F. The advantage of an afterburner is a quick startup and shutdown time that is ready on demand. The equipment cost is lower than the efficient equipment, but the fuel consumption is much higher.

In all other cases (existing equipment is recuperative or new construction/ expansion of manufacturing process), a recuperative thermal oxidizer is recommended as the appropriate baseline.

[1879] Presentation on the "Operating Cost Reduction Strategies for Oxidizers", presented by Rich Grzanka, during the Chem Show Technology Exposition on October 31, 2007.
[1880] Ibid.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected useful life of any thermal oxidizer system is assumed to 20 years.[1881]

DEEMED MEASURE COST

The cost of any thermal oxidizer is dependent on various variables such as air flow capacity, destruction efficiency, heat exchanger efficiency, etc.[1882] Shown below is an example of a system for 20,000 cfm.

Recuperative thermal oxidizer costs, based on their heat recovery efficiency, are detailed in the table below.

Heat Recovery Efficiency	Equipment Cost
0%	$106,042
35%	$174,193
50%	$203,801
70%	$253,801
Average	$184,317

A regenerative thermal oxidizer at 95% heat recovery has a deemed cost of $546,000.

Incinerator cost is treated as 0% heat recovery in the recuperative cost summary table above and has a deemed cost of $106,042.

LOADSHAPE

N/A

COINCIDENCE FACTOR

N/A

Algorithm

CALCULATION OF ENERGY SAVINGS

Energy savings from thermally efficient equipment are entirely fossil fuel related. There are no electricity savings nor peak demand savings, as the blower fans and valve actuators are assumed to operate the same in all conditions.

ELECTRIC ENERGY SAVINGS

N/A

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

ΔTherms = ((Baseline QT Air Pollution Control Device - Proposed QT Air Pollution Control Device) x Hours) / LHV

Where:

LHV = Latent Heat of Vaporization

= If the post is regenerative thermal oxidizer, LHV = 0.953.

= If the post is recuperative thermal oxidizer, LHV = 1.

[1881] EPA Air Pollution Control Cost Manual, Chapter 2, November 2017. The system capital recovery cost is based on an estimated 20-year equipment life. This estimate of oxidizer equipment life is consistent with information available to EPA and is consistent with statements from large vendors for incinerators and oxidizers.

[1882] U.S. Environmental Protection Agency, Incinerators and Oxidizers, Chapter 2, November 2017.

Regenerative or Recuperative: A baseline or proposed regenerative or recuperative air pollution control device can each be modeled in the following heat balance equation:[1883]

Q_T (btuh) = $Q_I + Q_{CC} + Q_{RL} – Q_{VOC}$

Incinerator: A baseline incinerator air pollution control device can be modeled as the following heat balance equation:

Q_T (btuh) = $Q_I + Q_{CC} + Q_{RL}$

Where:

Q_T = Total Energy Input

Q_I = Energy (btuh) used to raise the temperature of process air (F_I)

Q_{CC} = Heat (btuh) used to raise the temperature of combustion air (F_{CC})

Q_{RL} = Radiation heat loss (btuh) from RTO

Q_{VOC} = Heat release (btuh) provided by VOC combustion

Hours = Annual hours per year that oxidizer is used

Where:

$Q_I = F_I * 1.08 * (T_O – T_I)$

T_O = Average stack outlet temperature (°F) (actual trended average or use efficiency equation below to solve for T_O under assumed conditions)

T_O = $T_C - (N * (T_C - T_I) * F_I / (F_I + F_{CC})$

T_C = Combustion chamber temperature (°F), trended or design value provided by the manufacturer

N = Thermal Efficiency of Heat Exchanger

Thermal Oxidizer	Efficiency
Regenerative	97%
Recuperative	70%
Incinerator	0%

T_I = Inlet air temperature (°F), this is the temperature of the air coming from the process

F_I = Process air flow (cfm), actual loading or use maximum design value

1.08 = Conversion Factor

= 60 (min/hr) * 0.07489 (lb/ft^3, density air at standard conditions) * 0.2404 btu/°F-lb, (specific heat of air), where 0.2404 is average heat capacity of intake air

Where:

$Q_{CC} = F_{CC} * 1.08 * (T_O – T_A)$

F_{CC} = Additional combustion air flow (cfm) at provided F_I value

= If unknown, assume 3% of design value[1884]

T_O = Average outlet temperature (°F) (same as above)

T_A = Combustion intake air temperature (°F)

[1883] ICAC Guidance Method for Estimation of Gas Consumption in a Regenerative Thermal Oxidizer (RTO), July 2002.
[1884] Ibid.

= Indoor: Actual, or assume 70 °F year-round

= Outdoor: Actual annual average found near the facility, or assume TMY3 annual averages:

Region / Area	Average Outdoor Air Temperature (°F)
Chicago O'Hare	50.0
Chicago Midway	52.5
Rockford Airport	47.6

Where:

Q_{RL} = SA * HLF

SA = Surface Area (ft^2) (provided by the manufacturer or rough measurements taken)

HLF = Assume a heat loss factor of 240 btuh/ft^2 if installed outdoors; otherwise, 0 btuh/ft^2 for indoor installation since the waste heat provides space heating and offset gas-fired space heating equipment

Where:

Q_{VOC} = VOC * HC * (%Dest / 100)

VOC = Average lbs/hr from process to oxidizer

HC = btu/lb, weighted average for the heat of combustion of VOCS

= Site-specific, lookup table

%Dest = Destruction efficiency of VOCs provided by the manufacturer, or use:

Hours = Annual hours of operation of the air pollution control device, assume customer production schedule or hours of occupancy

LHV = Lower heating value of natural gas

= 983 btu/CF[1885]

HHV = High heating value of natural gas

= 1,031 btu/CF[1886]

0.953 = LHV / HHV conversion factor

To calculate the fossil fuel savings by upgrading from an incinerator to an efficient thermal oxidizer system, the new temperatures must be considered. The addition of heat recovery (either recuperative or regenerative) will increase the inlet temperature, T_I, above that found in the facility.

The calculation should consider changes in the inlet temperature. First, the key temperature required for 99.99% destruction efficiency of various VOC compounds must be determined. The U.S. EPA's Innovative Strategies and Economics Group produced some guidance on the key temperatures[1887] for the following compounds:

VOC Compound	Key Destruction Temperature (°F)
Acrylonitrile	1,344
Allyl chloride	1,276
Benzene	1,350

[1885] Biomass Energy Data Book, 2011, Appendix A: Lower and Higher Heating Values of Gas, Liquid, and Solid Fuels.

[1886] Heat content of natural gas delivered to consumers per the Energy Information Administration, Independent Statistics & Analysis, 2018.

[1887] U.S. Environmental Protection Agency, Incinerators and Oxidizers, Chapter 2, November 2017.

Chlorobenzene	1,407
1,2 – dichloromethane	1,368
Methyl chloride	1,596
Toluene	1,341
Vinyl chloride	1,369

For VOC compounds not listed above, the Key Destruction Temperature should be determined through product literature, equipment vendors, Material Data Safety Sheets (MSDS), or some other source.

When employing heat recovery, either recuperative or regenerative, the increased outlet temperature is limited to the heat exchanger efficiency. This efficiency, or in other words how much heat can be recovered, is limited to the auto-ignition temperatures of the VOCs in the air stream. Regenerative thermal oxidizers offer the advantage of recovering more heat as the combustion can occur within the heat exchanger, whereas with recuperative thermal oxidizers, the heat exchanger efficiency is much lower to prevent premature combustion in the stack of the recuperator.

While the VOCs in the waste air stream have some heating value that contributes to reaching the required chamber temperature, such contributions do not have as high of an impact in the overall energy consumption calculation when compared to the heat exchanger efficiency.

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

Thermal oxidizer operations will have no impact on water or other resources. There may be some safety issues with potential burning hazards from deploying this equipment at high temperatures. There may also be some potential issues with installing outdoor natural gas piping to the location of the thermal oxidizers. In terms of physical sizing, regenerative thermal oxidizers are much larger, thus requiring larger physical space at the site of installation.

DEEMED O&M COST ADJUSTMENT CALCULATION

The ceramic media in the regenerative thermal oxidizer requires regular servicing and may need to be considered as a regular part of facility O&M.

REVIEW DEADLINE: 1/1/2027

4.9.11 Variable Speed Drives for Process Fans

DESCRIPTION

This measure is applied to variable speed drives (VSD) which are installed on non-HVAC fans for process loads. There are separate measures for HVAC pumps and cooling tower fans (4.4.17) and HVAC supply and return fans (4.4.26). VSD process pump applications require custom analysis by the program administrator. The VSD will modulate the speed of the motor when it does not need to run at full load. Since the power of the motor is proportional to the cube of the speed for these types of applications, significant energy savings will result.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The VSD is applied to a motor which does not have a VSD. The application must have a variable load and installation is to include the necessary controls. Savings are based on application of VSDs to a range of baseline load conditions including no control, inlet guide vanes, outlet guide vanes and throttling valves.

DEFINITION OF BASELINE EQUIPMENT

The time of sale baseline is a new motor installed without a VSD or other methods of control. Retrofit baseline is an existing motor operating without a method of variable control. This information shall be collected from the customer.

Installations of new equipment with VSDs which are required by IECC, the energy code as adopted by the State of Illinois are not eligible for incentives.

Note, IECC 2021 became effective statewide as of 1/1/2024. IECC 2018 is the requisite code for any projects with permitting dates spanning July 1, 2019 to 12/31/2023. Prior to July 1, 2019, IECC 2015 is the applicable code. As code requirements and adoption can differ from municipality to municipality, the user should verify which version of code is applicable given these constraints.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 15 years.[1888]

DEEMED MEASURE COST

The costs vary based on the motor horsepower and application. Actual costs should be used. For default cost estimates, please see table below.[1889]

HP	Cost
5 HP	$2,147
10 HP	$2,494
15 HP	$3,940
20 HP	$4,389
25 HP	$4,839
30 HP	$5,289
40 HP	$6,188
50 HP	$7,088
60 HP	$8,463
75 HP	$9,552

[1888] ComEd Effective Useful Life Research Report (2018), Navigant, May 14, 2018

[1889] Default incremental costs are sourced from NEEP Incremental Cost Study (ICS) – Phase II Final Report, Navigant, 2013. The VFD costs from the NEEP ICS was further manipulated in 2017 by iTron to account for inflation, other jurisdictions, and other horsepower and application considerations. The default incremental costs assume an average between VFDs with and without bypasses and adjusted to 2023 values to account for inflation.

HP	Cost
100 HP	$11,365

LOADSHAPE

Time-based schedule considerations are required to perform energy savings calculations and should be concurrently used to establish the savings loadshape that is in alignment with relevant loadshape components and definitions.

COINCIDENCE FACTOR

The demand savings factor (DSF) is already based upon coincident savings, and thus there is no additional coincidence factor for this characterization.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$\text{kWh}_{\text{Base}} = \left(0.746 \times HP \times \frac{LF}{\eta_{motor}}\right) \times RHRS \times \sum_{0\%}^{100\%} (\%FF \times PLR_{Base})$

$\text{kWh}_{\text{Retrofit}} = \left(0.746 \times HP \times \frac{LF}{\eta_{motor}}\right) \times RHRS \times \sum_{0\%}^{100\%} (\%FF \times PLR_{Retrofit})$

$ESF = (\text{kWh}_{\text{Base}} - \text{kWh}_{\text{Retrofit}})/\text{kWh}_{\text{Base}}$

$\Delta\text{kWh}_{\text{total}} = \text{kWh}_{\text{Base}} \times ESF$

Where:

kWh_{Base} = Baseline annual energy consumption (kWh/yr)

$kWh_{Retrofit}$ = Retrofit annual energy consumption (kWh/yr)

ESF = Energy savings factor; If ESF is greater than 67%, cap the ESF at 67% for process fan VSD improvements.[1890]

ΔkWh_{total} = Total project annual energy savings

0.746 = Conversion factor for HP to kWh

HP = Nominal horsepower of controlled motor

LF = Load Factor; Motor Load at Fan Design CFM (Default = 65%)[1891]

η_{motor} = Installed nominal/nameplate motor efficiency

= Default motor is a NEMA Premium Efficiency, ODP, 4-pole/1800 RPM fan motor

NEMA Premium Efficiency Motors Default Efficiencies[1892]

[1890] *Recommendations for Verifying Savings for non-HVAC VFDs* memorandum calculated an energy savings limit of 67% for process fans using the Toshiba Energy Savings Software for Motors and Drives (2009 version).

$\sum_{0\%}^{100\%}(\%FF \times PLR)$ = The sum of the product of the percentage of run-time spent within a given flow fraction range (%FF) and the part load ratio for a given flow fraction range based on the retrofit flow control type.

Example: A process fan with discharge damper controls operates 85% of the time at 75% flow fraction, 5% of the time at 80% flow fraction, and 10% of the time at 95% flow fraction:

$\sum_{0\%}^{100\%}(\%FF \times PLR)$ = (0.85 x 0.93) + (0.05 x 0.97) + (0.10 x 1.00)

= 0.939%

SUMMER COINCIDENT PEAK DEMAND SAVINGS

kW_{Base} = $\left(0.746 \times HP \times \frac{LF}{\eta_{motor}}\right) \times PLR_{Base,FFpeak}$

$kW_{Retrofit}$ = $\left(0.746 \times HP \times \frac{LF}{\eta_{motor}}\right) \times PLR_{Retrofit,FFpeak}$

ΔkW_{fan} = $kW_{Base} - kW_{Retrofit}$

Where:

kW_{Base} = Baseline summer coincident peak demand (kW)

$kW_{Retrofit}$	= Retrofit summer coincident peak demand (kW)
ΔkW_{fan}	= Fan-only summer coincident peak demand impact
ΔkW_{total}	= Total project summer coincident peak demand impact
$PLR_{Base,FFpeak}$	= The part load ratio for the average flow fraction between the peak daytime hours during the weekday peak time period based on the baseline flow control type (default average flow fraction during peak period = 90%)
$PLR_{Retrofit,FFpeak}$	= The part load ratio for the average flow fraction between the peak daytime hours during the weekday peak time period based on the retrofit flow control type (default average flow fraction during peak period = 90%)

4.9.12 Low Flow Toilets and Urinals

DESCRIPTION

Toilets and urinals are found in bathrooms located in commercial, and industrial facilities. The first federal standards dealing with water consumption for toilets and urinals was the Energy Policy Act of 1992. It specified a gallon per flush (gpf) standard for both fixtures. These standards are used to define the baseline equipment for this measure. The Subsequent U.S. EPA WaterSense program in 2009 set even tighter standards for plumbing fixtures, including toilets and urinals. These standards are used to define the efficient equipment for this measure.

DEFINITION OF EFFICIENT EQUIPMENT

The high efficiency equipment is either a U.S. EPA WaterSense certified commercial toilet fixture or commercial urinal.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a toilet or urinal that has a maximum gallons per flush outlined by the Energy Policy Act of 1992.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated useful life for this measure is assumed to be 25 years for both toilets and urinals.[1893]

DEEMED MEASURE COST

The incremental costs for both toilets and urinals are $0.[1894]

LOADSHAPE

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

The following savings should be included in the total savings for this measure but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$\Delta kWh = \Delta Water / 1{,}000{,}000 * E_{water}$ total

E_{water} = IL Total Water Energy Factor (kWh/Million Gallons)

= 5,010[1895]

[1893] ATD Home Inspection: http://www.atdhomeinspection.com/advice/average-product-life/ is 50 years. 25 years is used to be conservative.

[1894] Measure cost assumption from City of Fort Collins, "Green Building Practice Summary," March 21, 2011, page 2. The document states "Information from the EPA WaterSense web site: WaterSense® labeled toilets are not more expensive than regular toilets. MaP testing results have shown no correlation between price and performance. Prices for toilets can range from less than $100 to more than $1,000. Much of the variability in price is due to style, not functional design."

[1895] This factor includes 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information, please review Elevate Energy's Review 'IL TRM: Energy per Gallon Factor, May 2018'.

Toilet Calculation:

For example, a low flow toilet is installed in a commercial location.

ΔkWh = 491 gal/year / 1,000,000 * 5,010 kWh/million gallons

= 2.5 kWh/year

Urinal Calculation:

For example, a low flow urinal is installed in a commercial location.

ΔkWh = 2,340 gal/year / 1,000,000 * 5,010 kWh/million gallons

= 11.7 kWh/year

4.9.13 Smart Irrigation Controls

DESCRIPTION

Irrigation systems are commonly found on commercial properties, educational institutions, public parks, golf courses, and other facilities with landscaped grounds. They are typically operated on timers, applying the irrigation water in the early morning or after dusk. The timing and duration of irrigation application are determined by the user, along with the location and density of sprinklers. The irrigation water gets applied according to the control schedule, regardless of whether the landscape actually needs the irrigation water at that time.

The new measure involves the installation of a control system technology that reduces or eliminates irrigation during times of precipitation or when there is already sufficient soil moisture. This measure applies to landscape irrigation systems for commercial, institutional, and public properties only. It does not apply to agricultural irrigation systems for crops or residential landscape irrigation systems.

This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Smart Irrigation Controls utilize sensors, gauges, or local weather forecasts to regulate the application of irrigation water to lawn or landscape vegetation. There are two main technologies used for this purpose: 1) Precipitation based smart irrigation controllers, and 2) Soil-moisture based smart irrigation controllers.

Precipitation Based Smart Irrigation Controllers

This type of system utilizes either an on-site rain gauge or a local weather service to determine if there is sufficient precipitation to allow shut-off of the irrigation water.

Soil Moisture Based Smart Irrigation Controllers

This type of system utilizes soil moisture sensors, buried in the root zone, to determine if irrigation water is needed. A "suspended cycle irrigation system" uses the soil moisture sensors to determine whether a regularly scheduled irrigation application is necessary. If there is sufficient soil moisture, then the next scheduled irrigation cycle gets interrupted. A "water-on-demand irrigation system" applies irrigation water when the moisture sensor reaches its lower limit and shuts off when the moisture sensor reaches its upper limit. There is no regularly scheduled irrigation with the water on demand system.

For the purposes of this measure characterization, the assumed rolling 24-hour threshold for shutting off the irrigation is 6 mm (0.24"). The Savings Factor is based on the percentage of time that the rolling 24-hour average of precipitation meets or exceed the 6 mm threshold.

DEFINITION OF BASELINE EQUIPMENT

The baseline irrigation system applies irrigation water to the lawn or landscape on a regularly scheduled timer. The timing and duration of irrigation application are determined by the user, along with the location and density of sprinklers. The irrigation water gets applied according to the control schedule, regardless of whether the landscape actually needs the irrigation water at that time.

Sprinkler head nozzles have a variety of configurations that affect the distribution of the irrigation water. The water can come in the form of a spray, a rotating plume, a bubbler, or a drip.

Typical baseline irrigation systems provide 1 inch of irrigation to the entire lawn. This is equivalent to 0.623 gallons per square foot of lawn per week.[1904]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected useful life for Irrigation Control Measures is assumed to be 15 years.

[1904] Today's Homeowner with Danny Lipford. "How to Calculate Lawn Irrigation Water Usage and Costs."

DEEMED MEASURE COST

The measure cost for a multi-zone smart irrigation control system is $500.[1905]

Algorithm

CALCULATION OF ENERGY SAVINGS

Energy savings from Irrigation Control Measures are the result of reduced water consumption. There are indirect electric energy savings from reduced potable water treatment.

ELECTRIC ENERGY SAVINGS

The electric energy savings are based indirectly on the reduced electricity usage used to provide the potable water and treat the wastewater. By applying an "Energy Factor", the water savings (in gallons/year) can be converted to electricity savings (in kWh/year). This "Energy Factor" considers the electric energy requirements of potable water treatment plants and potable water distribution. Since the "wasted" irrigation water in the baseline case will likely be absorbed into the soil or will runoff into surface water bodies, electricity savings from a reduction in wastewater treatment load would not apply.

The methodology for quantifying the water savings involves a direct comparison of the baseline equipment to the efficient equipment. In order to calculate the baseline water usage of an irrigation system, the number of sprinklers and their sizing need to be determined. The static pressure and sizing of the water service, along with the sprinkler head orifice sizing will ultimately determine the flow rate of water.

The electricity savings for this measure can be calculated by applying an energy factor to the calculated water savings.

$$\Delta kWh_{water} = \Delta Water / 1{,}000{,}000 * E_{water}$$

Where:

E_{water} = Illinois Total Water Energy Factor (kWh/Million Gallons)
=2,571[1906]

The total water savings for this measure can be calculated as follows:

$$\Delta Water = BSFL – ESFL$$

Where:

$\Delta Water$ = Total Water Savings (gallon/season)

The baseline volumetric flow rate for the entire system can be calculated as follows:

$$BSFL = NOS \times SFL \times DOI \times NAY$$

[1905] Material pricing taken from Google shopping search on "smart irrigation control system". The Rain Bird Smart LNK WiFi Irrigation System Indoor Controller (4 Pack) sells for $316 from online retailer Wish.com. Installation labor pricing taken from online retailer Home Advisor – Lawn and Garden, Repair a Sprinkler System**Error! Hyperlink reference not valid.** which stated $45 to $200 per hour for a plumber.

[1906] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

Where:

BSFL	= Baseline System Flow Rate (gallon/year)
NOS	= Number of Sprinklers, the total number of sprinklers at the property = Actual
SFL	= Sprinkler Flow Rate (gallon/minute) = Actual, site-specific irrigation system specifications should be consulted to determine the property's sprinkler flow rate
DOI	= Duration of Irrigation (minutes/application) = Actual, the baseline scheduling controls should be used to determine the irrigation season
NAY	= Number of Applications per Year (application/year) = Actual

The efficient volumetric flow rate can be calculated as follows:

$$ESFL = BSFL \times (1 - SF)$$

Where:

ESFL	= Efficient System Flow Rate (gallon/season)
BSFL	= Baseline System Flow Rate (gallon/season)
SF	= Savings Factor

The volumetric flow rate for the entire efficient system is based on applying a Savings Factor (SF) to the BSFL. The SF is determined by calculating the number of weeks in the irrigation season (April 25 through October 13) when there is sufficient precipitation to allow the shutoff of the irrigation system. Typical Meteorological Year (TMY-3) data gives precipitation depth in millimeters for each hour of the typical year. By consulting the TMY-3 data for the closest applicable weather station, the SF can be determined.

One source recommends a rain sensor shut-off threshold of 6 mm of precipitation for twice or thrice weekly irrigation schedule or 13 mm of precipitation for once weekly irrigation schedule.[1907] For the purposes of this workpaper, we will use a rolling 24-hour threshold of 6 mm.

The State Climatologist Office for Illinois produced a map of the Illinois Growing Season days per year for different parts of the state.[1908] Using a growing season average of 170 days, the "irrigation season" begins on April 25 and end on October 13.

By analyzing the TMY-3 precipitation data, the number of weeks during the "irrigation season" that the rolling 24-hour precipitation levels greater than 6 mm can be determined, along with the Savings Factors:

Chicago:	SF = 0.265
Midway:	SF = 0.241
Rockford:	SF = 0.268
Peoria:	SF = 0.227
Springfield:	SF = 0.186

[1907] Michael D. Dukes. "Smart Irrigation Controllers: What Makes an Irrigation Controller Smart". University of Florida, Institute for Food & Agricultural Sciences.

[1908] State Climatologist Office for Illinois, Illinois State Water Survey, 2003. Based on 1971 – 2000 data, assessing the number of days between the last spring drop below 32 degrees and the firest fall drop below 32 degrees.

For example, an irrigation system in Rockford with 50 sprinklers running at 5 gallons per minute, 20 minutes per sprinkle with 100 sprinkles per year would save:

$\Delta kWh = \Delta Water / 1{,}000{,}000 * E_{water}$

$\Delta Water = BSFL - ESFL$

$BSFL = NOS * SFL * DOI * NAY$

$= 50 * 5 * 20 * 100$

$= 500{,}000$

$ESFL = BSFL * (1 - SF)$

$= 500{,}000 * (1 - 0.268)$

$= 366{,}000$

$\Delta Water = 500{,}000 - 366{,}000$

$= 134{,}000$

$\Delta kWh = 134{,}000 / 1{,}000{,}000 * 2571$

$= 344.5$ kWh

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

The water savings inherent in the efficient irrigation control technology will help preserve water supplies and extend the life of water treatment and wastewater treatment equipment. By reducing irrigation during periods of precipitation, unnecessary storm runoff and puddling can be avoided. For more details on calculating water savings, please see the 'Algorithm' section of this characterization.

DEEMED O&M COST ADJUSTMENT CALCULATION

Maintaining an Efficient Irrigation Control system will require periodic cleaning and calibration of the sensors. Any wiring or wireless communication devices will also need to be maintained. Costs for these activities is $196.[1909]

MEASURE CODE: CI-MSC-SIRC-V03-250101

4.9.14 Switch Peripheral Equipment Consolidation

DESCRIPTION

This measure will allow for projects with small scopes of equipment replacement to be cost effectively brought into the telecommunication optimization incentive program. Consolidating telecommunication line and trunk equipment eliminate underutilized equipment which reduces power draw from the rectifier. This avoided heat load also results in cooling savings.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The measure requires no new equipment and only consolidates partially loaded equipment. There are a myriad of different types of line and trunk equipment, but consolidation eliminates underutilized equipment which will result in energy savings.

DEFINITION OF BASELINE EQUIPMENT

Baseline telecommunications equipment is partially loaded line and trunk equipment that is no longer needed due to line loss on the telecommunications network. Lines are consolidated to like equipment and the underutilized equipment is removed. This applies to all line and trunk equipment and does not exclude participation from any particular type of line and trunk equipment. All line and trunk equipment are considered eligible but only up to and including 40 pieces of equipment. Above that amount, projects will require on-site amp reduction verification.

Baseline cooling equipment is assumed to be an Air-Cooled Chiller without an economizer with a capacity >240 MBtu. If cooling equipment can be verified, the chiller efficiency can be replaced with the appropriate value using Table below.

ASHRAE 90.1 2016: Table 6.8.1-11

**Default value based on previous program data; in all but one project, this was the cooling efficiency value used*

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

10 years.[1910]

DEEMED MEASURE COST

There is no equipment cost to implement this measure. The only associated cost is the required internal labor to move lines from the to-be-removed piece of equipment to the chosen like piece of equipment. The default labor cost is $742/piece of equipment removed.[1911]

LOADSHAPE

Loadshape is determined by the constant power draw by the line and trunk equipment; default loadshape is: Loadshape C53 – Flat.

COINCIDENCE FACTOR

Coincidence Factor is determined by the constant power draw by the line and trunk equipment; the summer peak coincidence factor for the line and trunk equipment is assumed to be 100%. The cooling coincident factor is assumed to be consistent with the summer system peak coincidence factor as provided below:

CF_{SSP} = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1912]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\text{kWh Savings} = \text{p} * \text{kW}_{\text{Trunk}} * (1 + \text{LCF} * \text{CE}) * \text{t}$$

Where:

p = Number of pieces of redundant equipment removed

= Actual

kW_{Trunk} = Average line and trunk equipment power draw

= 0.233 kW[1913]

LCF = Load Conversion Factor kW to Ton of cooling (tons/kW)

= 0.284 [1914]

CE = Cooling Efficiency

[1910] Assumption is based on communication from AT&T program manager indicating an expectation that consolidated equipment should be expected to remain for a minimum of 10 years.

[1911] Value based on the average of program data provided by Franklin Energy. See "Network Combing Workpaper Research_v2.xls" for details. Note projects were capped at 40 pieces of equipment in the development of this average.

[1912] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

[1913] Value based on the average of program data provided by Franklin Energy. See "Network Combing Workpaper Research_v2.xls" for details. Note projects were capped at 40 pieces of equipment in the development of this average.

[1914] 1 ton of cooling = 12,000 BTU/h. 1kWh = 3412 BTU. Therefore 1 ton of cooling = 12000BTU/h * 1 kWh/3412 BTU = 3.51 kW per ton, = 0.284 tons/kW.

= Actual, if unknown assume 1.90 kW/ton[1915]

t = time (hours)

= 8,760 hours

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\text{kW Savings} = \text{p} * \text{kW}_{\text{Trunk}} * (\text{CF}_{\text{Trunk}} + \text{LCF} * \text{CE} * \text{CF}_{\text{SSPCool}})$$

Where:

p = Number of pieces of redundant equipment removed

kW_{Trunk} = Average line and trunk equipment power draw, 0.233 kW

LCF = Load Conversion Factor kW to Ton, 0.284

CE = Cooling Efficiency, default value = 1.90 kW/ton based on previous program data

CF_{Trunk} = Line and Trunk Equipment Coincidence Factor, 1.0

$CF_{SSPCool}$ = Summer System Peak Coincidence Factor for Commercial cooling (during system peak hour)

= 91.3% [1916]

MEASURE CODE: CI-MSC-SPEC-V02-230101

REVIEW DEADLINE: 1/1/2027

[1915] Cooling efficiency kW/ton default is based on air cooled units >240 Mbtuh, upflow ducted value as per the ASHRAE 90.1 2016 tables provided in the baseline section. This was the appropriate cooling efficiency value for all but one of Franklin Energy's projects.

[1916] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The AC load during the utility's peak hour is divided by the maximum AC load during the year.

4.9.15 ENERGY STAR Low Wattage Uninterruptible Power Supply

DESCRIPTION

This measure is for replacing an inefficient uninterruptable power supply (UPS) with an efficient ENERGY STAR[1917] rated UPS in telecommunications, or similar facility that operates continuously. Note for data centers and other facilities that are not operated similarly to telecommunication applications, a custom calculation based on M&V analysis and that accounts for ramp-up of loads on the UPS should be performed. UPS units provide backup power in data centers and draw power constantly to keep their batteries charged. Uninterruptible power supplies (UPS) are utilized in many organizations to protect themselves from downtime with power distribution and avoid data processing errors due to downtimes. UPS systems are connected between the public power distribution system and mission critical loads.

This measure applies to UPS's with a rated output power less than or equal to 1,875 watts.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is a new ENERGY STAR UPS in a telecommunication or similar application. For single-normal mode UPSs, the installed system must meet or exceed the average loading-adjusted efficiency values required by the ENERGY STAR program. The new UPS must have a rated output power less than or equal to 1,875 watts, the limit of the scope of the federal UPS standard.[1918]

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is an existing non-ENERGY STAR UPS in a telecommunication or similar application.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 15 years.[1919]

DEEMED MEASURE COST

The incremental cost is estimated at $59 per UPS unit.[1920]

LOADSHAPE

Loadshape is determined by the constant power draw by the UPS; default loadshape is Loadshape C53 – Flat.

COINCIDENCE FACTOR

The coincidence factor for the UPS or rectifier is assumed to be 1.0 due to equipment operating during peak period.

[1917] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[1918] Code of Federal Regulations, Energy Conservation Standards for Uninterruptible Power Supplies, effective January 10, 2022 (10 CFR 430.32(z)(3).

[1919] California Municipal Utilities Association. Savings Estimation Technical Reference Manual 2017, Third Edition. Section 8.12, p. 8–15.

[1920] As estimated in the California Municipal Utilities Association. Savings Estimation Technical Reference Manual 2017, incremental measure cost based on average UPS costs for a range of sizes, assuming a 30% premium for an ENERGY STAR UPS.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = Size * (1/Eff_{AVGbase} - 1/Eff_{AVGee}) * EFLH$$

Where:

Size = Size of UPS in rated output power, kW

$Eff_{AVGbase}$ = Efficiency of existing UPS

= Actual or use table below[1921]

UPS Product Class	Rated Output Power	Minimum Efficiency
Voltage and Frequency Dependent (VFD)	P ≤ 300 W	$-1.20\times10^{-6} \times P^2 + 7.17\times10^{-4} \times P + 0.862$
	300 W < P ≤ 700 W	$-7.85\times10^{-8} \times P^2 + 1.01\times10^{-4} \times P + 0.946$
	P > 700 W	$-7.23\times10^{-9} \times P^2 + 7.52\times10^{-6} \times P + 0.977$
Voltage Independent (VI)	P ≤ 300 W	$-1.20\times10^{-8} \times P^2 + 7.19\times10^{-4} \times P + 0.863$
	300 W < P ≤ 700 W	$-7.67\times10^{-8} \times P^2 + 1.05\times10^{-4} \times P + 0.946$
	P > 700 W	$-4.62\times10^{-9} \times P^2 + 8.54\times10^{-6} \times P + 0.979$
Voltage and Frequency Independent (VFI)	P ≤ 300 W	$-3.13\times10^{-8} \times P^2 + 1.960\times10^{-4} \times P + 0.543$
	300 W < P ≤ 700 W	$-2.60\times10^{-8} \times P^2 + 3.65\times10^{-4} \times P + 0.764$
	P > 700 W	$-1.70\times10^{-8} \times P^2 + 3.85\times10^{-6} \times P + 0.876$

Eff_{AVGee} = Efficiency of new ENERGY STAR UPS

= Actual or ENERGY STAR minimum value from table below[1922]

Rated Output Power	UPS Product Class		
	VFD	VI	VFI
P ≤ 350 W	$5.71 \times 10^{-5} \times P + 0.962$	$5.71 \times 10^{-5} \times P + 0.964$	$0.011 \times \ln(P) + 0.824$
350 W < P ≤ 1.5 kW	0.982	0.984	$0.011 \times \ln(P) + 0.824$
1.5 kW < P ≤ 1.875 kW	$0.981 - E_{MOD}$	$0.981 - E_{MOD}$	$0.0145 \times \ln(P) + 0.8 - E_{MOD}$

E_{MOD} = an allowance of 0.004 for Modular UPSs applicable in the commercial 1500 – 10,000 W range

EFLH = Equivalent Full Load Hours, per equation below and values provided in table[1923]

$= (t_{0.25} \times 0.25 + t_{0.5} \times 0.5 + t_{0.75} \times 0.75 + t_{1.0} \times 1.0) \times 8760$ hours

Rated Output Power (P) in watts	UPS Product Class	Time spent at specified proportion of reference test load (t)				EFLH
		25%	50%	75%	100%	
P ≤ 1.5 kW	VFD	0.2	0.2	0.3	0.3	5913
	VI or VFI	0	0.3	0.4	0.3	6570
1.5 kW < P ≤ 1.875 kW	VFD, VI, or VFI	0	0.3	0.4	0.3	6570

[1921] Code of Federal Regulations, Energy Conservation Standards for Uninterruptible Power Supplies, effective January 10, 2022 (10 CFR 430.32(z)(3).

[1922] ENERGY STAR Uninterruptible Power Supplies Final Version 2.0 Specification, effective January 1, 2019.

[1923] Calculation and inputs provided in ENERGY STAR Uninterruptible Power Supplies Final Version 2.0 Specification.

Default Energy Savings are provided below:[1924]

Output Power Range	Output Power (kW)[1925]	Single-Normal Mode UPS Systems			Multiple-Normal Mode UPS Systems	
		VFD	VI	VFI	$VFD_{25\%}/VI_{75\%}$	$VFD_{25\%}/VFI_{75\%}$
P ≤ 0.300 kW	0.261	185.6	207.7	1,035.4	186.0	727.7
0.300 kW < P ≤ 0.350 kW	0.335	34.7	40.9	169.5	35.3	127.4
0.350 kW < P ≤ 0.700 kW	0.513	117.3	133.5	283.2	118.0	234.4
0.700 kW < P ≤ 1.500 kW	1.041	32.0	35.5	354.6	32.0	264.2
1.500 kW < P ≤ 1.875 kW	1.766	0.0	55.3	605.0	13.9	434.1

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = Size * (1/Eff_{AVGbase} - 1/Eff_{AVGee}) * CF$$

Where:

CF_{IT} = Coincidence factor of UPS

= 1.0

Default Summer Peak Demand Savings are provided below based on defaults above:

Output Power Range	Single-Normal Mode UPS Systems			Multiple-Normal Mode UPS Systems	
	VFD	VI	VFI	$VFD_{25\%}/VI_{75\%}$	$VFD_{25\%}/VFI_{75\%}$
P ≤ 0.300 kW	0.0314	0.0316	0.1576	0.0314	0.1108
0.300 kW < P ≤ 0.350 kW	0.0059	0.0062	0.0258	0.0060	0.0194
0.350 kW < P ≤ 0.700 kW	0.0198	0.0203	0.0431	0.0200	0.0357
0.700 kW < P ≤ 1.500 kW	0.0054	0.0054	0.0540	0.0054	0.0402
1.500 kW < P ≤ 1.875 kW	0.0000	0.0084	0.0921	0.0021	0.0661

REVIEW DEADLINE: 1/1/2028

[1924] Default savings are provided in a calculation file provided by VEIC that utilizes the ENERGY STAR qualified products list (as accessed on June 11, 2024) for the average power rating within each range. In circumstances where the use of the efficient and baseline efficiency formulas resulted in negative default savings, the average unit efficiency from qualified products within that power range was used instead of the ENERGY STAR product class formula. See "ENERGY STAR UPS Calculations_2024.xls" for more information.

[1925] Default output power is based on the average active output power rating of ENERGY STAR rated models falling into that specified range, as sourced from the ENERGY STAR Qualified Products List for Uninterruptible Power Supplies, as accessed on June 11, 2024.

4.9.16 Energy Efficient Rectifier and High Wattage UPS

DESCRIPTION

This measure is for replacing an inefficient rectifier or high wattage uninterruptable (UPS) with an efficient unit in a data center, telecommunications, or similar facility that operates continuously. A rectifier converts alternating current (AC) to direct current (DC). UPS units provide backup power and draw constantly to keep batteries charged.

This measure applies to UPS's with a rated output power greater than 1,875 watts.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is a new rectifier or UPS whose efficiency in normal mode (not in energy saver mode) is at least 94%.[1926]

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is an existing rectifier or UPS whose efficiency in normal mode (not in energy saver mode) is less than 90%.[1927]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 15 years.[1928]

DEEMED MEASURE COST

The incremental cost is estimated at $59 per kW of IT Load.[1929]

LOADSHAPE

Loadshape is determined by the constant power draw by the Rectifier; default loadshape is Loadshape C53 – Flat.

COINCIDENCE FACTOR

The coincidence factor for the rectifier is assumed to be 1.0 due to equipment operating during peak period.

Algorithm

[1926] Switching mode rectifier (SMR) technologies allows for efficiencies as high as 96% according to the DOE, Office of Energy Efficiency & Renewable Energy, High-Efficiency, Wide-Band Three-Phase Rectifiers and Adaptive Rectifier Management. Accessed: 12/05/19 https://www.energy.gov/eere/amo/high-efficiency-wide-band-three-phase-rectifiers-and-adaptive-rectifier-management

[1927] Mid-range efficiency for most low peak rectifiers (88%-92%) based on information from the DOE, Office of Energy Efficiency & Renewable Energy, High-Efficiency, Wide-Band Three-Phase Rectifiers and Adaptive Rectifier Management. Accessed: 12/05/19 https://www.energy.gov/eere/amo/high-efficiency-wide-band-three-phase-rectifiers-and-adaptive-rectifier-management

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = kWh_{base} - kWh_{EE}$$

$$kWh_{base} = ((Load * H_{IT})/Eff_{base}) + ((Load * (1/ Eff_{base} – 1) * H_{Cool} * kW/Ton_{Cool} * 3412/12000)$$

$$kWh_{EE} = ((Load * H_{IT})/Eff_{EE}) + ((Load * (1/ Eff_{EE} – 1) * H_{Cool} * kW/Ton_{Cool} * 3412/12000)$$

Where:

Load = Average IT load (output kW)

= Actual, typically at 20% of equipment rated load[1930]

H_{IT} = Annual hours of operation of rectifier or UPS

= 8760

H_{cool} = Annual cooling system hours of operation

= Actual or defaults below:

System Size	Cooling Hours (H_{cool})
Small IT (≤ 50 kW) without air-side economizer	8760 hours[1931]
Small IT (> 50 kW) with air-side economizer	4380 hours[1932]

Eff_{base} = Efficiency of existing rectifier or UPS

= Actual. If unknown assume 90%[1933]

Eff_{EE} = Efficiency of new rectifier or UPS

= Actual. If unknown assume 94%

kW/Ton_{cool} = Cooling system efficiency (kW/Ton)

Cooling Equipment Type	Efficiency Calculation (kW/Ton_{cool})
Air-Cooled Chiller	$kW/Ton_{Chiller} + kW_{chilled\ water\ pump}$ /Tons
Water-Cooled Chiller	$kW/Ton_{Compressor} + (kW_{chilled\ water\ pump} + kW_{condensor\ water\ pump} + kW_{cooling\ tower\ fans})$/Tons
Direct Expansion System	12/EER

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = kW_{base} - kW_{EE}$$

$$kW_{base} = ((Load * CF_{IT})/Eff_{base}) + ((Load * CF_{cool} * (1/ Eff_{base} – 1) * kW/Ton_{Cool} * 3412/12000)$$

$$kWh_{EE} = ((Load * CF_{IT})/Eff_{EE}) + ((Load * CF_{cool} * (1/ Eff_{EE} – 1) * kW/Ton_{Cool} * 3412/12000)$$

Where:

[1930] Based on industry knowledge of large telecom company set up.

[1931] Small IT systems are assumed to have no air-side economizer and to operate continuously throughout the year.

[1932] Larger IT systems are assumed to have an air-side economizer that allows the cooling system to be turned off for half the year. This corresponds to approximately a 45°F changeover temperature, which is a conservative assumption.

[1933] Mid-range efficiency for most low peak rectifiers (88%-92%) based on information from the DOE, Office of Energy Efficiency & Renewable Energy, High-Efficiency, Wide-Band Three-Phase Rectifiers and Adaptive Rectifier Management.

CF_{IT} = Coincidence factor of rectifier

= 1.0

CF_{cool} = Coincidence factor of cooling system

= 0.82

4.9.17 Energy Efficient Hydraulic Oils - Provisional Measure

DESCRIPTION

Industrial hydraulic systems use hydraulic oil to transfer input energy to output power. Hydraulic oils also protect critical components from premature wear. Energy efficient hydraulic oil lubricants meet these requirements and provide reduced energy consumption. Energy efficient hydraulic oils have a lower coefficient of friction which reduces the friction between two moving parts (rotating pump equipment and hydraulic oil). This lower coefficient of friction reduces the energy required to yield output power. Second, these oils have a high viscosity index which reduces the effect temperature has on the viscosity of the hydraulic oil. The high viscosity index allows constant viscosity over a range of operating temperatures which optimizes volumetric and mechanical efficiency at the pumps rated output. Additionally, energy efficient hydraulic oils reduce the operating temperature of the hydraulic system.

Manufacturers who use electric-motor-driven hydraulic systems have been found to reduce energy consumption by between 3 and 7%.

This measure was developed to be applicable to the following program types: NC, TOS and RF. If applied to other program types, the measure should be verified as a custom measure.

DEFINITION OF EFFICIENT EQUIPMENT

This is applicable for small, medium, and large manufacturers in all climate zones using electric motors to power their hydraulic system both inside and/or outside conditioned areas; or for all hydraulic systems on mobile equipment in all climate zones on Illinois.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is defined as hydraulic systems using non-energy efficient industrial hydraulic oils which provides no energy efficiency benefits. In the formula below, the baseline equipment is where, Ei = zero.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.

The ability to reduce energy consumption (energy efficiency) is an inherent characteristic in the oil which does not deplete over time. As long as the energy efficient oil is in use, it will provide energy efficiency.

DEEMED MEASURE COST

The actual incremental costs between an energy-efficient hydraulic oil and a standard hydraulic oil should be used.

LOADSHAPE

Loadshape C14: Indust. 1-shift (8/5) (e.g., comp. air, lights)
Loadshape C15: Indust. 2-shift (16/5) (e.g., comp. air, lights)
Loadshape C16: Indust. 3-shift (24/5) (e.g., comp. air, lights)
Loadshape C17: Indust. 4-shift (24/7) (e.g., comp. air, lights)

COINCIDENCE FACTOR

No coincidence factor though it is noted that reduced consumption for equipment will reduce the overall baseload power demand, especially if a construction operation or manufacturing operation demand more utility power in summer weather (e.g., construction ground work, rubber manufacturing, etc).

Algorithm

CALCULATION OF ENERGY SAVINGS

Savings are calculated based on a reduced coefficient of friction and the shear-stable high viscosity index value associated with energy-efficient hydraulic oils in hydraulic systems. The algorithm below for Energy Savings, is modeled after the Focus on Energy Emerging Technology Program M&V study.

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = MotorHP * (0.746\ kW/HP) * (\%MotorLoading / \mu Motor) * HOURS * Ei$$

Where:

MotorHP = Rated horsepower of electric motor, summed when pumps are in series.

= Actual

%MotorLoading = Is dependent upon many factors including the part being manufactured, the polymer, the machine's specifications, and cycle time.

= Actual, calculated as (Average load / Full rated load)

= Estimated as 75%.[1934]

µMotor = Motor efficiency

= Actual. If unknown, estimated as 92% for motors in size range typically used.[1935]

HOURS = Hours of operation per year

= Actual

Ei = Efficiency improvement due to use of energy efficient hydraulic oils

= Actual. If not measured, assume 3.3%.[1936]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

O&M savings from the necessary standard oil replacement over the lifetime of the energy efficient hydraulic oil (including oil cost, disposal costs, labor and avoided downtime) should be calculated. If additional savings for improved pump and valve lifetime can be demonstrated, these can also be included.

An example O&M cost calculation is provided below, relating to the standard hydraulic oil requiring 1 change out per year:

[1934] Most electric motors are designed to run at 50% to 100% of rated load, from Department of Energy "Determining Electric Motor Load & Efficiency", June 23, 2020.

[1935] Based on common size and type of motor - chart on pages 13-14, "Attachment C" of reference 9, the efficiency of a 50HP motor (TEFC type) at 1200 RPM is 92%. Or 75HP at 900 RPM at 75% TEFC type is 91.8%. These are common sizes and type for manufacturers.

[1936] Estimate based on review of a number of studies provided by ExxonMobil and saved in reference folders.

O&M Component	Cost
Oil cost	$800
Oil disposal cost	$80
Labor (4 hours per change at $40/hr)	$160
Downtime Production cost (2 hours at $500 lost production cost per year)	$1000
Total annual O&M benefit (1 change per year)	$2040

4.9.18 Energy Efficient Gear Lubricants - Provisional Measure

DESCRIPTION

Industrial gear reduction systems use gear oil to transfer input energy to output power. Gear oils also protect critical components from premature wear. Energy efficient gear oil lubricants meet these requirements and provide reduced energy consumption. Energy efficient gear oils have a lower coefficient of friction which reduces the friction between two moving parts (rotating pump equipment and hydraulic oil). This lower coefficient of friction reduces the energy required to yield output power. Second, these oils have a high viscosity index which reduces the effect temperature has on the viscosity of the hydraulic oil. The high viscosity index allows constant viscosity over a range of operating temperatures which optimizes volumetric and mechanical efficiency at the pumps rated output. Additionally, energy efficient gear oils reduce the operating temperature of the gear-reduction gearbox.

Manufacturers who use electric-motor-driven gear-reduction gearboxes can reduce energy consumption by up to 1% per gear-mesh (e.g., 3% efficiency for a 3-reduction gearbox).

This measure was developed to be applicable to the following program types: NC, TOS and RF. If applied to other program types, the measure should be verified as a custom measure.

DEFINITION OF EFFICIENT EQUIPMENT

This is applicable for small, medium, and large manufacturers in all climate zones using electric motors to power their gear reduction system both inside and/or outside conditioned areas; or for all gear reduction systems on mobile equipment in all climate zones on Illinois.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is defined as a gearbox using non-energy efficient industrial gear lubricants which provides no energy efficiency benefits. In the formula below, the baseline equipment is where, Ei = zero.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.

The ability to reduce energy consumption (energy efficiency) is an inherent characteristic in the oil which does not deplete over time. As long as the energy efficient oil is in use, it will provide energy efficiency.

DEEMED MEASURE COST

The actual incremental costs between an energy-efficient and a standard gear lubricant should be used.

LOADSHAPE

Loadshape C14: Indust. 1-shift (8/5) (e.g., comp. air, lights)
Loadshape C15: Indust. 2-shift (16/5) (e.g., comp. air, lights)
Loadshape C16: Indust. 3-shift (24/5) (e.g., comp. air, lights)
Loadshape C17: Indust. 4-shift (24/7) (e.g., comp. air, lights)

COINCIDENCE FACTOR

No coincidence factor though it is noted that reduced consumption for equipment will reduce the overall baseload power demand, especially if a construction operation or manufacturing operation demand more utility power in summer weather (e.g., construction ground work, rubber manufacturing, etc).

Algorithm

CALCULATION OF ENERGY SAVINGS

Savings are calculated based on a reduced coefficient of friction and the shear-stable high viscosity index value associated with energy-efficient gear oils in gear-reduction systems. The algorithm below for Energy Savings is modeled after the Focus on Energy Emerging Technology Program M&V study.

ELECTRIC ENERGY SAVINGS

ΔkWh = MotorHP * (0.746 kW/HP) * (%MotorLoading / µMotor) * HOURS * Ei

Where:

MotorHP = Rated horsepower of electric motor, summed when pumps are in series.

= Actual

%MotorLoading = Is dependent upon many factors including the part being manufactured, the polymer, the machine's specifications, and cycle time.

= Actual, calculated as (Average load / Full rated load)

= Estimated as 75%.[1937]

µMotor = Motor efficiency

= Actual. If unknown, estimated as 92% for motors in size range typically used.[1938]

HOURS = Hours of operation per year

= Actual

Ei = Efficiency improvement due to use of energy efficient hydraulic oils

= Actual. If not measured, assume 1% per gear mesh.[1939]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

N/A

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

O&M savings from the necessary standard oil replacement over the lifetime of the energy efficient gear oil (including oil cost, disposal costs, labor and avoided downtime) should be calculated. If additional savings for improved gear box lifetime can be demonstrated, these can also be included.

[1937] Most electric motors are designed to run at 50% to 100% of rated load, from Department of Energy "Determining Electric Motor Load & Efficiency", June 23, 2020.

[1938] Based on common size and type of motor - chart on pages 13-14, "Attachment C" of reference 9, the efficiency of a 50HP motor (TEFC type) at 1200 RPM is 92%. Or 75HP at 900 RPM at 75% TEFC type is 91.8%. These are common sizes and type for manufacturers.

[1939] Estimate based on review of a number of studies provided by ExxonMobil and saved in reference folders.

MEASURE CODE: CI-MSC-EEGL-V01-210101

REVIEW DEADLINE: 1/1/2023

4.9.19 Smart Sockets

DESCRIPTION

Smart sockets achieve savings through the reduction of the standby load of the controlled appliance, as well as eliminating the operation of an appliance during unoccupied hours. The standby power consumption of home appliances and office equipment can be significantly reduced.

In a commercial office space, significant opportunity exists for savings from the reduction of plug loads, with power strips and timers being a key energy saving measure.[1940] Savings from smart sockets generally occurs during off-hours, when connected equipment continues to consume electricity while in standby mode or when off. Savings may also be achieved through the more precise scheduling of the appliance, so that it is not operating during unoccupied hours, though those savings have not been attempted to be quantified within this summary.

Smart sockets are ideal for all types of plugged-in devices such as small appliances (coffee maker, office heater, etc.), in-wall AC units, large office equipment, outlet lights, digital signs, decorative lighting, televisions, etc, though they provide the greatest energy savings when installed on equipment with higher wattage and standby power consumption. In a commercial office space, the shared photocopier is often the largest stand-alone user of electricity, with the highest standby power draw, so an ideal candidate for use with a smart socket. Note that a dedicated power supply is critical for your office photocopier.[1941] Also, note that the electrical amperage rating of the smart socket should be verified to suit the connected equipment. Desktop computers with peripheral equipment may be better served by an advanced power strip.

This measure was developed to be applicable to the following program types: DI, KITS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is the use of a smart plug with a standby power wattage of 2W or less. Should be UL listed. (Simply Conserve Smart Socket SS-15A1-WiFi has a standby power of less than or equal to 0.7).

DEFINITION OF BASELINE EQUIPMENT

The assumed baseline is an appliance or piece of office equipment plugged into an outlet (without a power strip) or into a standard power strip with surge protection that does not control connected loads. Note many ENERGY STAR appliances require power saving settings which will partially offset the savings potential of this measure. Where possible non-ENERGY STAR equipment should be plugged in to the socket to ensure savings are realized.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of the smart socket is 7 years.[1942]

DEEMED MEASURE COST

For direct install, the actual full equipment and installation cost (including labor) and for kits the actual full equipment cost should be used. If unknown for kits, use $9.00/each.[1943]

[1940] See Page 6 of New Buildings Institute, "Plug Load Savings Assessment: Part of the Evidence-based Design and Operations PIER Program," California Energy Commission, Evidence-based Design and Operations PIER Program, March 2013.

[1941] From Ross Wiffler, "A Dedicated Power Supply is Critical for Your Office Copier", Copiers & More, Small Business, Aug. 18th, 2015. https://commonsensebusinesssolutions.com/a-dedicated-power-supply-is-critical-for-your-office-copier/

[1942] This is an assumption consistent with 4.8.7 Advanced Power Strip – Tier 1 Commercial.

[1943] Based on cost from vendor of typical smart socket on the market, Simply Conserve Smart Socket by AM Conservation Group. 10 amp smart socket: $8.92/each; 15 amp smart socket: $9.00/each.

LOADSHAPE

Loadshape C47 – Standby Losses – Commercial Office[1944]

COINCIDENCE FACTOR

N/A due to no savings attributable to standby losses between 1 and 5 PM.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

ΔkWh[1945] = ((((W$_{Base}$ * OnAdj) – W$_{Eff}$) * (hrs$_{wkday}$ - hrs$_{wkday\text{-}open}$)) + (((W$_{Base}$ * OnAdj)– W$_{Eff}$) * (hrs$_{wkend}$ - hrs$_{wkend\text{-}open}$))))/1000 * weeks/year * ISR

Where:

W$_{Base}$ = Standby power or On power consumption of connected appliance.

Use actual if known, or refer to tables below. If unknown, e.g. via kits, assume 9.4W[1946]

Appliances assumed to be in standby mode:

Controlled Equipment[1947]	Standby Power (W)
Coffee Maker	1.14
Television, CRT	3.06
Television, Rear Projection	6.97
Television, LCD[1948]	8.00
Set-top Box, DVR	36.68
Set-top Box, Digital Cable	17.83
Set-top Box, Satellite	15.66
Television/VCR	5.99
VCR	4.68
Computer, Desktop	2.84
Computer Notebook	8.90
Multifunction Device, Inkjet	5.26
Multifunction Device, Laser	3.12

[1944] As referenced in 4.8.7 Advanced Power Strip – Tier 1 Commercial, Loadshapes were calculated from empirical studies and compared to the existing loadshape in Volume 1, Table 3.5. The studies were:
Acker, Brad *et. al,* "Office Space Plug Load Profiles and Energy Saving Interventions," 2012 ACEEE Summer Study on Energy Efficiency in Buildings.
Sheppy, M. *et al*, "Reducing Plug Loads in Office Spaces" Hawaii and Guam Energy Improvement Technology Demonstration Project, NREL/NAVFAC (January 2014).

[1945] Savings algorithm reconstructed from weekday and weekend savings information in Acker, Brad *et. al,* "Office Space Plug Load Profiles and Energy Saving Interventions," 2012 ACEEE Summer Study on Energy Efficiency in Buildings, and verified against savings in Acker *et. al* and savings in: BPA, "Smart Power Strip Energy Savings Evaluation: Ross Complex," (2011). Office stations are assumed to have zero or minimal standy losses during normal operating hours. Method shown in "Commercial Tier 1 APS Calculations – IL TRM.xlsx".

[1946] Average connected wattage found in Guidehouse, 'ComEd Small Business Kits CY2020 Impact Evaluation Report 2021-04-01 Final.pdf'.

Controlled Equipment[1947]	Standby Power (W)
Scanner, Flatbed	2.48

Appliances assumed to be in on mode:

Controlled Equipment[1949]	On Power (W)
Light	10.4
Fan	70
Space Heater	450
Water Cooler	100

OnAdj = Adjustment for wattages of appliances that are powered on during out of hours

= 50%[1950] for appliances in on mode

=100% for appliances in standby mode and for unknown

W_{Eff} = Standby power consumption of smart socket. If unknown, assume 0.7W[1951].

hrs_{wkday} = total hours during the work week (Monday 7:30 AM to Friday 5:30 PM)

= 106

hrs_{wkend} = total hours during the weekend (Friday 5:30 PM to Monday 7:30 AM)

= 62

$hrs_{wkday\text{-}open}$ = hours the office is open during the work week. If unknown, assume 48 hours.

$hrs_{wkend\text{-}open}$ = hours the office is open during the weekend. If unknown, assume 10 hours. [1952]

weeks/year = number of weeks per year

= 52.2

ISR = In Service Rate

= Assume 0.969 for commercial Direct Install application[1953]

= Assume 0.28 for kits that include two smart sockets[1954]

= Assume 0.36 for kits that include one smart socket[1955]

[1949] See Standby Power Summary Table contained in "Standby Power", Lawrence Berkeley National Laboratory, Building Technology and Urban Systems Division, https://standby.lbl.gov/data/summary-table/

[1950] In the absence of empirical data, a 50% adjustment for appliances assumed to be on during out of hours is applied.

[1951] Average smart socket wattage found in Guidehouse, 'ComEd Small Business Kits CY2020 Impact Evaluation Report 2021-04-01 Final.pdf'.

[1952] Unknown hours are based on a Guidehouse review of open hours for 487 participants in this measure.

[1953] Based upon review of the PY2 and PY3 ComEd Direct Install Residential program surveys. This value could be modified based upon commercial application evaluation.

[1954] This ISR is based on the results of surveys of ComEd Small Business Kit recipients conducted in the Spring of 2021. This result includes the reduction in the installation rate from the survey respondents that indicated they did not install the application which is necessary to use the smart socket as intended.

[1955] This ISR is based on the results of the surveys of ComEd Small Business Kit recipients conducted in the Spring of 2021. It is based on an estimate of what the ISR would be if the kit only included a single socket even though all the kits distributed by ComEd included two sockets. Similar to the ISR for the two socket kits, this ISR accounts for the reduction in the installation rate from the survey respondents that indicated they did not install the application which is necessary to use the smart socket as intended.

For example, a smart socket is direct installed with a LCD Television in an office open 9.6 hours per day (48 hours per week) on weekdays and 10 hours on weekends:

ΔkWh = ((((8 * 1) – 0.7) * (106 - 48)) + (((8 * 1) – 0.7) * (62 - 10)))/1000 * 52.2 * 0.969

= 40.6 kWh

4.9.20 Lithium Ion Fork Truck Batteries

DESCRIPTION

This measure applies to electric fork trucks used in commercial, industrial, and warehouse environments. Electric fork trucks with lithium ion battery systems are more efficient than electric fork trucks with traditional lead acid battery systems because the lithium ion batteries have lower internal resistance. This allows the batteries to transfer power faster, reduces waste heat, and reduces standby losses.

Electric fork trucks can be purchased with lithium ion battery systems or an existing electric fork truck can be retrofitted to use a lithium ion battery system. An electric fork truck can be converted to a lithium ion battery system by removing the lead acid battery and installing a battery case that includes a series of lithium ion batteries and the appropriate ballast to meet weight and balance specifications for the fork truck. The lithium ion battery case is a one-for-one equivalent replacement of the lead acid battery in respect to capacity, shape, and weight. The fork truck may require a new charger to work with the new lithium ion battery system. Electric fork trucks can also replace propane or diesel powered fork truck in a one to one scenario. Where a facility normally operates a fleet of fossil-fueled fork trucks a fossil-fuel baseline should be considered for any additional fork trucks that might be purchased beyond the current quantity of trucks operating at the facility.

This measure was developed to be applicable to the following program types: TOS and RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Class I, Class II, or Class III fork trucks that are powered by lithium ion batteries with minimum 8-hour shift operation five days per week.

DEFINITION OF BASELINE EQUIPMENT

Class I, Class II, or Class III fork trucks that are powered by lead acid batteries or fossil-fuels such as propane or diesel with minimum 8-hour shift operation five days per week.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

15 years.[1956]

DEEMED MEASURE COST

Costs will vary significantly based on the capacity and class of the fork truck. Costs for this measure should be determined by actual quotes obtained from manufacturers and estimated labor. If not available, it is estimated that a new lithium ion fork truck would cost $34,400 compared with $17,200 for a new lead-acid battery fork truck, $24,200 for a propane and $25,100 for a diesel fork truck.[1957]

Converting a lead acid battery fork truck to a lithium ion battery system would cost $17,000.[1958]

LOADSHAPE

Loadshape C14 - Indust. 1-shift (8/5) (e.g., comp. air, lights)

Loadshape C15 - Indust. 2-shift (16/5) (e.g., comp. air, lights)

[1956] Lifetime of measure assumed to be limited by the lifetime of the lithium ion charger. See reference file Suzanne Foster Porter et al., "Analysis of Standards Options for Battery Charger Systems", (PG&E, 2010), 45.

[1957] Estimates for new lithium ion, propane and diesel from Dennis, Allen and Vairamohan, Bashkar. "EPRI Forklift (Lift Truck) Comparison with Capital Costs." Electric Power Research Institute. Accessed April 19, 2022. https://et.epri.com/ForkliftCalculator.html. A new lead-acid battery is estimated to be approximately half the cost of a lithium ion, as suggested in Thomas, Pete. "Is a Lithium Ion Forklift Battery Worth the Extra Expense?" Toyota Material Handling Northern California. https://www.tmhnc.com/blog/lithium-ion-forklift-battery-cost-and-runtime.

[1958] Thomas, Pete. "Is a Lithium Ion Forklift Battery Worth the Extra Expense?" Toyota Material Handling Northern California. Accessed May 5, 2021. https://www.tmhnc.com/blog/lithium-ion-forklift-battery-cost-and-runtime.

Loadshape C16 - Indust. 3-shift (24/5) (e.g., comp. air, lights)

Loadshape C17 - Indust. 4-shift (24/7) (e.g., comp. air, lights)

COINCIDENCE FACTOR

It is assumed that lead acid battery fork trucks are charged overnight. Therefore, the coincidence factor is assumed to be 0.0 for 1-shift and 2-shift operations and 1.0 for 3-shift and 4-shift operations.[1959]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS AND FOSSIL FUEL SAVINGS

Non-fuel switch (baseline of lead-acid fork truck):

$$\Delta kWh = (CAP * DOD * CHG * (1/ EE_{LAB} - 1/EE_{LIB})$$

Where:

CAP = Capacity of Battery

= Use actual battery capacity, otherwise use a default value of 35 kWh[1960]

DOD = Depth of Discharge

= Use actual depth of discharge, otherwise use a default value of 80%.[1961]

CHG = Number of Charges per year

= Use actual number of annual charges, if unknown use values below based on the type of operation

Standard Operations	Number of Charges per year
1-shift (8 hrs/day – 5 days/week)	520
2-shift (16 hrs/day – 5 days/week)	1,040
3-shift (24 hrs/day – 5 days/week)	1,560
4-shift (24 hrs/day – 7 days/week)	2,184

EE_{LAB} = Energy Efficiency of Lead Acid Battery

= Use actual efficiency of battery for retrofit, for new or unknown use 46%[1962]

EE_{LIB} = Energy Efficiency of Lithium Ion Battery

= Use actual efficiency of battery, if unknown use 73%[1962]

[1959] Matley, Ryan. May 29, 2009. "Industrial Battery Charger Energy Savings Opportunities." Emerging Technologies Program Application Assessment Report #0808. Pacific Gas & Electric.

[1960] Renquist, Jacob V., Brian Dickman, and Thomas H. Bradley. June 19, 2012. "Economic comparison of fuel cell powered forklifts to battery powered forklifts." International Journal of Hydrogen Energy, Volume 37, Issue 17.

[1961] Matley, Ryan. May 2009. "Measuring Energy Efficiency Improvements in Industrial Battery Chargers." Energy Systems Laboratory.

Fuel switch measures (baseline of propane or diesel fork truck):

Fuel switch measures must produce positive total lifecycle energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows (note for early replacement measures the lifetime savings should be calculated by calculating savings for the remaining useful life of the existing equipment and for the remaining measure life):

$$\Delta SiteEnergySavings\ (MMBtu) = (CAP * DOD * CHG * (1/EE_{BASE} - 1/EE_{LIB})) * 3{,}412/1{,}000{,}000$$

Where:

EE_{BASE}	= Energy efficiency of baseline fork truck. If unknown, assume the efficiency values below based on the type of fork truck. [1963]
	= 20.4% for Propane
	= 20.5% for Diesel
3,412	= Btu per kWh
1,000,000	= Btu per MMBtu

If SiteEnergySavings calculated above is positive, the measure is eligible.

Calculate savings as follows:

$$\Delta kWh = \Delta SiteEnergySavings * 1{,}000{,}000 / 3{,}412$$

Savings for each shift operation and baseline technology type using defaults provided above are provided below:

Standard Operations	Lead Acid	Diesel		Propane	
	Δ Elec (kWh)	ΔSiteEnergy Savings (MMBtu)	ΔSiteEnergy Savings (ΔkWh)	ΔSiteEnergy Savings (MMBtu)	ΔSiteEnergy Savings (ΔkWh)
1-shift (8 hrs/day – 5 days/week)	11,707	174	51,079	175	51,427
2-shift (16 hrs/day – 5 days/week)	23,414	349	102,158	351	102,855
3-shift (24 hrs/day – 5 days/week)	35,121	523	153,238	526	154,282
4-shift (24 hrs/day – 7 days/week)	49,169	732	214,533	737	215,995

SUMMER COINCIDENT PEAK DEMAND SAVINGS

It is assumed there is zero peak demand savings.

[1963] Dennis, Allen and Vairamohan, Bashkar. "EPRI Forklift (Lift Truck) Comparison with Capital Costs." Electric Power Research Institute. Accessed April 19, 2022. https://et.epri.com/ForkliftCalculator.html. Tank-to-wheel efficiency is based on dividing output electricity by input propane energy, assuming HHV of 91,333 BTU/gallon for propane and 138,500 BTU/gallon for diesel.

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

Lithium ion batteries offer several O&M advantages over lead acid batteries. These benefits include, but are not limited to:

- Lithium ion batteries charge must faster, which results in less downtime.[1964]
- There is no requirement for changing out batteries at the end of a shift or having multiple spare batteries in stock.[1964] A 3-shift operation would require a facility to have three separate lead acid batteries for each fork truck, so they could swap out batteries at the end of each shift. A lithium ion battery is charged while still in the fork truck and can use opportunity charging during employee breaktime.
- Fewer maintenance issues and no requirement for battery watering[1964]
- Longer operating life.[1965] Lithium ion batteries can last nearly four times as long as lead acid batteries.

These benefits should be considered and evaluated on a project-by-project basis. It is estimated that lithium ion fork truck adoption saves a facility 65 labor hours per truck on an annual basis.[1966]

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below) adjusted for utility line losses (at-the-busbar savings), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, this will not match the output of the calculation/allocation methodology presented in the "Fuel Switch Measures" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = [Fossil Fuel Consumption Saved]

= [CAP * DOD * CHG * EE_{LIB}/EE_{BASE} * 3412/100,000]

ΔkWh = [Electric Consumption Added]

= - [CAP * DOD * CHG]

4.9.21 Building Operator Certification

DESCRIPTION

Building Operator Certification (BOC) is a training and certification program for commercial and public sector building operators. The curriculum teaches participants how to improve building comfort and efficiency by optimizing the building's systems. BOC curriculums provide participants with knowledge about system operations, proper maintenance practices, occupant communication, and occupant comfort. Participants realize energy savings by utilizing the knowledge gained to improve their building operations through O&M and capital measures.

Evaluators in Illinois used differing levels of engagement with participants to estimate savings from the BOC training. While deeming savings does not fully capture the individual and varied actions that participants made as a result of their BOC training, it is a reasonable approach to better align the expected level of impacts and program expenditures with evaluation expenditures. Deemed savings for this measure represent a weighted average of analyses' results from several Illinois BOC program evaluations. The evaluations estimated net savings and were developed per square foot of building area to account for the diversity of building sizes across Illinois. All savings estimating algorithms presented in this work paper are for net savings. Participants are required to complete a rigorous BOC course and can only claim savings for the facilities for which the individual taking the course are responsible.

The 2023 IL-TRM v11.0 will be used to verify savings for 2021 and 2022 participants, and these results will be included in the final 2022 BOC evaluations (produced by April 30, 2023). This will include 2 years' worth of participants due to the annualization of savings for 2022 participants and the transition year of 2021 to the deemed approach.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is facilities operated by participants who complete a BOC training program. Participants must complete either the BOC Level I or Level II course and obtain a certificate of completion to be eligible for savings[1967]. Eligible BOC programs must cover the following subject areas:

BOC Level I

- Efficient Operation of HVAC Systems
- Measuring and Benchmarking Energy
- Efficient Lighting Fundamentals
- HVAC Controls Fundamentals
- Indoor Environmental Quality
- Common Opportunities for Low-Cost Operational Improvement

BOC Level II

- Building Scoping and Operational Improvements
- Optimizing HVAC Controls for Energy Efficiency
- Introduction to Building Commissioning
- Water Efficiency for Building Operators
- Project Peer Exchange

The BOC course must include formal instruction (i.e., lectures), individual projects and group exercises, bringing the total course time to at least 61 hours. Participants must obtain a training certificate of completion to be eligible for savings. Individuals who participate are not eligible for savings more than twice over the measure life, once for BOC Level I and another for BOC Level II. The entire floor area for any given building can only be used once over the measure life, and evaluators will verify attendees' participation year-over-year.

The savings factors for this measure were developed based on an examination of savings using a weighted average approach from several similar BOC programs. The table below outlines the referenced evaluation studies, and key

[1967] Future evaluation research could explore savings differences between Level I and Level II participants.

parameters which were inputs to this measure characterization. It is important to note that the savings information referenced is net. Therefore, this measure does not require the additional application of a net-to-gross ratio.

No previous custom study of customer participation in BOC shall inform eligibility for this measure.

Utility or Program Administrator	Year	Participants	Average Building Area	MWh/ Participant	kW/ Participant	Therm/ Participant	Incremental Measure Costs ($/Participant)[1968]
Ameren Illinois[1969]	2020	10	140,137	60.002	0.83	987	$253.94
Ameren Illinois[1970]	2019	12	408,309	64.421	12.80	3,615	$114.93
Ameren Illinois[1971]	2021	8	502,944	23.650	0.00	0	$0.00
ComEd[1972]	2020	33	319,068	132.600	14.70	N/A	$8,878.79
ComEd[1973]	2021	2	517,250	20.755	1.55	N/A	$9,310.50
Nicor Gas[1974]	2021	3	517,250	0.000	0.00	234	$0.00
Weighted Average[1975]			344,708	91.994	10.00	1,635	$4,640.29

DEFINITION OF BASELINE EQUIPMENT

The baseline is building operations as they existed before the participant completed the BOC training course.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for BOC savings is 13 years[1976]. Based on analyzed research, assume 42%[1977] of BOC savings are derived from O&M measures that have a 4-year measure life[1978]. This should be handled similar to other midlife adjustments, where after 4 years, a midlife adjustment factor of 58% is applied for the remaining nine years of the measure life.

[1968] Total incremental measure costs from the evaluation, net of O&M adjustments (if applicable), divided by the number of BOC participants.
[1969] Opinion Dynamics, 'Ameren Illinois Company 2020 Business Program Impact Evaluation Report, Final', April 28th 2021.
[1970] Opinion Dynamics, 'Ameren Illinois Company 2019 Business Program Impact Evaluation Report, Final', April 30th 2020.
[1971] Opinion Dynamics, 'Ameren Illinois Company 2019 Business Program Impact Evaluation Report, Final', April 29th 2022.
[1972] The ComEd evaluation includes both 2018 and 2019 participants. The interview sample did not stratify by program year, so the savings per participant are the same for each year. Guidehouse, 'ComEd Building Operator Certification Pilot Impact Evaluation Report', April 12th, 2021.
[1973] Guidehouse, 'ComEd Building Operator Certification Pilot Impact Evaluation Report', April 19th, 2022.
[1974] Guidehouse completed follow-up interviews with 2018 – 2020 participants from ComEd's program which also had gas service. Three interviews were completed, and all were Nicor Gas customers who completed no cost scheduling and usage tracking. The savings for these participants was calculated following the methodology used to determine the savings for ComEd's CY2022 Building Operator Certification Pilot.
[1975] The weighted average numbers are used to determine the savings parameters within this measure. The savings parameters are set so the participated weighted average savings using the TRM algorithm, including the building area cap, equals the participant weighted average savings from the referenced evaluation studies.
[1976] Average measure life of capital measures from the ComEd CY2020 evaluation.
[1977] Weighted average from referenced evaluation studies which outlined lifetime information.
[1978] EUL for operational updates when the controls type is unknown. See Attachment B:Effective Useful Life for Custom Measure. Effective Useful Life for Retro-commissioning and Behavior Programs memo by Guidehouse, September 17, 2019.

DEEMED MEASURE COST

The deemed training measure cost is $1,695.[1979] In addition, the incremental cost of capital and O&M measures should also be included. If unknown, use an incremental measure cost of $0.014/ft^2.[1980]

LOADSHAPE

C23 – Commercial Ventilation

COINCIDENCE FACTOR

The demand savings factor (C_d) is already based upon coincident savings, and thus there is no additional coincidence factor for this characterization.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = C_e * Area$$

Where

Area = Building area operated by the participant. The maximum eligible area per participant is 500,000 ft^2. In the event there are multiple participants who operate the same building (i.e. service address), or group of buildings, the program administrator can only claim savings on building square footage once (i.e., they cannot claim savings based on the same square footage for multiple participants), unless the managed square footage exceeds 500,000 ft^2; in which case, the program administrator can continue to claim savings up to the 500,000 ft^2 per participant cap until the total square footage has been accounted for.

C_e = unit area kWh savings constant per participant[1981], 0.274 kWh/ft^2/participant

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$kW = C_d * Area / 1000$$

Where

C_d = Unit demand savings constant[1982], 0.03 W/ft^2 (capped)/participant

1000 = unit conversion from W to kW

FOSSIL FUEL SAVINGS

$$Therms = C_g * Area$$

4.9.22 Warm-Mix Asphalt Chemical Additives

DESCRIPTION

Warm-Mix Asphalt (WMA) is the name for a variety of technologies that allow for production and placement of asphalt at temperatures lower than traditional Hot-Mix Asphalt (HMA). The production temperature of WMA is typically 25°F to 90°F below that of HMA, resulting in reduced energy consumption. The actual temperature reduction depends upon the warm mix technology used. Currently, there are three categories of WMA technologies: asphalt foaming technologies, organic additives, and chemical additives.

The asphalt foaming technologies include a variety of processes to foam asphalt, including water-injecting systems, damp aggregate, or the addition of a hydrophilic material such as a zeolite. In the asphalt plant, the water turns to steam, disperses throughout the asphalt, and expands the binder, providing a corresponding temporary increase in volume and fluids content, similar in effect to increasing the binder content. Chemical additives often include surfactants that aid in coating and lubrication of the asphalt binder in the mixture. Lastly, organic additives are typically special types of waxes that cause a decrease in binder viscosity above the melting point of the wax.

In additional to energy savings, using WMA in place of HMA reduces greenhouse gas emissions and provides multiple non-energy benefits, such as beter compaction, cool-weather paving, longer haul distances, and improved working conditions for the paving crew (reduction of fumes and odors). Warm-mix chemical additives allow for the mixing and placement of asphalt at temperatures lower than traditional HMA while maintaining similar strength, durability, and performance characteristics.

This measure is applicable to the industrial market with the end user in the transporation sector. WMA can be used in any climate, as the lower mix temperature allows WMA to be used in cooler ambient conditions than traditional HMA.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is WMA. WMA is generally produced at temperatures ranging from 25°F to 90°F lower than HMA.[1984]

General WMA technologies can be categorized as chemical additives, organic additives, and water-based foaming methods. Chemical additives reduce the internal friction between aggregate particles and thin films of binders when subjected to high shear rates during mixing and high shear stress during compaction. In contrast, the other two WMA methods rely on reduction of binder viscosity.

DEFINITION OF BASELINE EQUIPMENT

The baseline case is traditional HMA. HMA is traditionally mixed between 280°F and 320°F.[1985]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is 1 year. Savings occur during production, and last only as long as the production runs. Since savings and costs scale to tons of asphalt production, a 1-year measure life appropriately tracks lifecycle savings.

[1984] West, R.C., M.C. Rodezno, G. Julian, B.D. Prowell, B. Frank, L.V. Osborn, & A.J. Kriech (2014). "NCHRP Report 779:Field Performance of Warm-Mix Asphalt Technologies. Transportation Research Board of the National Academies", Washington, D.C. doi:10.17226/22272.

[1985] West, R.C., M.C. Rodezno, G. Julian, B.D. Prowell, B. Frank, L.V. Osborn, & A.J. Kriech (2014). "NCHRP Report 779:Field Performance of Warm-Mix Asphalt Technologies. Transportation Research Board of the National Academies", Washington, D.C. doi:10.17226/22272.

DEEMED MEASURE COST

The costs of WMA depend primarily on the type of WMA technology that is used. Of the WMA technology options, water-injection asphalt foaming typically have the lowest cost per ton. Water injection WMA technologies have a lower incremental cost at around $0.08 per ton.[1986]

Compared to other WMA technologies, additive based WMA technologies increase the mix costs by $2.50 per ton[1987] due to the cost of chemicals and freight costs.

LOADSHAPE

N/A

COINCIDENCE FACTOR

N/A

Algorithm

CALCULATION OF ENERGY SAVINGS

Energy savings are dependent on multiple factors that primarily affect the production of WMA. The following factors have been identified as the primary contributors to energy consumption:

- Mixing drum temperature
- Additive type

ELECTRIC ENERGY SAVINGS

N/A.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A.

FOSSIL FUEL SAVINGS

Average temperature reduction achieved by plants that reduce mix production temperature when using WMA must be determined to estimate reductions in energy consumption. In practice, WMA production temperatures when using water-injection foaming technologies are typically about 25°F lower than those for hot mix asphalt (HMA) using the same mix design. WMA produced with additives tends to have substantially lower mixing temperatures. For the purpose of estimating energy savings, a temperature difference of 50°F is assumed for additive-type WMA compared to HMA using the same mix design.

$$therms_{savings} = tons \times SF$$

Where:

tons = Tons of asphalt produced

SF = WMA production savings factor (therms/ton)

= See Table for SF for Water Injection Foaming and Additives

[1986] West, R.C., M.C. Rodezno, G. Julian, B.D. Prowell, B. Frank, L.V. Osborn, & A.J. Kriech (2014). "NCHRP Report 779:Field Performance of Warm-Mix Asphalt Technologies. Transportation Research Board of the National Academies", Washington, D.C. doi:10.17226/22272.

[1987] West, R.C., M.C. Rodezno, G. Julian, B.D. Prowell, B. Frank, L.V. Osborn, & A.J. Kriech (2014). "NCHRP Report 779:Field Performance of Warm-Mix Asphalt Technologies. Transportation Research Board of the National Academies", Washington, D.C. doi:10.17226/22272.

Energy Savings by mixing temperature reduction

WMA Production Technology	[A] Energy Savings [1988] (therms/Δ°F/ton)	[B] Temperature Reduction (°F)	[C] = [A]*[B] SF (therms/ton)
Water Injection Foaming	0.011	25	0.275
Additives	0.011	50	0.55
Custom Documented	0.011	Custom	Calculated

Example:

A plant producing 1,000 ton ashphalt everyday now decides to adopt additives for energy savings and non energy benefits. The savings for that plant will be computed:

Savings = 1,000 tons * 0.55 (therms/ton)

= 550 therms saved.

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

In addition to reduced energy consumption, reduction in production temperatures results in reduced greenhouse gas emissions from the combustion process and any emissions from the mixed asphalt. The reduction of emissions, fumes, and odors results in a healthier work environment for production operators, truck drivers, and application workers. The lower temperature mix also allows for an extended paving season, night paving, and longer hauling distances for the WMA in comparison to HMA with faster application times.

4.9.23 Energy Efficient Hand Dryers

DESCRIPTION

This measure consists of installing efficient hand dryers that save energy by drying with air movement, using motion sensors, and reducing drying time. Energy efficient hand dryers use less energy per dry than standard hand dryers. Hand dryers are applicable in retail, commercial, and industrial settings.

This measure was developed to be applicable to the following program types: TOS, ERET. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, a hand dryer must be motion operated with rated load of 1,500 W or less.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment for this measure is a push-button operated hand dryer with connected load in excess of 1,500 Watts.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for a new energy efficient hand dryer is 10 years[1989].

DEEMED MEASURE COST [1990]

Incremental cost is $483. Baseline cost for a hand dryer is $368. Efficient cost for an efficient hand dryer is $851.

LOADSHAPE

Loadshape C02 - Commercial Electric DHW

COINCIDENCE FACTOR

Formula of Coincidence Factor is as follows:

$$CF = \frac{Cycle\ Time\ per\ Use * Use\ per\ Day * Site\ Occupied\ Days\ per\ Year}{Site\ Occupied\ Hours\ per\ Day * 365}$$

[1989] Based on studies conducted by two separate parties; Comparative Environmental Life Cycle Assessment of Hand Drying Systems by Quantis (pg 2) and Guidelines to Reduce/Eliminate Paper Towel Use by Installing Electric Hand Dryers by Partners in Pollution Prevention P3 (pg 17).

[1990] Cost is the average retail costs for 16 baseline and 10 efficient hand dryers. See *Hand_Dryer_Analysis.xlsx* . Cost source: RestroomDirect.com

Where:

Usage	Example Building Types	Cycles per Day[1991]	Occupied Days per Year (DPY)[1992]	Occupied Hours per Day[1993]	Coincidence Factor (CF)
Low	Office, Warehouse	50	250	8	0.04
Moderate	Restaurant, Small Grocery, Small Retail	125	365	15	0.09
High – <12 hr/day	K-12 School, University, Theater, Conference Center	250	200	9	0.16
High – >=12 hr/day	Large Grocery, Retail Department Store	375	365	13	0.29
Heavy - Intermitent	Stadium, Theater, Place of Worship	250	80	6	0.10
Heavy Duty - 24/7	Transportation Center, Airport	750	365	23	0.34

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = CPD * DPY * \frac{(Watts_{Base} * CycleTime_{Base} - Watts_{EE} * CycleTime_{EE})}{(3600\ \frac{sec}{hr} * 1000\ \frac{Watts}{kW})}$$

Where:

CPD = Number of cycles per day.

= If not known, use assumption as defined in Coincidence Factor section.

DPY = Number of days the facility operates per year.

= If not known, use assumption as defined in Coincidence Factor section.

Watts = Unit wattage.

= Actual. If not known, use assumption from the table below.

Assumptions	Power (watts)
Baseline[1994]	2,036
Efficient[1995]	1,066

[1991] *Guidehouse, Inc. Engineering Estimate, 2022*

[1992] *Illinois TRM v9.0, Days per year, from 4.3.2 Low Flow Faucet Aerators*

[1993] *Occupancy based on Lighting HOU from Section 4.5, combined with days per year from Section 4.3.2.*

[1994] CLEAResult survey of 24 hand dryers in convenience stores in Arkansas. See *Hand_Dryer_Analysis.xlsx*.

[1995] CLEAResult cost/specification survey of 10 unique efficient hand dryers. See *Hand_Dryer_Analysis.xlsx*.

Cycle Time = Runtime seconds per use.

= Actual. If not known, use assumption from the table below.

Assumptions	Cycle Time (seconds)
Baseline[1996]	37
Efficient[1997]	12

For example, a new efficient hand dryer replacing a baseline hand dryer at a large grocery store, with unknown cycles per day and unknown days per year:

ΔkWh = (375 * 365 * (2,036*37 - 1,066*12) / (3600*1000)
= 2378 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta\text{kW_Peak} = \frac{(Watts_{Base} - Watts_{EE})}{1000} * CF$$

Where:

$Watts_{Base}$ = As defined in section above.

$Watts_{EE}$ = As defined in section above.

CF = Coincidence Factor as defined in Coincidence Factor section (shown here for convenience):

$$CF = \frac{Cycle\ Time\ per\ Use * Use\ per\ Day * Site\ Occupied\ Days\ per\ Year}{Site\ Occupied\ Hours\ per\ Day * 365}$$

Where:

[1996] CLEAResult survey of 24 hand dryers in convenience stores in Arkansas. See *Hand_Dryer_Analysis.xlsx*.
[1997] CLEAResult cost/specification survey of 10 unique efficient hand dryers. See *Hand_Dryer_Analysis.xlsx*.

Usage	Example Building Types	Cycles per Day[1998]	Occupied Days per Year (DPY)[1999]	Occupied Hours per Day[2000]	Coincidence Factor (CF)
Low	Office, Warehouse	50	250	8	0.04
Moderate	Restaurant, Small Grocery, Small Retail	125	365	15	0.09
High – <12 hr/day	K-12 School, University, Theater, Conference Center	250	200	9	0.16
High – >=12 hr/day	Large Grocery, Retail Department Store	375	365	13	0.29
Heavy - Intermitent	Stadium, Theater, Place of Worship	250	80	6	0.10
Heavy Duty - 24/7	Transportation Center, Airport	750	365	23	0.34

For example, a new efficient hand dryer replacing a baseline hand dryer at a large grocery store, with unknown cycles per day and unknown days per year:

ΔkW = ((2,036 – 1,066)/1000)*0.29
= 0.28 kW

4.9.24 Elevator Modernization

DESCRIPTION

This measure covers the upgrade of existing elevators by replacing critical components in order for elevators to be able to handle new technology, have better performance, and to operate more efficiently. Elevator modernization typically includes motor upgrades, elevator drive system upgrades, and elevator controller replacement.

This measure is applicable to the following program types: RF.

DEFINITION OF EFFICIENT EQUIPMENT

This measure is applicable when retrofitting an existing Elevator with a Higher efficiency Motor/ Drive [Silicon Controlled Rectifier (SCR), Pulse Width Modulator (PWD) or variable Voltage variable frequency drive (VVVF)]/ Controller.

Only applicable to Office and Multifamily buildings (e.g.- small offices, large offices, low-rise multifamily, High-rise multifamily)

DEFINITION OF BASELINE EQUIPMENT

The baseline is existing elevator systems with lower efficiency Motor/ Drive [only listed drive system applicable: Motor-Generator (M-G) set system, Silicon Controlled Rectifier (SCR) and Pulse Width Modulator (PWD)]/ Controller.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected lifetime of the measure is 15 years.[2001]

DEEMED MEASURE COST

Costs are highly specific to each installation, as so the actual Equipment and Labor costs should be used.

LOADSHAPE

N/A

COINCIDENCE FACTOR

The coincidence factor for this measure is 1.0. Appling average load factor at peak is a conservative approach for estimating summer peak demand savings.[2002]

Algorithm

CALCULATION OF ENERGY SAVINGS

Only the following control upgrade configurations are applicable to this measure

Acceptable Elevator Drive Replacement Configuration

Baseline Condition	Compliance Condition
(M-G) Set	SCR, PWM, VVVF drives
SCR drive	PWM, VVVF drive
PWM drive	VVVF drive

[2001] New York Standard Approach for Estimating Energy Savings from Energy Efficiency Programs V11- End of Useful life, https://dps.ny.gov/system/files/documents/2023/12/nys-trm-v11_filing.pdf

[2002] New York Standard Approach for Estimating Energy Savings from Energy Efficiency Programs V11- ELEVATOR MODERNIZATION.

Methods for calculating savings for M-G set baseline systems are presented below separate from SCR or PWM drive baseline systems in order to differentiate the baseline efficiency term as described in the Baseline Efficiency section below, but also to account for AC motor idling energy consumption present in an M-G set drive. There is no idling motor present in PWM or SCR drive systems, and thus no savings associated with idle energy is claimed in those cases.

ELECTRIC ENERGY SAVINGS

Motor-Generator set (M-G) as baseline system:

$$\Delta kWh = units \times [\Delta kWh_{baseline} - \Delta kWh_{ee} + (RegenSF \times \Delta kWh_{regen})]$$

$$\Delta\text{kWh}_{baseline} = \left[\frac{lb_{baseline} \times (1 - OCW_{baseline}) \times (ft/min)_{baseline}}{33{,}000 \times Eff_{hoist}} \times \frac{1}{Eff_{baseline}} \times 0.746 \times LF_{avg} \times hrs\right] + \left[\frac{hp \times 0.746 \times LF_{motor,idle}}{Eff_{baseline}} \times (8{,}760 - hrs) \times F_{idle}\right]$$

$$\Delta\text{kWh}_{ee} = \frac{lb_{ee} \times (1 - OCW_{ee}) \times (ft/min)_{ee}}{33{,}000 \times Eff_{hoist}} \times \frac{1}{Eff_{ee}} \times 0.746 \times LF_{avg} \times hrs$$

$$\Delta\text{kWh}_{regen} = \frac{lb_{ee} \times (1 - OCW_{ee}) \times (ft/min)_{ee} \times 0.746 \times Eff_{ee}}{33{,}000} \times Eff_{regen} \times F_{regen} \times hrs$$

SCR drive or PWM drive as baseline system:

$$\Delta kWh = units \times [\Delta kWh_{baseline} - \Delta kWh_{ee} + (RegenSF \times \Delta kWh_{regen})]$$

$$\Delta\text{kWh}_{baseline} = \frac{lb_{baseline} \times (1 - OCW_{baseline}) \times (ft/min)_{baseline}}{33{,}000 \times Eff_{hoist}} \times \frac{1}{Eff_{baseline}} \times 0.746 \times LF_{avg} \times hrs$$

$$\Delta\text{kWh}_{ee} = \frac{lb_{ee} \times (1 - OCW_{ee}) \times (ft/min)_{ee}}{33{,}000 \times Eff_{hoist}} \times \frac{1}{Eff_{ee}} \times 0.746 \times LF_{avg} \times hrs$$

$$\Delta\text{kWh}_{regen} = \frac{lb_{ee} \times (1 - OCW_{ee}) \times (ft/min)_{ee} \times 0.746 \times Eff_{ee}}{33{,}000} \times Eff_{regen} \times F_{regen} \times hrs$$

where:

ΔkWh	= Annual electric energy savings
units	= Number of units upgraded under the program
$Eff_{baseline}$	= Baseline equipment's combined Efficiency. The baseline condition is an existing M-G set, SCR drive, or PWM drive elevator system. The efficiency of the baseline elevator drive systems is derived as follows: $Eff_{baseline} = Eff_{motor,\ baseline} \times Eff_{gear,\ baseline} \times Eff_{drive,\ baseline}$
$Eff_{motor,\ baseline}$	= Baseline motor efficiency (NEMA premium efficiency[2003])
$Eff_{drive,\ baseline}$	= Baseline drive efficiency, use actual if unknown use the values from Table below

Drive type	Efficiency[2004]
SCR 6	0.85
SCR12	0.90
PWM	0.94

[2003] Elevator Door Lock Monitoring & Energy Code Compliance presentation; Pg-19; https://www.nyc.gov/assets/buildings/pdf/Elevators_DLM_Energy_Code_Compliance.pdf, NY code Currently uses IE2 efficiency as code requirement.

[2004] Ibid, V11- ELEVATOR MODERNIZATION.

$Eff_{gear,\ baseline}$ = Baseline Gear efficiency, if the existing is Geared use 0.85 if not use 1.[2005]

Eff_{ee} = efficiency equipment's combined Efficiency. The compliance condition may be either Silicon-Controlled Rectifier (SCR) drive, Pulse Width Modulation (PWM) drive or Variable Voltage Variable Frequency (VVVF), Check the Calculation of energy savings section for acceptable replacement configuration.

$$Eff_{\text{ee}} = Eff_{motor,\ \text{ee}} \times Eff_{gear,\ \text{ee}} \times Eff_{drive,\ \text{ee}}$$

$Eff_{motor,\ ee}$ = New motor efficiency, use actual

$Eff_{drive,\ ee}$ = New drive efficiency, use actual if unknown use the values from Table below

Drive type	Efficiency[2006]
SCR 6	0.85
SCR12	0.90
PWM	0.94
VVVF	0.95

$Eff_{Gear,\ ee}$ = New Gear efficiency, if the existing is Geared use 0.85 if not 1.[2007]

Eff_{regen} = regenerative efficiency, if unknown use 0.5.[2008]

Eff_{hoist} = hoist system efficiency, if unknown use 0.90.[2009]

RegenSF = Savings Factor for regenerative braking system. If Regenerative Breaking used 1 if not use 0.

$lbs_{baseline}$ = Baseline Car capacity.

lbs_{ee} = New Car capacity.

$OCW_{baseline}$ = Overweight of counterbalance as a fraction of car capacity. If unknown use 0.50.[2010]

OCW_{ee} = Overweight of counterbalance as a fraction of car capacity. If unknown use 0.50. [2011]

ft/min = Rated top velocity of car, in ft/min

LF_{avg} = Average load factor. If unknown use 0.35.[2012]

hrs = Annual hours of elevator operation. If unknown use 2,750.[2013]

hp = Horsepower of M-G set motor

$LF_{motor,\ idle}$ = M-G set motor load factor in idling mode, 0.11 [2014]

[2014] Ibid, V11- ELEVATOR MODERNIZATION.

F_{idle} = Idling factor; used to account for fraction of run hours M-G set system in idling mode. Use the table below.

Description	Idling factor[2015]
Timer incorporated	0.7
No Timer	1
Unknown	0.7

F_{regen} = Regenerative breaking factor; used account for fraction of run hours regenerative braking produces energy savings. If unknown use 0.5[2016] (Regenerative braking eliminates excess heat and supplies electric energy to the building 50% of run time: when lightly loaded car is raised, when fully loaded car is lowered, whenever the car decelerates).

0.746 = Conversion factor (kW/hp) 0.746 kW equals one electric horsepower

8,760 = Annual hours

33,000 = Conversion factor ((ft-lb/min)/hp), 33,000 foot-pounds per minute equals one electric horsepower.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Motor-Generator set (M-G) as baseline system-

$$\Delta\text{kW} = \text{Unit} \times \left\{ \frac{hp \times 0.746 \times LF_{motor,run}}{Eff_{baseline}} - \frac{lb_{ee} \times (1 - OCW_{ee}) \times (ft/min)_{ee} \times 0.746 \times LF_{peak}}{33{,}000 \times Eff_{hoist} \times Eff_{ee}} \right\} * \text{CF}$$

With SCR drive or PWM drive as baseline system-

$$\Delta\text{kW} = \text{Unit} \times \left\{ \left[\frac{lb_{baseline} \times (1 - OCW_{baseline}) \times (ft/min)_{baseline}}{Eff_{baseline}} - \frac{lb_{ee} \times (1 - OCW_{ee}) \times (ft/min)_{ee}}{Eff_{ee}} \right] \times \frac{0.746 \times LF_{peak}}{33{,}000 \times Eff_{hoist}} \right\} * \text{CF}$$

Where:

$LF_{motor,\ run}$ = M-G set motor load factor when loaded

= 0.9.[2017]

LF_{peak} = Peak load factor

= 0.75.[2018]

CF = Summer coincident factor

= 1.0

MEASURE CODE: CI-MSC-EVMD-V01-250101

REVIEW DEADLINE: 1/1/2029

4.9.25 Virtual AMI Driven Commissioning

DESCRIPTION

This measure applies to non-residential operations and maintenance (O&M) related energy savings opportunities identified via statistical analysis of customer interval meter data. To qualify for this measure, the savings opportunities must be identified via statistical identification of the appropriate target population. Individual baseline models are created for the population of non-residential customer meters and the target population is identified by screening the population for goodness-of-fit of baseline models based on hourly advanced metering infrastructure (AMI) data. The goodness-of-fit criteria are developed using accepted industry-wide methods that conform to IPMVP or other industry protocols and documents. The method is described in the Lawrence Berkeley National Laboratory's Site-Level Normalized Metered Energy Consumption Technical Guidance document[2019].

Energy advisors perform an in-depth analysis and screening of interval AMI data and associated customer account information to identify opportunities. Examples of sites flagged for intervention are those with a low overall load factor (suggesting significant variance in energy usage patterns), customers whose interval level data displays a lot of variability in energy usage profiles for the same periods of day or from one day to the next, and sites that have participated in other utility DSM programs, among other factors. Once prospective individual accounts have been screened, the Energy Advisor will contact the customer to introduce the program, review whether the identified opportunity is legitimate based on information regarding their business operations, hours of operation, equipment or building information, and discuss suggested energy conservation measures (ECM) to achieve potential savings.

Post-implementation, for all sites (both above and below 8 GWh of annual consumption) each site's pre- and post-implementation AMI data is reviewed monthly to verify that the anticipated changes were implemented with an associated reduction in energy usage apparent in the site's AMI data as well as to monitor and ensure continued implementation of the changes for the duration of the relevant program year. This is done in tandem with automated modeling processes that evaluate projects throughout the week and flag issues with expected implementation through automated alerts.

For some buildings, irregular building operations or other factors may make it impossible to verify the existence or persistence of implemented changes in the site's AMI data, and in such cases the changes will not qualify for the measure. End of year changes will qualify based on Energy Advisor and customer confirmation of the change.

This measure was developed to be applicable to the following program types: Retrofit (RF). If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case refers to a non-residential building that has completed one or more of the following virtual AMI driven commissioning changes:

- Optimizing equipment schedules (including lighting and exhaust fans)
- Optimizing economizer operation
- Managing HVAC equipment start-up and shut-down schedules
- Identifying HVAC equipment setbacks to address unnecessary usage
- Managing HVAC equipment sequencing to address short cycling
- Optimizing occupied HVAC zone temperature setpoints to operate within building design parameters
- Optimizing chilled and hot water systems
- Lowering compressed air system pressure and/or identifying setbacks
- Resolving of major maintenance issues (e.g. compressed air system leaks)
- Optimizing other non-HVAC equipment operation (e.g. scheduling industrial equipment)

[2019] LBNL Site-Level NMEC Technical Guidance Version 2.0, section 2: Baseline model goodness of fit screening for the target population https://www.cpuc.ca.gov/-/media/cpuc-website/files/legacyfiles/l/6442463695-lbnl-nmec-techguidance-01072020.pdf

The non-residential building must have a utility meter providing hourly or more granular energy consumption.

DEFINITION OF BASELINE EQUIPMENT

The baseline case refers to a non-residential building where where an Energy Advisor reviewing the building's AMI data has observed one or more of the following energy use characteristics:

- Minimal change in energy consumption between suspected occupied and unoccupied periods.
- High energy consumption during suspected unoccupied periods.
- Other patterns in energy use that are not consistent with typical, efficient building operation (such as unexplained spikes or rapid oscillation in energy use which may suggest short cycling)

The non-residential building must have a utility meter providing hourly or more granular energy consumption.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

This measure reflects a combination of savings activities implemented via the building automation system, Strategic Energy Management (SEM), as well as remote and manual O&M related adjustments. The average EUL is assumed to be 7.3 years.[2020]

DEEMED MEASURE COST

The cost to the customer is $0, or very low. Study-based costs will be included in non-incentive costs for the utility program, so the incremental costs of the study-based survey will be included at the program level.

LOADSHAPE

Depending on the baseline conditions, the appropriate loadshapes may be a combination of some, but not all, of the loadshapes below.

Loadshape C02 – Commercial Electric DHW
Loadshape C03 – Commercial Cooling
Loadshape C04 – Commercial Electric Heating
Loadshape C05 – Commercial Electric Heating and Cooling
Loadshape C06 – Commercial Indoor Lighting
Loadshape C07 – Grocery/Conv. Store Indoor Lighting
Loadshape C08 – Health Indoor Lighting
Loadshape C09 – Office Indoor Lighting
Loadshape C11 – Retail Indoor Lighting
Loadshape C13 – Education Indoor Lighting
Loadshape C23 – Commercial Ventilation
Loadshape C54 – Religious Indoor Lighting

COINCIDENCE FACTOR

The measure has deemed coincident peak kW savings therefore a coincidence factor does not apply.

[2020] As defined in the IL-TRM through ComEd EUL Research (https://www.ilsag.info/wp-content/uploads/ComEd-EUL-Research-CY2020-Final-Outcomes-Virtual-Delphi-Panel-2020-12-18.pdf)

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = kWhbase * PES$$

Where:

ΔkWh = Energy savings for measure (in kWh)

kWhbase = Weather normalized, baseline annual energy use (in kWh)

= Actual [2021]

PES = Percentage energy savings[2022]

Change Type	Weather Normalized, Baseline Annual Energy Use (GWh/year)	Change Type*	PES[2023]
All Types	< 8 GWh	Annual Impact	15.1
		Cooling only	11.7
		Heating only	10.4
		Cooling & Heating	12.1
		Average/Unknown	**14.8**
	> 8 GWh	Use Custom M&V approach[2024]	

*Annual Impact: Changes providing savings year around, e.g. from lighting and ventilation schedules in addition to heating and cooling changes.

Heating: Changes providing savings in heating season only.

Cooling: Changes providing savings in cooling season only.

Cooling & Heating: Changes providing savings in heating and cooling season only, without additional year round savings.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = kWaverage * PDS$$

Where:

kWaverage = Weather normalized, average summer peak demand[2025] (in kW)

[2021] Calculated using a custom modelling approach, normalized to the appropriate TMY dataset.

[2022] The PES should be verified once per plan cycle via a full evaluation of Virtual AMI Driven Commissioning projects based on consumption analysis of project site meter data. This analysis will be used to determine if any updates to the savings assumptions are warranted.

[2023] Power TakeOff & Abacus Energy Works, Prescriptive Program Design for Virtual Commissioning® Using a Deemed Savings Approach, April 2025 & Econoler, Memo – Power TakeOff Virtual VCx Prescriptive Savings Estimate, January 2025. These values represent post evaluation % savings (incorporating an average ex post adjustment of 97.3%) and are adjusted to remove anticipated program cross-participation.

[2024] Following LBNL's Site-Level NMEC Technical Guidance document as referenced above, the custom M&V approach is assumed to follow IPMVP Option C: Whole Facility analysis, using regression modeling techniques, with outdoor air temperature, and time-of-week indicators as the key independent variables.

[2025] Average kW demand is calculated as: an hourly baseline model that is weather normalized (appropriate TMY dataset) and applied to Illinois specific peak hours and averaged across those hours.

PDS = Percentage demand savings[2026]

Change Type	Weather Normalized, Baseline Annual Energy Use (GWh/year)	PDS
Heating Only	n/a	0%
All Other Types	< 8 GWh	9.5%[2027]
	> 8 GWh	Use Custom M&V approach[2028]

FOSSIL FUEL SAVINGS

N/A. While fossil fuel savings can be expected from heating related activities in fossil heated buildings, with limited access to gas AMI data and with evaluations to date focused on electric savings, no prescriptive fossil fuel savings are provided. Programs should use a custom M&V approach if claiming fossil fuel savings.

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

5.1 Appliances End Use

5.1.1 ENERGY STAR Air Purifier/Cleaner

DESCRIPTION

An air purifier (cleaner) meeting the efficiency specifications of ENERGY STAR Version 3.0[1] (effective date: October 9, 2025) and ENERGY STAR Most Efficient 2025 criteria (effective date: January 1, 2025) is purchased and installed in place of a model meeting the current federal standard.

This measure was developed to be applicable to the following program types: TOS, NC.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as an air purifier meeting the efficiency specifications of ENERGY STAR as provided below.

- Must produce a minimum 30 Clean Air Delivery Rate (CADR) for $PM_{2.5}$[2] to be considered under this specification. Minimum Performance Requirement is expressed in $PM_{2.5}$ CADR/Watt and it shall be greater than or equal to the Minimum $PM_{2.5}$ CADR/Watt Requirement shown in the table below:

CADR Range	Integrated Energy Factor ($PM_{2.5}$ CADR/W)	
	ENERGY STAR	ENERGY STAR Most Efficient
30 ≤ $PM_{2.5}$ CADR < 100	4.4	5.4
100 ≤ $PM_{2.5}$ CADR < 150	5.4	6.6
$PM_{2.5}$ CADR ≥ 150	5.6	8.6

- "Partial On Mode" Requirements are to be calculated as per Section 3.4.1 of the Energy Star Eligibility Criteria [3]
- UL Safety Requirement: Models that emit ozone as a byproduct of air cleaning must meet UL Standard 867 (ozone production must not exceed 50ppb)

DEFINITION OF BASELINE EQUIPMENT

The baseline for this measure is defined as a new air purifier that meets the Code of Federal Regulations appliance federal efficiency standards. As of December 31, 2025, those are as defined below for air cleaners[4]:

CADR Range	Integrated Energy Factor ($PM_{2.5}$ CADR/W)
	Tier 2 December 31, 2025
10 ≤ $PM_{2.5}$ CADR < 100	1.90
100 ≤ $PM_{2.5}$ CADR < 150	2.40

[1] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM. If then efficient equipment is certified under ENERGY STAR version 2 criteria, please refer to the Illinois TRM v13 edition of this measure.
[2] Measured according to the latest ANSI/AHAM AC-1 (AC-1) Standard
[3] ENERGY STAR® Product Specification for Room Air Cleaners - Eligibility Criteria Version 3.0, effective October 9, 2025.
[4] DOE Energy Conservation Standards for Air Cleaners, EERE–2021–BT–STD–0035, Federal Register, vol. 88, no.168, August 31, 2023. Effective date of conservation standard: December 31, 2025.

CADR Range	Integrated Energy Factor ($PM_{2.5}$ CADR/W)
	Tier 2 December 31, 2025
$PM_{2.5}$ CADR ≥ 150	2.90

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 9 years.[5]

DEEMED MEASURE COST

The incremental cost for this measure is dependent on the Air Purifier size in CADR of $PM_{2.5}$. [6]

Product Size	Minimum CADR/W	Average ENERGY STAR Purchase Cost ($)	Average Incremental Cost ($)	
			Non-IQ	IQ[7]
30 ≤ $PM_{2.5}$ CADR < 100	4.4	$117	$0	$19.50
100 ≤ $PM_{2.5}$ CADR < 150	5.4	$193	$76	$95.50
$PM_{2.5}$ CADR ≥ 150	5.6	$398	$55	$112.17

LOADSHAPE

Loadshape C53 – Flat

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = kWh_base - kWh_eff$$

$$kWh_base = (Hours * (\frac{PM_{2.5}CADR_{base}}{IEF_{base} * 1{,}000})) * IQAdj$$

$$kWh_eff = Hours * (\frac{PM_{2.5}CADR_{eff}}{IEF_{eff} * 1{,}000})$$

Where:

kWh_base = Annual Electrical Usage for baseline unit (kWh)

kWh_eff = Annual Electrical Usage for efficient unit (kWh)

Hours = Annual active operating hours

= 5840[8]

$PM_{2.5}$CADR_base = $PM_{2.5}$ CADR for baseline units, as provided in table below

IEF_base = Integrated Energy Factor; $PM_{2.5}$ CADR delivery rate per watt for baseline

[5] ENERGY STAR Qualified Room Air Cleaner Calculator citing Appliance Magazine, Portrait of the U.S. Appliance Industry 1998.
[6] ENERGY STAR V3 Room Air Cleaners Data and Analysis. See file "ENERGY STAR Version 3.0 Room Air Cleaners Data and Analysis_VEIC"
[7] IQ Incremental costs factor in the assumption that a secondhand unit costs on average 50% of a new baseline unit, and that 1/3 of IQ participants would have purchased a unit on the secondhand market. See "IQ Appliance Calculations.xls" for information.
Consistent with DOE Test Procedures 10 CFR 430.32 calculation of IEF metric.

	units, as provided in table below
1000	= Conversion factor from watts to kilowatts
IQAdj	= Baseline consumption adjustment for IQ program participants to account for a portion of participants who would have utilized the secondary market.[9]
	= 1.48 if IQ, 1.0 if non-IQ
$PM_{2.5}$CADR_eff	= $PM_{2.5}$ CADR for efficient unit
	= Actual, if unknown use values provided in table below
IEF_eff	= Integrated Energy Factor; $PM_{2.5}$ CADR delivery rate per watt for efficient units
	= Actual, if unknown use values provided in table below

Parameter assumptions for units by CADR Range:[10]

CADR Range	$PM_{2.5}$ CADR	IEF
Baseline		
30 ≤ $PM_{2.5}$ CADR < 100	58.8	1.9
100 ≤ $PM_{2.5}$ CADR < 150	121.5	2.4
$PM_{2.5}$ CADR ≥ 150	305.9	2.9
Efficient		
30 ≤ $PM_{2.5}$ CADR < 100	58.8	5.5
100 ≤ $PM_{2.5}$ CADR < 150	121.5	6.8
$PM_{2.5}$ CADR ≥ 150	305.9	7.6

	Energy Savings ΔkWh	
CADR Range	Non-IQ	IQ
30 ≤ $PM_{2.5}$ CADR < 100	118	205
100 ≤ $PM_{2.5}$ CADR < 150	191	333
$PM_{2.5}$ CADR ≥ 150	381	677

[9] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (6 years). The baseline consumption from the TRM in 2018 was increased by an estimate of 0.4% * 6 years (based on review of the refrigerator/freezer regression algorithm used in the 5.1.8 Refrigerator and Freezer Recycling measure) to account for degradation of performance over time. This secondhand consumption was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.

[10] Baseline values are consistent with ENERGY STAR v.3.0 Room Air Cleaners Data and Analysis. See file: ENERGY STAR Version 3.0 Room Air Cleaners Data and Analysis_VEIC.xlsx. Efficient values are averages within each CADR range for all models on the ENERGY STAR Qualified products list (QPL accessed: May 20, 2025). Both Baseline & Efficient Capacities (CADR) are also sourced from the ENERGY STAR QPL. For Final Savings Calcs for this measure please see: IL TRM_AirPurifier_Summary Savings Calculations_05202025.xlsx.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh}{Hours} \times CF$$

Where:

ΔkWh = Gross customer annual kWh savings for the measure

Hours = Average hours of use per year

= 5840 hours[11]

CF = Summer Peak Coincidence Factor for measure

= 66.7%[12]

	ΔkW	
CADR Range	Non-IQ	IQ
30 ≤ $PM_{2.5}$ CADR < 100	0.013	0.023
100 ≤ $PM_{2.5}$ CADR < 150	0.022	0.038
$PM_{2.5}$ CADR ≥ 150	0.044	0.077

FOSSIL FUEL SAVINGS

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

There are no operation and maintenance cost adjustments for this measure.[13]

MEASURE CODE: RS-APL-ESAP-V08-260101

REVIEW DEADLINE: 1/1/2029

[11] Consistent with DOE Test Procedures 10 CFR 430.32 calculation of IEF metric.

[12] Assumes that the purifier usage is evenly spread throughout the year, therefore coincident peak is calculated as 5840/8760 = 66.7%.

[13] Some types of room air cleaners require filter replacement or periodic cleaning, but this is likely to be true for both efficient and baseline units and so no difference in cost is assumed.

5.1.2 ENERGY STAR Clothes Washers

DESCRIPTION

This measure relates to the installation of a clothes washer meeting the ENERGY STAR[14], ENERGY STAR Most Efficient/CEE Tier 2 or CEE Advanced Tier minimum qualifications. Note if the DHW and dryer fuels of the installations are unknown (for example through a retail program) savings should be based on a weighted blend using RECS data (the resultant values (kWh, therms and gallons of water) are provided). The algorithms can also be used to calculate site specific savings where DHW and dryer fuels are known.

This measure was developed to be applicable to the following program types: TOS, NC.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Clothes washer must meet the ENERGY STAR, ENERGY STAR Most Efficient/CEE Tier 2 or CEE Advanced Tier minimum qualifications, as required by the program.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a standard sized clothes washer meeting the minimum federal baseline as of January 2018.[15]

Efficiency Level	Top Loading >2.5 Cu ft	Front Loading >2.5 Cu ft
Federal Standard	≥1.57 IMEF, ≤6.5 IWF	≥1.84 IMEF, ≤4.7 IWF
ENERGY STAR	≥2.06 IMEF, ≤4.3 IWF	≥2.76 IMEF, ≤3.2 IWF
ENERGY STAR Most Efficient/CEE Tier 2	≥2.92 IMEF, ≤3.2 IWF	
CEE Advanced Tier	≥3.1 IMEF, ≤3.0 IWF	

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 14 years[16]

DEEMED MEASURE COST

The incremental cost for an efficient unit for a non-IQ participant is assumed to be: $87, for an ENERGY STAR Most Efficient/CEE Tier 2 unit it is $85 and for a CEE Advanced Tier it is $99.[17]

For an IQ participant the incremental cost is assumed to be: $214, for an ENERGY STAR Most Efficient/CEE Tier 2 unit it is $212 and for a CEE Advanced Tier it is $227.[18]

[14] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[15] DOE Energy Conservation Standards for Clothes Washers, Appliance and Equipment Standard, 10 CFR Part 430.32(g)

[16] Based on DOE Life-Cycle Cost and Payback Period Excel-based analytical tool.

[17] Cost estimates are based on analysis of cost data provided in the 2017 Department of Energy Technical Support Document (see IL_TRM_CW Analysis_082022.xlsx). This analysis looked at incremental cost and market data from the CEC Appliance Database and attempts to find the costs associated only with the efficiency improvements. Note that the incremental cost assumes a mix of top and front loading machines available in each efficiency tier. Since CEE T2 and Advanced Tier units are all front loading, and the incremental cost is lower for these machines, the T2 incremental cost is lower than ENERGY STAR which is based on a mix of front and top- loading machines..

[18] IQ Incremental costs factor in the assumption that a secondhand unit costs on average 50% of a new baseline unit, and that 1/3 of IQ participants would have purchased a unit on the secondhand market. See "IQ Appliance Calculations.xls" for information.

DEEMED O&M COST ADJUSTMENTS

N/A

LOADSHAPE

Loadshape R01 - Residential Clothes Washer

COINCIDENCE FACTOR

The coincidence factor for this measure is 3.8%.[19]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

1. Calculate clothes washer savings based on the Integrated Modified Energy Factor (IMEF).

   The Integrated Modified Energy Factor (IMEF) includes unit operation, standby, water heating, and drying energy use: *"IMEF is the quotient of the capacity of the clothes container, C, divided by the total clothes washer energy consumption per cycle, with such energy consumption expressed as the sum of the machine electrical energy consumption, M, the hot water energy consumption, E, the energy required for removal of the remaining moisture in the wash load, D, and the combined low-power mode energy consumption"* .[20]

   The hot water and dryer savings calculated here assumes electric DHW and Dryer (this will be separated in Step 2).

IMEFsavings[21] = Capacity * (IQAdj/IMEFbase - 1/IMEFeff) * Ncycles

Where

Capacity = Clothes Washer capacity (cubic feet)

= Actual. If capacity is unknown assume 3.55 cubic feet [22]

IQAdj = Baseline consumption adjustment for IQ program participants to account for a portion of participants who would have utilized the secondary market.[23]

= 1.02 if IQ, 1.0 if non-IQ

IMEFbase = Integrated Modified Energy Factor of baseline unit

= 1.71[24]

[19] Calculated from Itron eShapes, 8760 hourly data by end use for Missouri, as provided by Ameren.
[20] Definition provided on the ENERGY STAR website.
[21] IMEFsavings represents total kWh only when water heating and drying are 100% electric.
[22] Based on the average clothes washer volume of all units that pass the new Federal Standard on the California Energy Commission (CEC) database of Clothes Washer products accessed on 04/21/2022. If utilities have specific evaluation results providing a more appropriate assumption for homes in a particular market or geographical area then that should be used.
[23] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (9 years). The baseline consumption of a unit meeting the pre 03/2015 Federal Standard was increased by an estimate of 0.4% * 9 years (based on review of the refrigerator/freezer regression algorithm used in the 5.1.8 Refrigerator and Freezer Recycling measure) to account for degradation of performance over time. For 2025 on, the post 03/2015 Federal Standard is utilized. This second hand consumption was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.
[24] Weighted average IMEF of Federal Standard rating for Front Loading and Top Loading units. Weighting is based upon the

IMEFeff = Integrated Modified Energy Factor of efficient unit

= Actual. If unknown assume average values provided below.

Ncycles = Number of Cycles per year

= 276[25]

IMEFsavings is provided below based on deemed values:[26]

Efficiency Level	IMEF	IMEF Savings (kWh)
Federal Standard	1.75	0.0
ENERGY STAR	2.21	130.6
ENERGY STAR Most Efficient/CEE Tier 2	2.92	238.4
CEE Advanced Tier	3.10	257.9

2. Break out savings calculated in Step 1 for electric DHW and electric dryer

ΔkWh = [Capacity * IQAdj/IMEFbase * Ncycles * (%CWbase + (%DHWbase * %Electric_DHW) + (%Dryerbase * %Electric_Dryer))] - [Capacity * 1/IMEFeff * Ncycles * (%CWeff + (%DHWeff * %Electric_DHW) + (%Dryereff * %Electric_Dryer))]

Where:

%CW = Percentage of total energy consumption for Clothes Washer operation (different for baseline and efficient unit – see table below)

%DHW = Percentage of total energy consumption used for water heating (different for baseline and efficient unit – see table below)

%Dryer = Percentage of total energy consumption for dryer operation (different for baseline and efficient unit – see table below)

	Percentage of Total Energy Consumption[27]		
	%CW	%DHW	%Dryer
Baseline	6.7%	15.8%	77.5%
ENERGY STAR	6.6%	13.0%	80.4%
ENERGY STAR Most Efficient/CEE Tier 2	8.2%	8.8%	82.9%
CEE Advanced Tier	8.9%	7.0%	84.1%

relative top v front loading percentage of available non-ENERGY STAR product in the CEC database (products accessed on 04/21/2022).

[25] Loads per week was estimated by taking the weighted average of the number of loads per week (midpoint used where loads per week is a range and the weights are the share of respondents falling into each number of loads per week response bin). This estimate was scaled to an IL-specific value by applying a ratio developed using the 2009 state specific values for the states in the East North Central portion of the Midwest Region. This value was then scaled to remain consistent with the volume of laundry completed on average each week between the 2009 RECS data and the new source.

[26] IMEF values are the weighted average of the new ENERGY STAR specifications. Weighting is based upon the relative top v front loading percentage of available ENERGY STAR and CEE Tier 2 products in the CEC database. See "IL TRM_CW Analysis_082024.xlsx" for the calculation.

[27] The percentage of total energy consumption that is used for the machine, heating the hot water or by the dryer is different depending on the efficiency of the unit. Values are based on a weighted average of top-loading and front-loading units based on data from the 2017 DOE Life-Cycle Cost and Payback Period Excel-based analytical tool. See "IL TRM_CW Analysis_082024.xlsx" for the calculation.

%Electric_DHW = Percentage of DHW savings assumed to be electric

= 100 % for Electric

= 0 % for Fossil Fuel

= If unknown[28], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	19.7%	30.6%	63.3%	67.3%	31.4%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
People's Gas	2.1%	2.0%	1.7%	2.4%	2.2%
Northshore Gas	1.5%	1.8%	10.0%	2.4%	2.4%
Nicor Gas	7.6%	9.9%	14.4%	22.6%	10.0%
All DUs[29]					**29%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

%Electric_Dryer = Percentage of dryer savings assumed to be electric[30]

	%Electric_Dryer (By Utility)					
Dryer fuel	**Ameren**	**ComEd**	**PG**	**NS**	**Nicor**	**Unknown**
Electric	100%					
Natural Gas	0%					
Unknown	76%	42%	49%	30%	32%	45%

Using the default/unknown assumptions provided above, the prescriptive savings for each configuration are presented below (using unknown utility %Electric_DHW and %Electric_Dryer values):

	ΔkWH – Non IQ Participants								
	Electric DHW Electric Dryer	**Gas DHW Electric Dryer**	**Electric DHW Gas Dryer**	**Gas DHW Gas Dryer**	**Electric DHW Unknown Dryer**	**Gas DHW Unknown Dryer**	**Unknown DHW Electric Dryer**	**Unknown DHW Gas Dryer**	**Unknown DHW Unknown Dryer**
ENERGY STAR	130.6	97.6	42.4	9.4	82.1	49.1	107.2	19.0	58.7
ENERGY STAR Most	238.4	177.2	72.1	11.0	146.9	85.8	195.0	28.7	103.5

[28] All values except for Peoples Gas and Northshore Gas are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. Peoples Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[29] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[30] Based on data from GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. Market type assumptions were extracted for each utility and then utility specific market share weightings applied to provide a single utility value. See "Res Baseline Study Workbook.xls" for more detail.

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) / 1{,}000{,}000 * E_{water\ total}$$

Where

ΔWater (gallons) = Water saved, in gallons – as calculated below.

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

=5,010[31]

Using defaults provided:

ENERGY STAR ΔkWh_{water} = 1,595/1,000,000 * 5,010

= 8.0 kWh [8.5 kWh for IQ]

ENERGY STAR Most Efficient/CEE Tier 2 ΔkWh_{water} = 2,500/1,000,000 * 5,010

= 12.5 kWh [13.1 kWh for IQ]

CEE Advanced Tier ΔkWh_{water} = 2,709/1,000,000 * 5,010

= 13.6 kWh [14.2 kWh for IQ]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh/Hours * CF

Where:

[31] This factor includes 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

ΔkWh = Energy Savings as calculated above. Note do not include the secondary savings in this calculation.

Hours = Assumed Run hours of Clothes Washer

= 276 hours[32]

CF = Summer Peak Coincidence Factor for measure.

= 0.038[33]

Using the default assumptions provided above, the prescriptive savings for each configuration are presented below (using unknown utility %Electric_DHW and %Electric_Dryer values):

	ΔkW- Non IQ Participants								
	Electric DHW Electric Dryer	Gas DHW Electric Dryer	Electric DHW Gas Dryer	Gas DHW Gas Dryer	Electric DHW Unknown Dryer	Gas DHW Unknown Dryer	Unknown DHW Electric Dryer	Unknown DHW Gas Dryer	Unknown DHW Unknown Dryer

FOSSIL FUEL SAVINGS

Break out savings calculated in Step 1 of electric energy savings (MEF savings) and extract Natural Gas DHW and Natural Gas dryer savings from total savings:

ΔTherm = [(Capacity * IQAdj/IMEFbase * Ncycles * ((%DHWbase * %Fossil_DHW * R_eff) + (%Dryerbase * %Gas _Dryer))) – (Capacity * 1/IMEFeff * Ncycles * ((%DHWeff * %Fossil_DHW * R_eff) + (%Dryereff * %Gas_Dryer)))] * Therm_convert

Where:

Therm_convert = Convertion factor from kWh to Therm

= 0.03412

[32] Based on a weighted average of 276 clothes washer cycles per year assuming an average load runs for one hour (Loads per week was estimated by taking the weighted average of the number of loads per week (midpoint used where loads per week is a range and the weights are the share of respondents falling into each number of loads per week response bin). This estimate was scaled to an IL-specific value by applying a ratio developed using the 2009 state specific values for the states in the East North Central portion of the Midwest Region. This value was then scaled to remain consistent with the volume of laundry completed on average each week between the 2009 RECS data and the new source.)

[33] Calculated from Itron eShapes, 8760 hourly data by end use for Missouri, as provided by Ameren.

R_eff = Recovery efficiency factor

= 1.26[34]

%Fossil_DHW = Percentage of DHW savings assumed to be Fossil Fuel

= 100 % for Fossil fuel

= 0 % for Electric

= If unknown[35], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs[36]					**71%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

%Fossil_Dryer = Percentage of dryer savings assumed to be fossil fuel[37]

Dryer fuel	**%Fossil_Dryer (By Utility)**					
	Ameren	**ComEd**	**PG**	**NS**	**Nicor**	**Unknown**
Electric	0%					
Natural Gas	100%					
Unknown	24%	58%	51%	70%	68%	55%

Other factors as defined above.

Using the default/unknown assumptions provided above, the prescriptive savings for each configuration are presented below (using unknown utility %Fossil_DHW and %Fossil_Dryer values):

[34] To account for the different efficiency of electric and Natural Gas hot water heaters (gas water heater: recovery efficiencies ranging from 0.74 to 0.85 (0.78 used), and electric water heater with 0.98 recovery efficiency (see ENERGY STAR Waste Water Recovery Guidelines). Therefore, a factor of 0.98/0.78 (1.26) is applied.

[35] All values except for Peoples Gas and Northshore Gas are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. Peoples Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[36] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[37] Based on data from GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. Market type assumptions were extracted for each utility and then utility specific market share weightings applied to provide a single utility value. See "Res Baseline Study Workbook.xls" for more detail.

WATER IMPACT DESCRIPTIONS AND CALCULATION

$$\Delta Water\ (gallons) = Capacity * ((IWFbase * IQAdj_{Water}) - IWFeff) * Ncycles$$

Where

ΔWater (gallons) = Water saved, in gallons

IWFbase = Integrated Water Factor of baseline clothes washer

= 5.59[38]

$IQAdj_{Water}$ = Baseline water consumption adjustment for IQ program participants to account for a portion of participants who would have utilized the secondary market.[39]

= 1.02, 1.0 if non-IQ

IWFeff = Water Factor of efficient clothes washer

= Actual. If unknown assume average values provided below.

Using the default assumptions provided above, the prescriptive water savings for each efficiency level are presented below:

Efficiency Level	IWF	ΔWater (gallons per year)	
		Non-IQ	IQ
Federal Standard	5.59	N/A	N/A

[38] Weighted average IWF of Federal Standard rating for Front Loading and Top Loading units. Weighting is based upon the relative top v front loading percentage of available non-ENERGY STAR product in the CEC database (products accessed on 04/21/2022).

[39] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (9 years). The baseline consumption from the TRM in 2015 is assumed the second hand water consumption (note we do no assume a degradation over time for water consumption) was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.

Efficiency Level	IWF	ΔWater (gallons per year)	
		Non-IQ	IQ
ENERGY STAR	4.07	1,492	1,596
ENERGY STAR Most Efficient/CEE Tier 2	3.2	2,339	2,448
CEE Advanced Tier	3	2,535	2,644

MEASURE CODE: RS-APL-ESCL-V14-260101

REVIEW DEADLINE: 1/1/2029

5.1.3 ENERGY STAR Dehumidifier

DESCRIPTION

A dehumidifier meeting the minimum qualifying efficiency standard established by the current ENERGY STAR[40] Version 6.0 (effective 10/01/2025) and ENERGY STAR Most Efficient 2025 Criteria (effective 01/01/2025) is purchased and installed in a residential setting in place of a unit that meets the minimum federal standard efficiency.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the new dehumidifier must meet the ENERGY STAR standards as defined below:

Equipment Specification	Product Capacity	ENERGY STAR Criteria	ENERGY STAR Most Efficient Criteria
	(Pints/Day)	(L/kWh)	(L/kWh)
Portable Dehumidifier	≤ 25	≥1.70	≥1.85
	>25 and ≤ 50	≥2.01	≥2.20
	>50 and < 155	≥3.30	≥3.40
Whole Home Dehumidifier	**Product Case Volume**	**ENERGY STAR Criteria**	**ENERGY STAR Most Efficient Criteria**
	≤ 8.0	≥ 2.22	≥2.35
	> 8.0	≥ 3.81	≥3.81

Qualifying units shall be equipped with an adjustable humidistat control or shall require a remote humidistat control to operate.

DEFINITION OF BASELINE EQUIPMENT

The baseline for this measure is defined as a new dehumidifier that meets the Code of Federal Regulations appliance federal efficiency standards. As of June 13, 2019, those are as defined below for Dehumidifiers:

Equipment Specification	Capacity (pints/day)	Federal Standard Criteria (L/kWh)
Portable Dehumidifier	≤25	≥1.30
	>25 and ≤ 50	≥1.60
	>50 and <155	≥2.80
Whole Home Dehumidifier	**Product Case Volume**	**Federal Standard Criteria (L/kWh)**
	≤ 8.0	≥ 1.77
	> 8.0	≥ 2.41

[40] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime for Portable Dehumidifiers is 12 years[41] and for Whole Home Humidifiers it is 17 years.[42]

DEEMED MEASURE COST

The incremental cost is the difference in cost between a baseline and an ENERGY STAR qualified unit. Please see the table below for cost assumptions used:

Equipment Specification	Population	ENERGY STAR	ENERGY STAR Most Efficient
Portable Dehumidifier	Non-IQ[43]	$9	$12
	IQ[44]	$55	$59
Whole Home Humidifier	Non-IQ[2]	$143[45]	$174
	IQ	N/A	N/A

LOADSHAPE

Loadshape R12 - Residential - Dehumidifier

COINCIDENCE FACTOR

The coincidence factor is assumed to be 50%.[46]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (((Capacity * 0.473) / 24) * Hours) * (IQAdj / (L/kWh_Base) - 1 / (L/kWh_Eff))$$

Where:

Capacity = Water removal capacity of the unit (pints/day)

= Actual, if unknown assume capacity in each capacity range as provided in table below,

[41] EPA Research, 2012; ENERGY STAR Appliance Calculator,

[42] TECHNICAL SUPPORT DOCUMENT: ENERGY EFFICIENCY PROGRAM FOR CONSUMER PRODUCTS AND COMMERCIAL AND INDUSTRIAL EQUIPMENT: DEHUMIDIFIERS, October 2023. https://www.regulations.gov/document/EERE-2019-BT-STD-0043-0023, Appendix 8C. Lifetime is assumed to be the age at which there is an 80% cumulative probability that the unit has failed.

[43] Incremental cost data from the TECHNICAL SUPPORT DOCUMENT: ENERGY EFFICIENCY PROGRAM FOR CONSUMER PRODUCTS AND COMMERCIAL AND INDUSTRIAL EQUIPMENT: DEHUMIDIFIERS, October 2023. https://www.regulations.gov/document/EERE-2019-BT-STD-0043-0023. See Dehumidifiers_Calculation_Sheet_05-09-24.xlsx for more detail regardinging the incremental cost data.

[44] IQ Incremental costs factor in the assumption that a secondhand unit costs on average 50% of a new baseline unit, and that 1/3 of IQ participants would have purchased a unit on the secondhand market. The new baseline dehumidifier is assumed to cost $262 based on values reported in: . See "IQ Appliance Calculations.xls" for information.

[45] ENERGY STAR Version 6.0 Dehumidifiers Draft 1 Specification Stakeholder Webinar presentation, March 28, 2024. Purchase price incremental cost between current DOE standard and Draft 1 v.6.0 for units ≤ 8.0 ft^3.

[46] Assume usage is evenly distributed day vs. night, weekend vs. weekday and is used between April through the end of September (4392 possible hours). With 2,200 operating hours, coincidence peak during summer peak is therefore 2200/4392 = 50.1%

or if capacity range unknown assume average.

0.473 = Constant to convert Pints to Liters

24 = Constant to convert Liters/day to Liters/hour

Hours = Run hours per year

= 2,200[47]

IQAdj = Baseline consumption adjustment for IQ program participants to account for a portion of participants who would have utilized the secondary market. [48]

= 1.096 for Portable Dehumidifiers if IQ, 1.0 if non-IQ or Whole Home Dehumidifiers

L/kWh = Liters of water per kWh consumed, as provided in tables above

Annual kWh usage and savings, for each capacity class and product type, are presented in the four tables below:

Portable Dehumidifiers					Annual kWh			
Capacity Range	Capacity Used[49]	Federal Standard Criteria	ENERGY STAR Criteria	ENERGY STAR Most Efficient Criteria	Non-IQ Baseline: Federal Standard	IQ Baseline	ENERGY STAR	ENERGY STAR Most Efficient
(pints/day)	(pints/day)	(≥ L/kWh)	(≥ L/kWh)	(≥ L/kWh)				
≤25	20	1.3	1.7	1.85	667	731	510	469
>25 and ≤50	37.5	1.6	2.01	2.2	1016	1114	809	739
>50 and <155	102.5	2.8	3.3	3.4	1587	1740	1347	1307
Average[50]	38.2	1.54	1.95	2.13	778	1178	630	778
Whole Home Dehumidifiers[51]					**Annual kWh**			
Product Case Volume (sqft.)	Capacity Used[52]	Federal Standard Criteria	ENERGY STAR Criteria	ENERGY STAR Most Efficient Criteria	Non-IQ Baseline: Federal Standard	IQ Baseline	ENERGY STAR	ENERGY STAR Most Efficient
≤ 8.0	55	1.77	2.22	2.35	2127	N/A	1696	1602

[47] Based on Mattison et al., "Dehumidifiers: A Major Consumer of Residential Electricity", Cautley et al., "Dehumidification and Subslab Ventilation in Wisconsin Homes" and Yang et al., "Dehumidifier Use in the U.S. Residential Sector", all indicating average usage around 2,200 hours per year.

[48] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (8 years). In 2019 a new Federal Standard became effective and "relative to the previous standard, the current standard represents energy savings of about 15-25%". 20% was used and increased by an estimate of 0.4% * 8 years (based on review of the refrigerator/freezer regression algorithm used in the 5.1.8 Refrigerator and Freezer Recycling measure) to account for degradation of performance over time. This secondhand consumption was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.

[49] Capacity Used in calculations for each bin is an average. See next footnote regarding overall average for Portable Dehumidifiers

[50] Weighted Overall average based on ENERGY STAR Products List 2025 for Dehumidifiers, accessed May 2025. See sheet estar-2025-05 in file "ENERGY STAR Dehumidifier TRM Analysis_2025.xlsx"

[51] There are currently no ENERGY STAR whole-home dehumidifiers with a product case volume > 8.0 sqft. Savings for any dehumidifiers in this category will need to be calculated with actual performance values utilizing the savings algorithm above

[52] Capacity Used in calculations for each bin is an average. See next footnote regarding overall average for Portable Dehumidifiers

Portable Dehumidifier		Energy Savings (ΔkWh)			
		Non-IQ		IQ	
Capacity Range (pints/day)	Capacity Used (pints/day)	ENERGY STAR	ENERGY STAR Most Efficient	ENERGY STAR	ENERGY STAR Most Efficient
≤25	20	157	198	221	262
>25 and ≤50	37.5	207	277	305	375
>50 and <155	102.5	241	280	393	432
Average	38.2	226	297	329	400
Whole Home Dehumidifiers		**Energy Savings (ΔkWh)**

5.1.4 ENERGY STAR Dishwasher

DESCRIPTION

A standard or compact residential dishwasher meeting ENERGY STAR[54] standards is installed in place of a model meeting the federal standard.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as a standard or compact dishwasher meeting the ENERGY STAR standards presented in the table below.

ENERGY STAR Requirements (Version 7.0, Effective July 19, 2023)

Dishwasher Type	Maximum kWh/year	Maximum gallons/cycle
Standard (≥ 8 place settings + six serving pieces)	240	3.2
Standard with Connected Functionality[55]	252	
Compact (< 8 place settings + six serving pieces)	155	2.0

DEFINITION OF BASELINE EQUIPMENT

The baseline reflects the minimum federal efficiency standards for dishwashers effective May 30, 2013, as presented in the table below.

Dishwasher Type	Maximum kWh/year	Maximum gallons/cycle
Standard	307	5.0
Compact	222	3.5

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of the measure is 11 years.[56]

DEEMED MEASURE COST

The incremental cost for standard and compact dishwashers is provided in the table below:[57]

[54] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[55] The ENERGY STAR specification "establishes optional connected criteria for dishwashers. ENERGY STAR certified dishwashers with connected functionality offer favorable attributes for demand response programs to consider, since their peak energy consumption is relatively high, driven by water heating. ENERGY STAR certified dishwashers with connected functionality will offer consumers new convenience and energy-saving features, such as alerts for cycle completion and/or recommended maintenance, as well as feedback on the energy use of the product". See 'ENERGY STAR Residential Dishwasher Final Version 6.0 Cover Memo.pdf'. Calculated as per Version 6.0 specification; "ENERGY STAR Residential Dishwasher Version 6.0 Final Program Requirements.pdf". As of July 2021, Version 7.0 specification is still under development. Note that the potential for demand response and additional peak savings from units with Connected Functionality have not been explored. This could be a potential addition in a future version.

[56] Measure lifetime from California DEER. See file California DEER 2014-EUL Table - 2014 Update.xlsx.

[57] Costs are based on data from U.S. DOE, Final Rule Life-Cycle Cost (LCC) Spreadsheet. See file Residential Dishwasher Analysis_2021.xlsx for cost calculation details.

Dishwasher Type	Baseline Cost		ENERGY STAR Cost	Incremental Cost	
	Non-IQ	IQ[58]		Non-IQ	IQ
Standard	$310	$213.03	$340	$30	$118.28
Compact	$290.13	$241.78	$308.62	$18.49	$66.85

LOADSHAPE

Loadshape R02 - Residential Dish Washer

COINCIDENCE FACTOR

The coincidence factor is assumed to be 2.6%.[59]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh^{60} = ((kWh_{Base} - kWh_{ESTAR}) * (\%kWh_op + (\%kWh_heat * \%Electric_DHW)))$$

Where:

kWh_{BASE} = Baseline kWh consumption per year

Dishwasher Type	Maximum kWh/year	
	Non-IQ	IQ[61]
Standard	307	310
Compact	222	224

kWh_{ESTAR} = ENERGY STAR kWh annual consumption

Dishwasher Type	Maximum kWh/year
Standard	240
Standard with Connected Functionality	252
Compact	155

%kWh_op = Percentage of dishwasher energy consumption used for unit operation

= 100 - 56%[62]

[58] IQ Incremental costs factor in the assumption that a secondhand unit costs on average 50% of a new baseline unit, and that 1/3 of IQ participants would have purchased a unit on the secondhand market. See "IQ Appliance Calculations.xls" for information.

[59] Calculated from Itron eShapes, 8760 hourly data by end use for Missouri, as provided by Ameren.

[60] The Federal Standard and ENERGY STAR annual consumption values include electric consumption for both the operation of the machine and for heating the water that is used by the machine.

[61] It is assumed that a secondhand unit is on average 2/3 of a measure's EUL years old (7 years). There has been no new Federal Standard in that period, but new unit baseline consumption is increased by an estimate of 0.4% * 7 years (based on review of the refrigerator/freezer regression algorithm used in the 5.1.8 Refrigerator and Freezer Recycling measure) to account for degradation of performance over time. This secondhand consumption was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.

[62] ENERGY STAR Qualified Appliance Savings Calculator, last updated October 2016.

= 44%

%kWh_heat = Percentage of dishwasher energy consumption used for water heating

= 56%[63]

%Electric_DHW = Percentage of DHW savings assumed to be electric

= 100 % for Electric

= 0 % for Fossil Fuel

= If unknown[64], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	19.7%	30.6%	63.3%	67.3%	31.4%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
People's Gas	2.1%	2.0%	1.7%	2.4%	2.2%
Northshore Gas	1.5%	1.8%	10.0%	2.4%	2.4%
Nicor Gas	7.6%	9.9%	14.4%	22.6%	10.0%
All DUs[65]					**29%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Dishwasher Type	ΔkWh - Non IQ			ΔkWh - IQ		
	With Electric DHW	**With Gas DHW**	**With Unknown location and building type DHW**	**With Electric DHW**	**With Gas DHW**	**With Unknown location and building type DHW**
ENERGY STAR Standard	67.0	29.5	40.4	70.0	30.8	42.2
ENERGY STAR Standard with Connected Functionality	55.0	24.2	33.1	58.0	25.5	34.9
ENERGY STAR Compact	67.0	29.5	40.4	69.0	30.4	41.6

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) / 1{,}000{,}000 * E_{water\ total}$$

Where

[63] Ibid.

[64] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[65] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

=5,010[66]

Using defaults provided:

Standard ΔkWh_{water} = 252/1,000,000 * 5,010

= 1.3 kWh

Compact ΔkWh_{water} = 67/1,000,000 * 5,010

= 0.3 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS[67]

$\Delta kW = \Delta kWh/Hours * CF$

Where:

ΔkWh = Annual kWh savings from measure as calculated above. Note do not include the secondary savings in this calculation.

Hours = Annual operating hours[68]

= 353 hours

CF = Summer Peak Coincidence Factor

= 2.6% [69]

Dishwasher Type	ΔkW - Non IQ			ΔkW - IQ		
	With Electric DHW	With Gas DHW	With Unknown location and building type DHW	With Electric DHW	With Gas DHW	With Unknown location and building type DHW
ENERGY STAR Standard	0.0049	0.0022	0.0030	0.0052	0.0023	0.0031
ENERGY STAR Standard with Connected Functionality	0.0041	0.0018	0.0024	0.0043	0.0019	0.0026
ENERGY STAR Compact	0.0049	0.0022	0.0030	0.0051	0.0022	0.0031

FOSSIL FUEL SAVINGS

$\Delta\ Therm = (kWh_{Base} - kWh_{ESTAR}) * \%kWh_heat * \%Fossil_DHW * R_eff * 0.03412$

Where

%kWh_heat = % of dishwasher energy used for water heating

= 56%

[66] This factor includes 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information, please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

[67] Note that the potential for demand response and additional peak savings from units with Connected Functionality have not been explored. This could be a potential addition in a future version.

[68] Assuming 2.1 hours per cycle and 168 cycles per year therefore 353 operating hours per year. 168 cycles per year is based on a weighted average of dishwasher usage in Illinois derived from the 2009 RECs data.

[69] End use data from Ameren representing the average DW load during peak hours/peak load.

%Fossil_DHW = Percentage of DHW savings assumed to be fossil fuel

= 100 % for Fossil Fuel

= 0 % for Electric

= If unknown[70], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs[71]					**71%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

R_eff = Recovery efficiency factor

= 1.26[72]

0.03412 = factor to convert from kWh to Therm

Dishwasher Type	ΔTherms - Non IQ			ΔTherms - IQ

5.1.5 ENERGY STAR Freezer

DESCRIPTION

A freezer meeting the efficiency specifications of ENERGY STAR[75] is installed in place of a model meeting the federal standard (NAECA). Energy usage specifications are defined in the table below (note, AV is the freezer Adjusted Volume and is calculated as 1.73*Total Volume):

Product Category	Volume (cubic feet)	Assumptions after September 2014	
		Federal Baseline Maximum Energy Usage in kWh/year[76]	ENERGY STAR Maximum Energy Usage in kWh/year[77]
Upright Freezers with Manual Defrost	7.75 or greater	5.57*AV + 193.7	5.01*AV + 174.3
Upright Freezers with Automatic Defrost	7.75 or greater	8.62*AV + 228.3	7.76*AV + 205.5
Chest Freezers and all other Freezers except Compact Freezers	7.75 or greater	7.29*AV + 107.8	6.56*AV + 97.0
Compact Upright Freezers with Manual Defrost	< 7.75 and 36 inches or less in height	8.65*AV + 225.7	7.79*AV + 203.1
Compact Upright Freezers with Automatic Defrost	< 7.75 and 36 inches or less in height	10.17*AV + 351.9	9.15*AV + 316.7
Compact Chest Freezers	<7.75 and 36 inches or less in height	9.25*AV + 136.8	8.33*AV + 123.1

This measure was developed to be applicable to the following program types: TOS, NC.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as a freezer meeting the efficiency specifications of ENERGY STAR, as defined below and calculated above:

Equipment	Volume	Criteria
Full Size Freezer	7.75 cubic feet or greater	At least 10% more energy efficient than the minimum federal government standard (NAECA).
Compact Freezer	Less than 7.75 cubic feet and 36 inches or less in height	At least 20% more energy efficient than the minimum federal government standard (NAECA).

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be a model that meets the federal minimum standard for energy efficiency. The standard varies depending on the size and configuration of the freezer (chest freezer or upright freezer, automatic or manual defrost) and is defined in the table above.

[75] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[76] See Department of Energy Federal Standards, (10 CFR Part 430.32(a)), effective September 15th, 2014.
[77] See Version 5.1 ENERGY STAR specification.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 21 years for standard size and 10 years for compact freezers.[78]

DEEMED MEASURE COST

The incremental cost for this measure is $5[79] for non-IQ participants and $104 for IQ participants.[80]

LOADSHAPE

Loadshape R04 - Residential Freezer

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 95%.[81]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS:

$$\Delta kWh = (kWh_{Base} * IQAdj) - kWh_{ESTAR}$$

Where:

kWh_{BASE} = Baseline kWh consumption per year as calculated in algorithm provided in table above.

IQAdj = Baseline consumption adjustment for IQ program participants to account for a portion of participants who would have utilized the secondary market. [82]

= 1.14 if IQ, 1.0 if non-IQ

kWh_{ESTAR} = ENERGY STAR kWh consumption per year as calculated in algorithm provided in table above.

[78] Based on 2021 DOE Rulemaking Technical Support Document, "Refrigerator, Refrigerator-Freezer, and Freezer Life-Cycle Cost (LCC) Analysis Spreadsheet" posted November 9, 2021.

[79] Costs are estimated using the data provided in the Department of Energy, "Refrigerator, Refrigerator-Freezer, and Freezer Life-Cycle Cost (LCC) Analysis Spreadsheet" posted November 9, 2021 as part of the 'Energy Conservation Standards for Consumer Refrigerators, Refrigerator-Freezers, and Freezers' rulemaking docket. Install cost data was trended to provide estimates at the efficiency levels specified in this measure, and then weighted based on available product on the ENERGY STAR Freezer QPI, accessed 4/29/2022. See "DOE LCC Spreadsheet_Freezer.xls" for more information.

[80] IQ Incremental costs factor in the assumption that a secondhand unit costs on average 50% of a new baseline unit, and that 1/3 of IQ participants would have purchased a unit on the secondhand market. See "IQ Appliance Calculations.xls" for information.

[81] Based on eShapes Residential Freezer load data as provided by Ameren.

[82] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (14 years). The current Federal Standard became effective in 2014 so the previous standard is used to estimate base consumption for a second hand unit, and further increased by an estimate of 0.4% * 14 years (based on review of the refrigerator/freezer regression algorithm used in the 5.1.8 Refrigerator and Freezer Recycling measure) to account for degradation of performance over time. This second hand consumption was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.

For example for a 7.75 cubic foot Upright Freezers with Manual Defrost purchased by non-IQ participant after September 2014:

ΔkWh = ((5.57*(7.75* 1.73)+193.7)) * 1) – (5.01*(7.75* 1.73)+174.3)
= 268.4 – 241.5
= 26.9 kWh

If volume is unknown, use the following default values:

Product Category	Adjusted Volume Used[83]	kWh_{BASE}		kWh_{ESTAR}	ΔkWh	
		Non-IQ	IQ		Non-IQ	IQ
Upright Freezers with Manual Defrost	15	277.3	316	249.5	27.8	66.2
Upright Freezers with Automatic Defrost	26.2	453.9	517	408.6	45.3	108.1
Chest Freezers and all other Freezers except Compact Freezers	22.5	271.9	310	244.7	27.2	64.8
Compact Upright Freezers with Manual Defrost	5.5	273.3	311	246	27.3	65.1
Compact Upright Freezers with Automatic Defrost	7.5	428.6	488	385.7	42.9	102.2
Compact Chest Freezers	9.5	224.8	256	202.4	22.5	53.5

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh/ Hours * CF

Where:

ΔkWh = Gross customer annual kWh savings for the measure

Hours = Full Load hours per year
= 5890[84]

CF = Summer Peak Coincident Factor
= 0.95 [85]

For example, for a 7.75 cubic foot Upright Freezers with Manual Defrost purchased by non-IQ participant:

ΔkW = 26.9/5890 * 0.95
= 0.0043 kW

If volume is unknown, use the following default values:

Product Category	ΔkW	
	Non-IQ	IQ
Upright Freezers with Manual Defrost	0.0045	0.0107

[83] Volume is based on average adjusted volume of units on the ENERGY STAR QPI, accessed 4/29/2022. See "DOE LCC Spreadsheet_Freezer.xls" for more information.
[84] Calculated from eShapes Residential Freezer load data as provided by Ameren by dividing total annual load by the maximum kW in any one hour.
[85] Based on eShapes Residential Freezer load data as provided by Ameren.

Product Category	ΔkW	
	Non-IQ	IQ
Upright Freezers with Automatic Defrost	0.0073	0.0174
Chest Freezers and all other Freezers except Compact Freezers	0.0044	0.0105
Compact Upright Freezers with Manual Defrost	0.0044	0.0105
Compact Upright Freezers with Automatic Defrost	0.0069	0.0165
Compact Chest Freezers	0.0036	0.0086

MEASURE CODE: RS-APL-ESFR-V06-260101

REVIEW DEADLINE: 1/1/2027

5.1.6 ENERGY STAR, CEE Tier 2 or CEE Tier 3 Refrigerator

DESCRIPTION

This measure relates to:

a) Time of Sale: the purchase and installation of a new refrigerator meeting either ENERGY STAR[86], CEE TIER 2 or TIER 3 specifications.

b) Early Replacement: the early removal of an existing residential inefficient Refrigerator from service, prior to its natural end of life, and replacement with a new ENERGY STAR, CEE Tier 2 or Tier 3 qualifying unit. Savings are calculated between existing unit and efficient unit consumption during the remaining life of the existing unit, and between new baseline unit and efficient unit consumption for the remainder of the measure life.

Energy usage specifications are defined in the table below (note, Adjusted Volume is calculated as the fresh volume + (1.63 * Freezer Volume):

Product Category	Existing Unit	Assumptions after September 2014	
	Based on Refrigerator Recycling algorithm	Federal Baseline Maximum Energy Usage in kWh/year[87]	ENERGY STAR Maximum Energy Usage in kWh/year[88]
1. Refrigerators and Refrigerator-freezers with manual defrost	Use Algorithm in 5.1.8 Refrigerator and Freezer Recycling measure to estimate existing unit consumption	6.79AV + 193.6	6.11 * AV + 174.2
2. Refrigerator-Freezer--partial automatic defrost		7.99AV + 225.0	7.19 * AV + 202.5
3. Refrigerator-Freezers--automatic defrost with top-mounted freezer without through-the-door ice service and all-refrigerators--automatic defrost		8.07AV + 233.7	7.26 * AV + 210.3
4. Refrigerator-Freezers--automatic defrost with side-mounted freezer without through-the-door ice service		8.51AV + 297.8	7.66 * AV + 268.0
5. Refrigerator-Freezers--automatic defrost with bottom-mounted freezer without through-the-door ice service		8.85AV + 317.0	7.97 * AV + 285.3
5A Refrigerator-freezer—automatic defrost with bottom-mounted freezer with through-the-door ice service		9.25AV + 475.4	8.33 * AV + 436.3
6. Refrigerator-Freezers--automatic defrost with top-mounted freezer with through-the-door ice service		8.40AV + 385.4	7.56 * AV + 355.3
7. Refrigerator-Freezers--automatic defrost with side-mounted freezer with through-the-door ice service		8.54AV + 432.8	7.69 * AV + 397.9

This measure was developed to be applicable to the following program types: TOS, NC, EREP.

If applied to other program types, the measure savings should be verified.

[86] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[87] See Department of Energy Federal Standards (10 CFR Part 430.32(a)), effective September 15th, 2014.

[88] See Version 5.1 ENERGY STAR specification.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as a refrigerator meeting the efficiency specifications of ENERGY STAR, CEE Tier 2 or CEE Tier 3 (defined as requiring >= 10%, >= 15% or >=20% less energy consumption than an equivalent unit meeting federal standard requirements respectively). The ENERGY STAR standard varies according to the size and configuration of the unit, as shown in table above.

DEFINITION OF BASELINE EQUIPMENT

Time of Sale: baseline is a new refrigerator meeting the minimum federal efficiency standard for refrigerator efficiency. The current federal minimum standard varies according to the size and configuration of the unit, as shown in table above. This Federal Standard is effective for units manufactured after September 1, 2014. Note in December 2021, the DOE presented preliminary analysis for the purposes of evaluating energy conservation standards. The review deadline will be set for one further year to review progress in standard updates.

Early Replacement: the baseline is the existing refrigerator for the assumed remaining useful life of the unit and the new baseline as defined above for the remainder of the measure life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 15 years.[89]

Remaining life of existing equipment is assumed to be 5 years.[90]

DEEMED MEASURE COST

Time of Sale: The incremental cost for non-IQ participants is assumed to be $9 for an ENERGY STAR unit, $26 for a CEE Tier 2 unit and $135 for a CEE Tier 3 unit.[91]

For IQ participants the incremental cost is assumed to be $154 for an ENERGY STAR unit, $171 for a CEE Tier 2 unit and $180 for a CEE Tier 3 unit. [92]

Early Replacement: The measure cost is the full cost of removing the existing unit and installing a new one. The actual program cost should be used. If unavailable, assume $878 for ENERGY STAR unit, $895 for CEE Tier 2 unit and $904 for CEE Tier 3 units.

The avoided replacement cost (after 5 years) of a baseline replacement refrigerator is $973[93]. This cost should be discounted to present value using the nominal societal discount rate.

LOADSHAPE

Loadshape R05 - Residential Refrigerator

COINCIDENCE FACTOR

A coincidence factor is not used to calculate peak demand savings for this measure, see below.

[89] Based on 2021 DOE Rulemaking Technical Support Document, "Refrigerator, Refrigerator-Freezer, and Freezer Life-Cycle Cost (LCC) Analysis Spreadsheet" posted November 9, 2021.
[90] Standard assumption of one third of effective useful life.
[91] Costs are estimated using the data provided in the Guidehouse and Leidos Technology Forecast Updates Residential and Commercial Building Technologies Reference Case presented to U.S. Energy Information Administration March 3, 2023.
[92] IQ Incremental costs factor in the assumption that a secondhand unit costs on average 50% of a new baseline unit, and that 1/3 of IQ participants would have purchased a unit on the secondhand market. See "IQ Appliance Calculations.xls" for information.
[93] Estimated by taking the incremental cost from the ENERGY STAR cost and applying 5 years of inflation at 2.28%.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS:

Time of Sale: $\Delta kWh = (UEC_{BASE} * IQAdj) - UEC_{EE}$

Early Replacement:

ΔkWh for remaining life of existing unit (1st 5 years) $= UEC_{EXIST} - UEC_{EE}$

ΔkWh for remaining measure life (next 10 years) $= (UEC_{BASE} * IQAdj) - UEC_{EE}$

Where:

UEC_{EXIST} = Annual Unit Energy Consumption of existing unit as calculated in algorithm from 5.1.8 Refrigerator and Freezer Recycling measure.

UEC_{BASE} = Annual Unit Energy Consumption of baseline unit as calculated in algorithm provided in table above.

IQAdj = Baseline consumption adjustment for IQ program participants to account for a portion of participants who would have utilized the secondary market. [94]

= 1.04 if IQ, 1.0 if non-IQ

UEC_{EE} = Annual Unit Energy Consumption of ENERGY STAR unit as calculated in algorithm provided in table above. For CEE Tier 2, unit consumption is calculated as 15% lower than baseline and for CEE Tier 3 20% lower than baseline.

If volume is unknown, use the following defaults, based on an assumed Adjusted Volume of 22.9:[95]

Product Category	Existing Unit UEC_{EXIST}[96]	Baseline Unit UEC_{BASE}		New Efficient UEC_{EE}		
		Non-IQ	IQ	ENERGY STAR	CEE T2	CEE T3
1. Refrigerators and Refrigerator-freezers with manual defrost	998.2	349.2	363	314.2	296.8	279.4
2. Refrigerator-Freezer--partial automatic defrost	998.2	408.1	424	367.3	346.9	326.5
3. Refrigerator-Freezers--automatic defrost with top-mounted freezer without through-the-door ice service and all-refrigerators--automatic defrost	794.8	418.6	435	376.7	355.8	334.9
4. Refrigerator-Freezers--automatic defrost with side-mounted freezer without through-the-door ice service	1201.6	492.8	512	443.5	418.9	394.2
5. Refrigerator-Freezers--automatic defrost with bottom-mounted freezer without through-the-door ice service	794.8	519.8	540	467.9	441.8	415.8

[94] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (10 years). The current Federal Standard became effective in 2014 so the previous standard is used to estimate base consumption for a second hand unit, and further increased by an estimate of 0.4% * 10 years (based on review of the refrigerator/freezer regression algorithm used in the 5.1.8 Refrigerator and Freezer Recycling measure) to account for degradation of performance over time. This second hand consumption was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.

[95] Volume is based on the average adjusted volume of applicable units on the ENERGY STAR QPI, accessed 4/29/2022.

[96] Estimates of existing unit consumption are based on using the 5.1.8 Refrigerator and Freezer Recycling algorithm and the inputs described here: Age = 10 years, Pre-1990 = 0, Size = 18.9 ft3 (average of applicably units on ENERGY STAR QPI, accessed 4/29/2022), Single Door = 0, Side by side = 1 for classifications stating side by side, 0 for classifications stating top/bottom, and 0.5 for classifications that do not distinguish, Primary appliances = 1, unconditioned = 0, Part use factor = 0.

Product Category	Existing Unit UEC_{EXIST}[96]	Baseline Unit UEC_{BASE}		New Efficient UEC_{EE}		
		Non-IQ	IQ	ENERGY STAR	CEE T2	CEE T3
5A Refrigerator-freezer—automatic defrost with bottom-mounted freezer with through-the-door ice service	794.8	687.4	715	627.2	584.3	549.9

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

[97] Average temperature adjustment factor (to account for temperature conditions during peak period as compared to year as a whole) based on Blasnik, Michael, "Measurement and Verification of Residential Refrigerator Energy Use, Final Report, 2003-2004 Metering Study", July 29, 2004 (p. 47). It assumes 90 °F average outside temperature during peak period, 71°F average temperature in kitchens and 65°F average temperature in basement, and uses assumption that 66% of homes in Illinois have central cooling (CAC saturation: "Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey).

[98] Daily load shape adjustment factor (average load in peak period /average daily load) also based on Blasnik, Michael, "Measurement and Verification of Residential Refrigerator Energy Use, Final Report, 2003-2004 Metering Study", July 29, 2004 (p. 48, using the average Existing Units Summer Profile for hours 13 through 17)

REVIEW DEADLINE: 1/1/2027

5.1.7 ENERGY STAR and CEE Tier 2 Room Air Conditioner

DESCRIPTION

This measure relates to:

a) Time of Sale the purchase and installation of a room air conditioning unit that meets ENERGY STAR[99] version 5.0, which is effective October 30th 2023[100,] or CEE Tier 2 minimum qualifying efficiency specifications, in place of a baseline unit. The baseline is based on the Federal Standard effective June 1st, 2014.

Product Type and Class (Btu/hr)		Federal Standard with louvered sides (CEER) [101]	Federal Standard without louvered sides (CEER)	ENERGY STAR v5.0 with louvered sides (CEER) [102]	ENERGY STAR v5.0 without louvered sides (CEER)	CEE Tier 2 (CEER)[103]
Without Reverse Cycle	< 6,000	11.0	10.0	13.1	12.8	14.85
	6,000 - 7,999			13.7		
	8,000 to 10,999	10.9	9.6	14.7	13.0	14.72
	11,000 to 13,999	10.9	9.5	14.7	12.8	14.72
	14,000 to 19,999	10.7	9.3	14.4	12.6	14.45
	20,000 to 27,999	9.4	9.4	12.7	12.7	12.69
	>=28,000	9.0	9.4	12.2	12.7	12.15
With Reverse Cycle	<14,000	9.8	9.3	13.2	12.6	N/A
	14,000 to 19,999	9.8	8.7	13.2	11.7	N/A
	>=20,000	9.3	8.7	12.6	11.7	N/A
Casement only		9.5		12.8		
Casement-Slider		10.4		14.0		

Side louvers extend from a room air conditioner model in order to position the unit in a window. A model without louvered sides is placed in a built-in wall sleeve and are commonly referred to as "through-the-wall" or "built-in" models.

Casement-only refers to a room air conditioner designed for mounting in a casement window of a specific size.

Casement-slider refers to a room air conditioner with an encased assembly designed for mounting in a sliding or casement window of a specific size.

Reverse cycle refers to the heating function found in certain room air conditioner models. For reverse cycle units in heat pump applications, please refer to Portable HP assumptions within measure 5.3.1 Air Source Heat Pumps (Centrally Ducted, Ductless and Portable).

~~a)~~b) Early Replacement: the early removal of an existing residential inefficient Room AC unit from service, prior to its natural end of life, and replacement with a new ENERGY STAR qualifying unit. Savings are calculated between existing unit and efficient unit consumption during the remaining life of the existing unit, and between new baseline unit and efficient unit consumption for the remainder of the measure life.

[99] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[100] ENERGY STAR Version 5.0 Room Air Conditioners Program Requirements
[101] See DOE's Appliance and Equipment Standards for Room AC;
[102] ENERGY STAR Version 5.0 Room Air Conditioners Program Requirements
[103] The Consortium for Energy Efficiency Super Efficient Home Appliance Initiative, Room Air Conditioner Specification, CEE Advanced Tier (CEER), effective May 17, 2022. Please see file "CEE_RoomAC_Specification_17May2022.pdf". https://cee1.org/images/pdf/CEE_RoomAC_Specification_17May2022.pdf

Assumptions for IQ participants: This measure can be used by programs supporting the installation of efficient Room AC in income qualified households. It is assumed that the Room AC's installed in IQ households are being used less as a luxury and more as a necessity and that access to a single AC unit per household will result in run hours more consistent with central AC usage.

This measure was developed to be applicable to the following program types: TOS, NC, EREP.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the new room air conditioning unit must meet the ENERGY STAR version 5.0, which is effective October 30th 2023[104], efficiency standards presented above.

DEFINITION OF BASELINE EQUIPMENT

Time of Sale: the baseline assumption is a new room air conditioning unit that meets the Federal Standard (effective June 1st, 2014)[105] efficiency standards as presented above.

Early Replacement: the baseline is the existing Room AC for the assumed remaining useful life of the unit and the new baseline as defined above for the remainder of the measure life.

For Income Qualified units, the baseline assumption is an inefficient unit either existing in the home or being purchased or acquired via the secondary market.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 12 years.[106]

Remaining life of existing equipment is assumed to be 4 years.[107]

For Income Qualified units, because the baseline unit is assumed to be purchased from the secondary market, it is assumed that the remaining life of the baseline unit is 6 years and would need to be replaced with another unit from the secondary market at that point.

DEEMED MEASURE COST

Non-IQ Participants:

Time of Sale: The incremental cost for this measure is assumed to be $40 for an ENERGY STAR unit and $261 for a CEE Tier 2 unit.[108]

Early Replacement: The measure cost is the full cost of removing the existing unit and installing a new one. The actual program cost should be used. If unavailable assume $448 for ENERGY STAR unit and $669 for CEE Tier 2 unit.[109]

The avoided replacement cost (after 4 years) of a baseline replacement unit is $447.[110] This cost should be discounted to present value using the nominal societal discount rate.

Income Qualified participants:

[104] ENERGY STAR Version 5.0 Room Air Conditioners Program Requirements
[105] See DOE's Appliance and Equipment Standards for Room AC.
[106] Measure Life Report, Residential and Commercial/Industrial Lighting and HVAC Measures, GDS Associates, June 2007.
[107] Standard assumption of one third of effective useful life.
[108] ENERGY STAR cost based on field study conducted by Efficiency Vermont and Tier 2 based on Efficiency Vermont's characterization of the NEEP Mid-Atlantic TRM's (version 9.0, October 2019) incremental cost analysis. See 'room-ac-cost-analysis-10.2023.xlsx.'
[109] ENERGY STAR based on IL PHA Efficient Living Program Data for 810 replaced units showing $416 per unit plus $32 average recycling/removal cost. Differential in cost for the CEE Tiers is $221, therefore CEE Tier 2 is $448 + 221 = $669.
[110] Estimate based upon Time of Sale incremental costs and applying inflation rate of 2.28% for 4 years.

The actual full cost of the ENERGY STAR unit should be used. If unavailable assume $300.[111] If a CEE Tier 2 unit is installed assume $508. The cost of the inefficient secondary market unit is assumed to be $50. Therefore, where the new unit replaces an existing unit the measure cost is $300 for ENERGY STAR or $508 for CEE Tier 2, and where there is no existing unit the measure cost is assumed to be $250 for ENERGY STAR or $458 for CEE Tier 2.

The avoided replacement cost (after 6 years) of the replacement secondary market unit is $50. This cost should be discounted to present value using the nominal societal discount rate.

LOADSHAPE

Loadshape R08 - Residential Cooling

COINCIDENCE FACTOR

For non-IQ participants, the coincidence factor for this measure is assumed to be 0.3.[112]

For Income Qualified units, where use is likely to be more consistent with central cooling, the summer peak coincidence factor is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)
= 68%[113]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)
= 46.6%[114]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Time of Sale: $\Delta kWh = (FLH_{RoomAC} * Btu/H * (1/CEERbase - 1/CEERee))/1000$

Early Replacment:

ΔkWh for remaining life of existing unit (1st 4 years) = $(FLH_{RoomAC} * Btu/H * (1/CEERexist - 1/CEERee))/1000$

ΔkWh for remaining measure life (next 8 years) = $(FLH_{RoomAC} * Btu/H * (1/CEERbase - 1/CEERee))/1000$

Where:

FLH_{RoomAC} = Full Load Hours of room air conditioning unit
= dependent on location:[115]

[111] To promote improved cost effectiveness, it is assumed that the lower cost ENERGY STAR Room AC units would be used. Units between $200-$400 are available dependent on capacity.

[112] Consistent with coincidence factors found in: RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008.

[113] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[114] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[115] Full load hours for room AC is significantly lower than for central AC. The average ratio of FLH for Room AC (provided in RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008) to FLH for Central Cooling for the same location is 31%. This ratio is applied to those IL cities that have FLH for Central Cooling provided in the ENERGY STAR calculator. For other cities this is extrapolated using the FLH assumptions VEIC have developed for Central AC. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

Climate Zone (City based upon)	Non- IQ Participants	IQ Participants		
	FLH_{RoomAC}	FLH_{RoomAC} (single family)	FLH_{RoomAC} (multifamily)	FLH_{RoomAC} (weatherized multifamily)[116]
1 (Rockford)	235	547	499	320
2 (Chicago)	261	709	629	403
3 (Springfield)	340	779	707	453
4 (Belleville)	447	1082	982	630
5 (Marion)	396	956	868	557
Weighted Average[117]				
ComEd	256	676	603	386
Ameren	364	875	791	507
Statewide	286	731	655	420

Btu/H = Size of rebated unit

= Actual. If unknown assume 8500 Btu/hr[118]

CEERexist = Combined Energy Efficiency Ratio of existing unit

= Actual (if existing unit has EER rating, convert to CEER by dividing by 1.01[119]). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time.[120] If unknown value is used, it should not be derated by age.

If unknown assume 8.7 CEER for IQ participants and 9.7 CEER for non-IQ or unknown[121]

CEERbase = Combined Energy Efficiency Ratio of baseline unit

= As provided in tables above for non-IQ participants. For IQ participants assume 9.7 CEER[122]

[116] *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015. The multifamily units within this study had undergone significant shell improvements (air sealing and insulation) and therefore this set of assumptions is only appropriate for units that have recently participated in a weatherization or other shell program. Note that the FLHcool where recalculated based on existing efficiencies consistent with the TRM rather than from the metering study.

[117] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[118] Based on maximum capacity average from the RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008

[119] This factor is used to appropriately compare with the new CEER rating which includes standby and off power consumption. Version 3.0 of the ENERGY STAR specification provided equivalent EER and CEER ratings and for the most popular size band the EER rating is approximately 1% higher than the CEER. See 'ENERGY STAR Version 3.0 Room Air Conditioners Program Requirements'.

[120] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[121] These units are likely to be the most inefficient existing units and so this assumption is lower than the estimate of the average Room AC. For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01) and for IQ participants this is professional judgement.

[122] The baseline unit for IQ customers is assumed to be purchased from the secondary market and is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

CEERee = Combined Energy Efficiency Ratio of CEE Tier 1 or ENERGY STAR unit

= Actual. If unknown, assume minimum qualifying standard as provided in tables above

Time of Sale:

For example, for an 8,500 Btu/H capacity unit, with louvered sides, in an unknown non IQ location:

$\Delta kWH_{ENERGY\ STAR}$ = (286 * 8500 * (1/10.9 – 1/14.7)) / 1000

= 57.7 kWh

For example, for an 8,500 Btu/H capacity unit, with louvered sides, in an unknown IQ location:

$\Delta kWh_{ENERGYSTAR}$ = (655 * 8500 * (1 /9.7 – 1 / 14.7)) / 1000

= 195.2 kWh

Early Replacement:

For example, a 7.7EER, 9000Btu/h unit is removed from a non-IQ home in Springfield and replaced with an ENERGY STAR unit with louvered sides:

ΔkWh for remaining life of existing unit (1st 4 years) = (340 * 9000 * (1/(7.7/1.01) - 1/14.7))/1000

= 193.2 kWh

ΔkWh for remaining measure life (next 8 years) = (340 * 9000 * (1/10.9 - 1/14.7))/1000

= 72.6 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Time of Sale: ΔkW = Btu/H * ((1/(CEERbase *1.01) - 1/(CEERee * 1.01)))/1000) * CF

Early Replacement: ΔkW = Btu/H * ((1/(CEERexist * 1.01) - 1/(CEERee * 1.01)))/1000) * CF

Where:

CF = Summer Peak Coincidence Factor for measure

For non-income qualified: = 0.3[123]

For income qualified:

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)
= 68%[124]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)
= 46.6%[125]

1.01 = Factor to convert CEER to EER (CEER includes standby and off power consumption)[126]

[123] Consistent with coincidence factors found in: RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008

[124] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[125] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[126] Since the new CEER rating includes standby and off power consumption, for peak calculations it is more appropriate to apply the EER rating, but it appears as though new units will only be rated with a CEER rating. Version 3.0 of the ENERGY STAR specification provided equivalent EER and CEER ratings and for the most popular size band the EER rating is approximately 1% higher than the CEER. See 'ENERGY STAR Version 3.0 Room Air Conditioners Program Requirements'.

Other variable as defined above

Time of Sale:

For example, for an 8,500 Btu/H capacity unit, with louvered sides, for an unknown non- IQ location:

ΔkW = ((8500 * (1/(10.9 * 1.01) – 1/(14.7*1.01))) / 1000) * 0.3

= 0.060 kW

For example, for an 8,500 Btu/H capacity unit, with louvered sides, in an unknown IQ location:

ΔkW_{SP} = (8500 * (1 /(9.7 * 1.01) – 1 /(14.7 * 1.01))) / 1000 * 0.68

= 0.2007 kW

Early Replacement:

For example, a 7.7 EER, 9000Btu/h unit is removed from a home in Springfield and replaced with an ENERGY STAR unit with louvered sides:

ΔkW for remaining life of existing unit (1st 4 years) = ((9000 * (1/7.7 - 1/(14.7 * 1.01)))/1000) * 0.3

= 0.169 kW

ΔkW for remaining measure life (next 8 years) = ((9000 * (1/(10.9 * 1.01) - 1/(14.7 * 1.01)))/1000) * 0.3

= 0.063 kW

5.1.8 Refrigerator and Freezer Recycling

DESCRIPTION

This measure describes savings from the retirement and recycling of inefficient but operational refrigerators and freezers. Savings are provided based on a 2013 workpaper provided by Cadmus that used data from a 2012 ComEd metering study and metering data from a Michigan study, to develop a regression equation that uses key inputs describing the retired unit. The savings are equivalent to the Unit Energy Consumption of the retired unit and should be claimed for the assumed remaining useful life of that unit. A part use factor is applied to account for those secondary units that are not in use throughout the entire year. The reader should note that the regression algorithm is designed to provide an accurate portrayal of savings for the population as a whole and includes those parameters that have a significant effect on the consumption. The precision of savings for individual units will vary.

For Net to Gross factor considerations, please refer to section 4.2 Appliance Recycling Protocol of Appendix A: Illinois Statewide Net-to-Gross Methodologies of Volume 4.0 Cross Cutting Measures and Attachments.

This measure was developed to be applicable to the following program types: ERET.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

N/A

DEFINITION OF BASELINE EQUIPMENT

The existing inefficient unit must be operational and have a capacity of between 10 and 30 cubic feet.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated remaining useful life of the recycling units is 6.5 years.[127]

DEEMED MEASURE COST

Measure cost includes the customer's value placed on their lost amenity, any customer transaction costs, and the cost of pickup and recycling of the refrigerator/freezer and should be based on actual costs of running the program. The payment (bounty) a Program Administrator makes to the customer serves as a proxy for the value the customer places on their lost amenity and any customer transaction costs. If unknown assume $170 per unit.[128]

LOADSHAPE

Loadshape R05 - Residential Refrigerator

COINCIDENCE FACTOR

The coincidence factor is assumed 1.081 for Refrigerators and 1.028 for Freezers[129].

[127] DOE refrigerator and freezer survival curves are used to calculate RUL for each equipment age and develop a RUL schedule. The RUL of each unit in the ARCA database is calculated and the average RUL of the dataset serves as the final measure RUL. Refrigerator recycling data from ComEd (PY7-PY9) and Ameren (PY6-PY8) were used to determined EUL with the DOE survival curves from the 2009 TSD. A weighted average of the retailer ComEd data and the Ameren data results in an average of 6.5 years. See Navigant 'ComEd Effective Useful Life Research Report', May 2018.

[128] The $170 default assumption is based on $120 cost of pickup and recycling per unit and $50 proxy for customer transaction costs and value customer places on their lost amenity. $120 is cost of pickup and recycling based on similar Efficiency Vermont program. $50 is bounty, based on Ameren and ComEd program offerings as of 7/27/15.

[129] Cadmus memo, February 12, 2013; "Appliance Recycling Update"

Algorithm

CALCULATION OF SAVINGS

ENERGY SAVINGS[130]

Refrigerators:

Energy savings for refrigerators are based upon a linear regression model using the following coefficients:[131]

Independent Variable Description	Estimate Coefficient
Intercept	83.324
Age (years)	3.678
Pre-1990 (=1 if manufactured pre-1990)	485.037
Size (cubic feet)	27.149
Dummy: Side-by-Side (= 1 if side-by-side)	406.779
Dummy: Primary Usage Type (in absence of the program) (= 1 if primary unit)	161.857
Interaction: Located in Unconditioned Space x CDD/365.25	15.366
Interaction: Located in Unconditioned Space x HDD/365.25	-11.067

ΔkWh = [83.32 + (Age * 3.68) + (Pre-1990 * 485.04) + (Size * 27.15) + (Side-by-side * 406.78) + (Proportion of Primary Appliances * 161.86) + (CDD/365.25 * unconditioned * 15.37) + (HDD/365.25 *unconditioned *-11.07)] * Part Use Factor

Where:

Age = Age of retired unit

Pre-1990 = Pre-1990 dummy (=1 if manufactured pre-1990, else 0)

Size = Capacity (cubic feet) of retired unit

Side-by-side = Side-by-side dummy (= 1 if side-by-side, else 0)

Primary Usage = Primary Usage Type (in absence of the program) dummy

(= 1 if Primary, else 0)

Interaction: Located in Unconditioned Space x CDD/365.25

(=1 * CDD/365.25 if in unconditioned space)

CDD = Cooling Degree Days

= Dependent on location:[132]

Climate Zone (City based upon)	CDD 65	CDD/365.25
1 (Rockford)	877	2.40

[130] Based on the specified regression, a small number of units may have negative energy and demand consumption. These are a function of the unit size and age, and should comprise a very small fraction of the population. While on an individual basis this result is counterintuitive it is important that these negative results remain such that as a population the average savings is appropriate.

[131] Energy savings are based on an average 30-year TMY temperature of 51.1 degrees. Coefficients provided in July 30, 2014 memo from Cadmus: "Appliance Recycling Update no single door July 30, 2014".

[132] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 65°F.

Climate Zone (City based upon)	CDD 65	CDD/365.25
2 (Chicago)	1047	2.87
3 (Springfield)	1183	3.24
4 (Belleville)	1641	4.49
5 (Marion/Murphysboro)	1450	3.97

Interaction: Located in Unconditioned Space x HDD/365.25

(=1 * HDD/365.25 if in unconditioned space)

HDD = Heating Degree Days

= Dependent on location:[133]

Climate Zone (City based upon)	HDD 65	HDD/365.25
1 (Rockford)	6414	17.56
2 (Chicago)	5963	16.33
3 (Springfield)	5368	14.70
4 (Belleville)	4162	11.39
5 (Marion/Murphysboro)	4413	12.08

Part Use Factor = To account for those units that are not running throughout the entire year. The most recent part-use factor participant survey results available at the start of the current program year shall be used.[134] For illustration purposes, this example uses 0.93.[135]

For example, the program averages for AIC's ARP in PY4 produce the following equation:

ΔkWh = [83.32 + (22.81 * 3.68) + (0.45 * 485.04) + (18.82 * 27.15) + (0.17 * 406.78) + (0.34 * 161.86) + (1.29 * 15.37) + (6.49 * -11.07)] * 0.93

= 969 * 0.93

= 900.9 kWh

Freezers:

Energy savings for freezers are based upon a linear regression model using the following coefficients:[136]

Independent Variable Description	Estimate Coefficient
Intercept	132.122
Age (years)	12.130
Pre-1990 (=1 if manufactured pre-1990)	156.181
Size (cubic feet)	31.839
Chest Freezer Configuration (=1 if chest freezer)	-19.709
Interaction: Located in Unconditioned Space x	9.778

[133] National Climatic Data Center, calculated from 1981-2010 climate normals with a base temp of 65°F.

[134] For example, the part-use factor that shall be applied to the current program year t (PYt) for savings verification purposes should be determined through the PYt-2 participant surveys conducted in the respective utility's service territory, if available. If an evaluation was not performed in PYt-2 the latest available evaluation should be used.

[135] Most recent refrigerator part-use factor from Ameren Illinois PY5 evaluation.

[136] Energy savings are based on an average 30-year TMY temperature of 51.1 degrees. Coefficients provided in January 31, 2013 memo from Cadmus: "Appliance Recycling Update".

Independent Variable Description	Estimate Coefficient
CDD/365.25	
Interaction: Located in Unconditioned Space x HDD/365.25	-12.755

ΔkWh = [132.12 + (Age * 12.13) + (Pre-1990 * 156.18) + (Size * 31.84) + (Chest Freezer * -19.71) + (CDDs* unconditioned *9.78) + (HDDs*unconditioned *-12.75)] * Part Use Factor

Where:

Age = Age of retired unit

Pre-1990 = Pre-1990 dummy (=1 if manufactured pre-1990, else 0)

Size = Capacity (cubic feet) of retired unit

Chest Freezer = Chest Freezer dummy (= 1 if chest freezer, else 0)

Interaction: Located in Unconditioned Space x CDD/365.25

(=1 * CDD/365.25 if in unconditioned space)

CDD = Cooling Degree Days (see table above)

Interaction: Located in Unconditioned Space x HDD/365.25

(=1 * HDD/365.25 if in unconditioned space)

HDD = Heating Degree Days (see table above)

Part Use Factor = To account for those units that are not running throughout the entire year. The most recent part-use factor participant survey results available at the start of the current program year shall be used.[137] For illustration purposes, the example uses 0.85.[138]

For example, the program averages for AIC's ARP in PY4 produce the following equation:

ΔkWh = [132.12 + (26.92 * 12.13) + (0.6 * 156.18) + (15.9 * 31.84) + (0.48 * -19.71) + (6.61 * 9.78) + (1.3 * -12.75)] * 0.825

= 977 * 0.825

= 905 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = kWh/8766 * CF

Where:

kWh = Savings provided in algorithm above

CF = Coincident factor defined as summer kW/average kW

= 1.081 for Refrigerators

= 1.028 for Freezers[139]

[137] For example, the part-use factor that shall be applied to the current program year t (PYt) for savings verification purposes should be determined through the PYt-2 participant surveys conducted in the respective utility's service territory, if available. If an evaluation was not performed in PYt-2 the latest available evaluation should be used.

[138] Most recent freezer part-use factor from Ameren Illinois Company PY5 evaluation.

[139] Cadmus memo, February 12, 2013; "Appliance Recycling Update"

For example, the program averages for AIC's ARP in PY4 produce the following equation:

ΔkW = 806/8766 * 1.081
= 0.099 kW

Note: No active programs utilizing this measure in IL as of 2023. Reliability update is required if measure if to be taken up again.

5.1.9 Room Air Conditioner Recycling

DESCRIPTION

This measure describes the savings resulting from running a drop off service taking existing residential, inefficient Room Air Conditioner units from service, prior to their natural end of life. This measure assumes that though a percentage of these units will be replaced this is not captured in the savings algorithm since it is unlikely that the incentive made someone retire a unit that they weren't already planning to retire. The savings therefore relate to the unit being taken off the grid as opposed to entering the secondary market. The Net to Gross factor applied to these units should incorporate adjustments that account for those participants who would have removed the unit from the grid anyway.

This measure was developed to be applicable to the following program types: ERET. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

N/A. This measure relates to the retiring of an existing inefficient unit.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is the existing inefficient room air conditioning unit.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed remaining useful life of the existing room air conditioning unit being retired is 4 years.[140]

DEEMED MEASURE COST

The actual implementation cost for recycling the existing unit should be used.

LOADSHAPE

Loadshape R08 - Residential Cooling

COINCIDENCE FACTOR

The non-IQ participants or unknown coincidence factor for this measure is assumed to be 30%.[141]

For Income Qualified units, where use is likely to be more consistent with central cooling, the summer peak coincidence factor is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)
= 68%[142]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)
= 46.6%[143]

[140] A third of assumed measure life for Room AC.
[141] Consistent with coincidence factors found in: RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008.
[142] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[143] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{(FLH_{RoomAC} * Btu/hr)}{EERexist * 1000}$$

Where:

FLH_{RoomAC} = Full Load Hours of room air conditioning unit

= dependent on location:[144]

Climate Zone (City based upon)	FLH_{RoomAC}			
	Non—Income Qualified (or Unknown)	Income Qualified single family	Income Qualified multifamily	Income Qualified weatherized multifamily [145]
1 (Rockford)	235	547	499	320
2 (Chicago)	261	709	629	403
3 (Springfield)	340	779	707	453
4 (Belleville)	447	1082	982	630
5 (Marion)	396	956	868	557
Weighted Average[146]				
ComEd	256	676	603	386
Ameren	364	875	791	507
Statewide	286	731	655	420

Btu/H = Size of retired unit

= Actual. If unknown assume 8500 Btu/hr [147]

CEERexist = Efficiency of existing unit

= Actual, if unknown assume 8.7 CEER for IQ participants and 9.7 CEER for non-IQ or unknown[148]

[144] Full load hours for room AC is significantly lower than for central AC. The average ratio of FLH for Room AC (provided in RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008) to FLH for Central Cooling for the same location is 31%. This ratio is applied to those IL cities that have FLH for Central Cooling provided in the ENERGY STAR calculator. For other cities this is extrapolated using the FLH assumptions VEIC have developed for Central AC. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[145] *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015. The multifamily units within this study had undergone significant shell improvements (air sealing and insulation) and therefore this set of assumptions is only appropriate for units that have recently participated in a weatherization or other shell program. Note that the FLHcool where recalculated based on existing efficiencies consistent with the TRM rather than from the metering study.

[146] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[147] Based on maximum capacity average from the RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008

[148] These units are likely to be the most inefficient existing units and so this assumption is lower than the estimate of the average Room AC. For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01) and for IQ participants this is professional judgement.

For example, for an 8500 Btu/h unit in Springfield from a non-IQ participant:

ΔkWh = (340 * 8500) / (9.7 * 1000)
= 298 kWh

For example, for an 8500 Btu/h unit in Springfield from a IQ single family participant:

ΔkWh = (779 * 8500) / (8.7 * 1000)
= 761 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \left(\frac{Btu/hr}{EERexist * 1000}\right) * CF$$

Where:

CF = Summer Peak Coincidence Factor for measure
= 0.3[149]

For example, an 8500 Btu/h unit in Springfield from a non-IQ participant:

ΔkW = (8500 / (9.7 * 1000)) * 0.3
= 0.2629 kW

For example, for an 8500 Btu/h unit in Springfield from a IQ single family participant:

ΔkW_{SSP} = (8500 / (8.7 * 1000)) * 0.68
= 0.6644 kW

RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008.

5.1.10 ENERGY STAR Clothes Dryer

DESCRIPTION

This measure relates to the installation of a residential clothes dryer meeting the ENERGY STAR[150] criteria. ENERGY STAR qualified clothes dryers save energy through a combination of more efficient drying and reduced runtime of the drying cycle. More efficient drying is achieved through heat pump technology, increased insulation, modifying operating conditions such as air flow and/or heat input rate, improving air circulation through better drum design or booster fans, and improving efficiency of motors. Reducing the runtime of dryers through automatic termination by temperature and moisture sensors is believed to have the greatest potential for reducing energy use in clothes dryers[151]. ENERGY STAR provides criteria for both gas and electric clothes dryers.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Clothes dryer must meet the ENERGY STAR or ENERGY STAR Most Efficient criteria, as required by the program. Units utilizing the Heat Pump designation must meet the same ENERGY STAR criteria and be classified as Heat Pump or Hybrid Heat Pump units.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a clothes dryer meeting the minimum federal requirements for units manufactured on or after January 1, 2015. Note that the DOE Federal Standards utilize the Appendix D1 testing procedure whereas the ENERGY STAR specifications use the Appendix D2 test. In order to compare relative efficiencies, this measure uses adjusted baseline CEF values that were developed by ENERGY STAR to convert CEF-D1 values in to equivalent CEF-D2 values.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 16 years.[152]

DEEMED MEASURE COST

For non-IQ participants, the incremental cost for an ENERGY STAR clothes dryer is assumed to be $152 and $405 for an ENERGY STAR Most Efficient dryer.[153]

For IQ participants, the incremental cost for an ENERGY STAR clothes dryer is assumed to be $246 and $499 for an ENERGY STAR Most Efficient dryer. [154]

Any additional installation costs resulting from fuel switch/electrification measures (such as upgrading electrical panels, capping existing gas lines or adding new electrical circuits) should be divided across all applicable measures weighted by total MMBtu savings.

[150] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[151] ENERGY STAR Market & Industry Scoping Report. Residential Clothes Dryers. Table 8. November 2011.
[152] Based on DOE Rulemaking Technical Support Document, LCC Chapter, 2011, as recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.
[153] Based on the difference in installed cost for an efficient dryer ($716) and standard dryer ($564) (see "ACEEE Clothes Dryers.pdf").
[154] IQ Incremental costs factor in the assumption that a secondhand unit costs on average 50% of a new baseline unit, and that 1/3 of IQ participants would have purchased a unit on the secondhand market. See "IQ Appliance Calculations.xls" for information.

LOADSHAPE

Loadshape R17 - Residential Electric Dryer

COINCIDENCE FACTOR

The coincidence factor for this measure is 3.8%.[155]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Non Fuel Switch Measures

$$\Delta kWh = ((Load/CEFbase * IQAdj) – Load/CEFeff) * Ncycles * \%Electric$$

$$\Delta Therm = ((Load/CEFbase * IQAdj) – Load/CEFeff) * Ncycles * Therm_convert * \%Gas$$

Fuel Switch/Electrification Measures

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

SiteEnergySavings (MMBTUs) = [FuelSwitchSavings] + [NonFuelSwitchSavings]

FuelSwitchSavings = $[((Load/CEFbase_{Gas} * IQAdj) * Ncycles * MMBtu_convert * \%Gas_{Gas}] - [Load/CEFeff_{Elec} * Ncycles * MMBtu_convert * \%Gas_{Gas}]$

NonFuelSwitchSavings = $[((Load/CEFbase_{Gas} * IQAdj) * Ncycles * MMBtu_convert * \%Electric_{Gas}] - [Load/CEFeff_{Elec} * Ncycles * MMBtu_convert * \%Electric_{Gas}]$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:

Load = The average total weight (lbs) of clothes per drying cycle. If dryer size is unknown, assume standard.

[155] Based on coincidence factor of 3.8% for clothes washers

Dryer Size	Load (lbs)[156]
Standard	8.45
Compact	3

CEFbase = Combined energy factor (CEF) (lbs/kWh) of the baseline unit is based on existing federal standards energy factor and adjusted to CEF-D2 (equivalent to as if tested under Appendix D2) as performed in the ENERGY STAR analysis.[157] If product class unknown, assume electric, standard.

Product Class	CEF (lbs/kWh) under Appendix D2
Vented Electric, Standard (≥ 4.4 ft^3)	3.11
Vented Electric, Compact (120V) (< 4.4 ft^3)	3.01
Vented Electric, Compact (240V) (<4.4 ft^3)	2.73
Ventless Electric, Compact (240V) (<4.4 ft^3)	2.13
Vented Gas	2.84[158]
Electric Heat Pump, Standard (≥ 4.4 ft^3)	3.11
Electric Heat Pump, Compact (120V) (< 4.4 ft^3)	3.01

IQAdj = Baseline consumption adjustment for IQ program participants to account for a portion of participants who would have utilized the secondary market. [159]

= 1.033 if IQ, 1.0 if non-IQ

CEFeff = CEF (lbs/kWh) of the ENERGY STAR unit based on ENERGY STAR or ENERGY STAR Most Efficient requirements.[160]

= Actual. If unknown, use defaults below. If product class unknown, assume electric, standard.

	ENERGY STAR	ENERGY STAR Most Efficient
Product Class	CEF (lbs/kWh)	CEF (lbs/kWh)
Vented or Ventless Electric, Standard (≥ 4.4 ft^3)	3.93	4.3
Vented or Ventless Electric, Compact (120V) (< 4.4 ft^3)	3.80	4.3
Vented Electric, Compact (240V) (< 4.4 ft^3)	3.45	4.3
Ventless Electric, Compact (240V) (< 4.4 ft^3)	2.68	3.7

[156] Based on ENERGY STAR test procedures.
[157] ENERGY STAR Draft 2 Version 1.0 Clothes Dryers Data and Analysis
[158] Federal standards report CEF for gas clothes dryers in terms of lbs/kWh. To determine gas savings, this number is later converted to therms.
[159] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (11 years). The current Federal Standard became effective in 2015 so the previous standard is used to estimate base consumption for a second hand unit, and further increased by an estimate of 0.4% * 11 years (based on review of the refrigerator/freezer regression algorithm used in the 5.1.8 Refrigerator and Freezer Recycling measure) to account for degradation of performance over time. This second hand consumption was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.
[160] ENERGY STAR Clothes Dryers Key Product Criteria.

	ENERGY STAR	ENERGY STAR Most Efficient
Product Class	CEF (lbs/kWh)	CEF (lbs/kWh)
Vented Gas	3.48[161]	3.8
Electric Heat Pump, Standard (≥ 4.4 ft^3)	3.93	6.5[162]
Electric Heat Pump, Compact (< 4.4 ft^3)	3.36	6.2[163]

Ncycles = Number of dryer cycles per year. Use actual data if available. If unknown, use 259 cycles per year.[164]

%Electric = The percent of overall savings coming from electricity

= 100% for electric dryers, 16% for gas dryers[165]

Therm_convert = Conversion factor from kWh to Therm

= 0.03412

%Gas = Percent of overall savings coming from gas

= 0% for electric units and 84% for gas units[166]

MMBtu_convert = Conversion factor from kWh to MMBtu

= 0.003412

[161] Federal standards report CEF for gas clothes dryers in terms of lbs/kWh. To determine gas savings, this number is later converted to therms.

[162] Average CEF of available standard ENERGY STAR Clothes Dryers with Heat Pump technology. EPA ENERGY STAR. May 2022. https://www.energystar.gov/productfinder/product/certified-clothes-dryers/.

[163] Average CEF of available compact ENERGY STAR Clothes Dryers with Heat Pump technology. EPA ENERGY STAR. May 2022. https://www.energystar.gov/productfinder/product/certified-clothes-dryers/.

[164] Loads per week was estimated by taking the weighted average of the number of loads per week (midpoint used where loads per week is a range and the weights are the share of respondents falling into each number of loads per week response bin). This estimate was scaled to an IL-specific value by applying a ratio developed using the 2009 state specific values for the states in the East North Central portion of the Midwest Region. Reduced by 6% to maintain prior ratio of dryer to clothes washer loads of 94%.

[165] %Electric accounts for the fact that some of the savings on gas dryers comes from electricity (motors, controls, etc). 16% was determined using a ratio of the electric to total savings from gas dryers given by ENERGY STAR Draft 2 Version 1.0 Clothes Dryers Data and Analysis.

[166] %Gas accounts for the fact that some of the savings on gas dryers comes from electricity (motors, controls, etc). 84% was determined using a ratio of the gas to total savings from gas dryers given by ENERGY STAR Draft 2 Version 1.0 Clothes Dryers Data and Analysis.

Electric examples, for a non- IQ Time of Sale, standard, vented, electric ENERGY STAR clothes dryer:

ΔkWh = (((8.45/3.11 * 1) – 8.45/3.93) * 259 * 100%)
= 147 kWh

For an IQ Time of Sale, standard, vented, electric ENERGY STAR clothes dryer:

ΔkWh = (((8.45/3.11 * 1.033) – 8.45/3.93) * 259 * 100%)
= 170 kWh

Gas example, for a non-IQ Time of Sale, a standard, vented, gas ENERGY STAR clothes dryer:

ΔTherm = ((8.45/2.84 * 1) – 8.45/3.48) * 259 * 0.03412 * 0.84
= 4.06 therms

ΔkWh = (((8.45/2.84 * 1) – 8.45/3.48) * 259 * 0.16)
= 22.7 kWh

Fuel switch example, for a non-IQ Time of Sale, ENERGYSTAR Most Efficient Heat Pump clothes dryer in place of a baseline gas dryer:

SiteEnergySavings (MMBTUs) = [FuelSwitchSavings] + [NonFuelSwitchSavings]

FuelSwitchSavings = [((Load/CEFbase$_{Gas}$ * IQAdj) * Ncycles * MMBtu_convert * %Gas$_{Gas}$] - [Load/CEFeff$_{Elec}$ * Ncycles * MMBtu_convert * %Gas$_{Gas}$]

= ((8.45/2.84 * 1) * 259 * 0.003412 * 0.84) - (8.45/5.7 * 259 * 0.003412 * 0.84)

= 1.11 MMbtu

NonFuelSwitchSavings = [((Load/CEFbase$_{Gas}$ * IQAdj) * Ncycles * MMBtu_convert * %Electric$_{Gas}$] - [Load/CEFeff$_{Elec}$ * Ncycles * MMBtu_convert * %Electric$_{Gas}$]

= ((8.45/2.84 * 1) * 259 * 0.003412 * 0.16) - (8.45/5.7 * 259 * 0.003412 * 0.16)

= 0.21 MMBtu

SiteEnergySavings (MMBTUs) = 1.11 + 0.21
= 1.32 MMBtu

If supported by an electric utility: ΔkWh = ΔSiteEnergySavings * 1,000,000 / 3,412
= 1.32 * 1,000,000/3412
= 386.9 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

For non-fuel switch measures:

ΔkW = (((Load/CEFbase * IQAdj) – Load/CEFeff) * Ncycles * %Electric)/Hours * CF

For fuel switch measures:

$$\Delta kW = ([(Load/CEFBase_{Gas} * IQAdj) * Ncycles * \%Electric_{Gas}] - [Load/CEFeff_{Elec} * Ncycles * \%Electric_{Electric}])/Hours * CF$$

Where:

Hours = Annual run hours of clothes dryer. Use actual data if available. If unknown, use 259 hours per year.[167]

CF = Summer Peak Coincidence Factor for measure

= 3.8%[168]

For example, for a non-IQ Time of Sale, standard, vented, electric ENERGY STAR clothes dryer:

ΔkW = (((8.45/3.11 * 1) – 8.45/3.93) * 259 * 100%)/259 * 3.8%

= 0.0215 kW

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

WATER IMPACT DESCRIPTIONS AND CALCULATION

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below) adjusted for utility line losses (at-the-busbar savings), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, this will not match the output of the calculation/allocation methodology presented in the "Electric Energy Savings" and "Fossil Fuel Savings" sections above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = [Gas Dryer Consumption Replaced]

$$= [((Load/CEFbase_{Gas} * IQAdj) * Ncycles * Therm_convert * \%Gas_{Gas}]$$

ΔkWh = [Gas Dryer Electric Consumption Replaced] - [Electric Dryer Consumption Added]

$$= [(Load/CEFbase_{Gas} * IQAdj) * Ncycles * \%Electric_{Gas}] - [Load/CEFeff_{Elec} * Ncycles * \%Electric_{Electric}]$$

[167] ENERGY STAR qualified dryers have a maximum test cycle time of 80 minutes. Assume one hour per dryer cycle.

[168] Based on coincidence factor of 3.8% for clothes washers.

REVIEW DEADLINE: 1/1/2029

5.1.11 ENERGY STAR Water Coolers

DESCRIPTION

Water coolers are a home appliance that offer consumers the ability to enjoy hot and/or cold water on demand. This measure is the characterization of the purchasing and use of an ENERGY STAR[169] certified water cooler in place of a conventional water cooler.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The high efficiency equipment is an ENERGY STAR certified water cooler meeting the ENERGY STAR 3.0 efficiency criteria.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a standard or conventional, non-ENERGY STAR certified water cooler.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated useful life for a water cooler is 10 years.[170]

DEEMED MEASURE COST

The incremental cost for this measure is estimated at $60.[171]

LOADSHAPE

Loadshape C53: Flat

COINCIDENCE FACTOR

The summer peak coincidence factor is assumed to be 1.0.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (kWh_{base} - kWh_{ee}) * Days$$

Where:

kWh_{base} = Daily energy use (kWh/day) for baseline water cooler[172]

Type of Water Cooler	kWhbase
Hot and Cold Water – Storage	0.875
Hot and Cold Water – On Demand	0.811
Cold Water Only	0.826

[169] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

kWh_{ee} = Daily energy use (kWh/day) for ENERGY STAR water cooler[173]

Type of Water Cooler	kWhee
Hot and Cold Water – Storage	0.689
Hot and Cold Water – On Demand	0.138
Cold Water Only	0.139

Days = Number of days per year that the water cooler is in use
= 365 days[174]

Energy Savings:

Type of Water Cooler	ΔkWh
Hot and Cold Water – Storage	68.2
Hot and Cold Water – On Demand	245.7
Cold Water Only	250.8

DEMAND SAVINGS

ΔkW = ΔkWh / Hours * CF

Where:

Hours = Number of hours per year water cooler is in use
= 8760 hours[175]

CF = Summer Peak Coincidence Factor for measure

= 1.0

Demand Savings:

Type of Water Cooler	ΔkW
Hot and Cold Water - Storage	0.0078
Hot and Cold Water – On Demand	0.0280
Cold Water Only	0.0286

5.1.12 Ozone Laundry

DESCRIPTION

A new ozone laundry system is added-on to new or existing residential clothes washing machine(s) or washing machines located in multifamily building common areas. The system generates ozone (O_3), a naturally occurring molecule, which helps clean fabrics by chemically reacting with soils in cold water. Adding an ozone laundry system(s) eliminate the use of chemicals, detergents, and hot water by residential washing machine(s).

Energy savings will be achieved at the domestic hot water heater as it will no longer supply hot water to the washing machine. Cold water usage by the clothes washer will increase, but overall water usage will stay constant.

This measure was developed to be applicable to the following program types: TOS, RNC, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

A new, single-unit ozone laundry system(s) rated for residential clothes washing machines is added-on to new or existing residential clothes washing machines. The ozone laundry system must be connected to both the hot and cold water inlets of the clothes washing machine so that hot water from the domestic hot water heater is no longer provided to the clothes washer.

The ozone laundry system(s) must transfer ozone into the water through:

- Venturi injection
- Bubble diffusion
- Additional applications may be considered upon program review and approval on a case by case basis

DEFINITION OF BASELINE EQUIPMENT

The base case equipment is a conventional residential washing machine with no ozone generator installed. The washing machine is provided hot water from a domestic hot water heater.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure equipment effective useful life (EUL) is estimated at 8 years based on the typical lifetime of products currently available in the market.[176]

DEEMED MEASURE COST

The deemed measure cost is $300 for a new single-unit ozone laundry system.[177]

LOADSHAPE

Loadshape R01 – Residential Clothes Washer

COINCIDENCE FACTOR

The coincidence factor for this measure is 3.8%.[178]

[176] Average based on conversations with manufacturers and distributors of the four residential ozone laundry systems tested in the 2018 GTI Residential Ozone Laundry Field Demonstration (O3 Pure, Pure Wash, Eco Washer, Scent Crusher).
[177] 2018 GTI Residential Ozone Laundry Field Demonstration (May 2018).
[178] Calculated from Itron eShapes, 8760 hourly data by end use for Missouri, as provided by Ameren.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = kWhHotWash * (\%HotWash_{base} - \%HotWash_{Ozone})$$

Where:

kWhHotWash = (%ElectricDHW * Capacity * IWF * %HotWater * (T_{OUT} - T_{IN}) * 8.33 * 1.0 * Ncycles) / (RE_electric * 3.412)

%ElectricDHW = Proportion of water heating supplied by electric heating

= 100 % for Electric

= 0 % for Fossil Fuel

= If unknown[179], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	19.7%	30.6%	63.3%	67.3%	31.4%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
People's Gas	2.1%	2.0%	1.7%	2.4%	2.2%
Northshore Gas	1.5%	1.8%	10.0%	2.4%	2.4%
Nicor Gas	7.6%	9.9%	14.4%	22.6%	10.0%
All DUs[180]					**29%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Capacity = Clothes washer capacity (cubic feet).

= Actual. If unknown, assume 5.0 cubic feet.[181]

IWF = Integrated water factor (gallons/cycle/ft^3).

= Actual. If unknown, use the following values

Efficiency Level	IWF (gallons/cycle/ft3)	
	Top loading > 2.5 Cu ft	Front Loading > 2.5 Cu ft
Federal Standard (up to January 1, 2018)	8.4	4.7
Federal Standard (after January 1, 2018) – Use if unit level is unknown.	6.5	4.7

[179] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[180] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[181] Average data from GTI Residential Ozone Laundry Field Demonstration (May 2018). As an add on to existing equipment it is assumed this is a larger capacity than the assumption for new Clothes Washers as old machines tended to have larger capacities. See 'Residential Ozone Summary Calcs_2019.xlsx' and 'Multifamily Ozone Summary Calcs_2019.xlsx' for more information. If utilities have specific evaluation results providing a more appropriate assumption for homes in a particular market or geographical area then that should be used.

Efficiency Level	IWF (gallons/cycle/ft3)	
	Top loading > 2.5 Cu ft	Front Loading > 2.5 Cu ft
ENERGY STAR (as of February 2018)	4.3	3.2
CEE Tier 2	3.2	3.2

%HotWater = Percentage of water usage that is supplied by the domestic hot water heater when the hot or warm wash cycles are selected.[182]

Single-Family Home	Multifamily
0.1759	0.2960

T_{OUT} = Tank temperature

= 125°F

T_{IN} = Incoming water temperature from well or municipal system

= 50.7°F [183]

8.33 = Specific weight of water (lbs/gallon)

1.0 = Heat capacity of water (Btu/lb °F)

Ncycles = Number of Cycles per year

Single-Family Home	Multifamily
276[184]	1,243[185]

RE_electric = Recovery efficiency of electric water heater

= 0.98[186] for Electric Resistance

= 3.51[187] for Electric HPWH

3412 = Btus to kWh conversion (Btu/kWh)

$\%HotWash_{base}$ = Average percentage of loads that use hot or warm water with baseline equipment. [188]

[182] Averaged data from GTI Residential Ozone Laundry Field Demonstration (May 2018). Hot and warm wash cycles were combined because data from the EIA Residential Energy Consumption Survey (RECS) 2015 East North Central Region show that, of the total hot and warm washes that occur, over 96% are warm washes. See 'Residential Ozone Summary Calcs_2019.xlsx' and 'Multifamily Ozone Summary Calcs_2019.xlsx' for more information.

[183] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[184] Loads per week was estimated by taking the weighted average of the number of loads per week (midpoint used where loads per week is a range and the weights are the share of respondents falling into each number of loads per week response bin). This estimate was scaled to an IL-specific value by applying a ratio developed using the 2009 state specific values for the states in the East North Central portion of the Midwest Region.
If utilities have specific evaluation results providing a more appropriate assumption for single-family or Multifamily homes, in a particular market, or geographical area then that should be used.

[185] DOE Technical Support Document Chapter 6, 2010 https://www.regulations.gov/contentStreamer?documentId=EERE-2006-STD-0127-0118&attachmentNumber=8&disposition=attachment&contentType=pdf

[186] Review of AHRI database shows that electric water heaters have a recovery efficiency of 98%.

[187] Review of AHRI database shows that Electric Heat Pump Water Heaters support this recovery efficiency. For the raw data, and calculations, please see AHRI_ RES Water Heaters 2022.xlsx.

[188] GTI Residential Ozone Laundry Field Demonstration (May 2018). See 'Residential Ozone Summary Calcs_2019.xlsx' and 'Multifamily Ozone Summary Calcs_2019.xlsx' for more information.

Single-Family Home	Multifamily
0.7743	0.7438

$\%HotWash_{Ozone}$ = Percentage of loads that use hot or warm water with efficient equipment.

= 0.0

For example, a residential ozone laundry system is installed in a single-family home with an electric domestic hot water heater. The capacity and IWF of the baseline equipment is unknown.

ΔkWh = (1 * 5.0 * 6.5 * 0.1759 * (125 – 50.7) * 8.33 * 1.0 * 276) / (0.98 * 3,412) * (0.7743 – 0)

= 226 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh/Hours * CF

Where:

ΔkWh = Energy Savings as calculated above

Hours = Assumed Run hours of Clothes Washer[189]

Single-Family Home	Multifamily
276	1,243

CF = Summer Peak Coincidence Factor for measure.

= 0.038[190]

For example, a residential ozone laundry system is installed in a single-family home with an electric domestic hot water heater. The capacity and IWF of the baseline equipment is unknown.

ΔkW = 226/276 * 0.038

= 0.0311kW

FOSSIL FUEL SAVINGS

$\Delta Therm = ThermHotWash * (\%HotWash_{base} - \%HotWash_{Ozone})$

Where:

ThermHotWash = (%FossilDHW * Capacity * IWF * %HotWater * (T_{OUT} - T_{IN}) * 8.33 * 1.0 * Ncycles) / (RE_gas * 100,000)

%FossilDHW = Percentage of DHW savings assumed to be fossil fuel

= 100 % for Fossil Fuel

= 0 % for Electric

= If unknown[191], use the following table:

[189] Based on a weighted average of 276 clothes washer cycles per year assuming an average load runs for one hour.

[190] Calculated from Itron eShapes, 8760 hourly data by end use for Missouri, as provided by Ameren.

[191] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs[192]					**71%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

RE_gas = Recovery efficiency of gas water heater

Single-Family Homes	Multifamily
79%[193]	67%[194]

100,000 = Btus to Therms conversion (Btu/Therm).

For example, a residential ozone laundry system is installed in a single-family home with a gas domestic hot water heater. The capacity and IWF of the baseline equipment is unknown.

ΔTherms = (1 * 5.0 * 6.5 * 0.1759 * (125 – 50.7) * 8.33 * 1.0 * 276)/(0.79 * 100,000)*(0.7743 – 0)

= 9.6 Therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

LAUNDRY DETERGENT SAVINGS

Annual savings from not purchasing laundry detergent that are realized by efficient equipment end-user(s) ($/year).

Detergent savings per year = Detergent_cost * Ncycles

Where:

Detergent_cost = Average laundry detergent cost per load ($/load).

[192] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

[193] DOE Final Rule discusses Recovery Efficiency with an average around 0.76 for Gas Fired Storage Water heaters and 0.78 for standard efficiency gas fired tankless water heaters up to 0.95 for the highest efficiency gas fired condensing tankless water heaters. These numbers represent the range of new units however, not the range of existing units in stock. Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 79%.

[194] Water heating in Multifamily buildings is often provided by a larger central boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of 0.59 and the 0.75 for single family homes. An average efficiency of 0.67 is used for this analysis as a default for Multifamily buildings.

= 0.16[195]

For example, a residential ozone laundry system is installed in a single-family home.

Detergent savings per year = 0.16 * 276

= $44.16

MEASURE CODE: RS-APL-OZNE-V08-260101

REVIEW DEADLINE: 1/1/2030

[195] Based on cost analysis of products available on www.Jet.com and www.Amazon.com.

5.1.13 Income Qualified: ENERGY STAR and CEE Tier 2 Room Air Conditioner - Retired 12/31/2014

Measure combined with 5.1.7 ENERGY STAR and CEE Tier 2 Room Air Conditioner.

5.1.14 Residential Induction Cooking Appliances

DESCRIPTION

A fully electric range with an electric oven and an induction cooktop or a freestanding induction cooktop installed in place of an electric range with an electric resistance cooktop, natural gas range, or a freestanding electric resistance cooktop.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as a freestanding cooktop that heats cooking vessels using electrical induction or a range with an electric resistance oven and an electric induction cooktop for residential applications. The integrated annual energy consumption (IAEC) represents both the active and standby operating mode energy consumption across one year of operation.[196]

DEFINITION OF BASELINE EQUIPMENT

The baseline product is a minimally efficient electric resistance or gas cooktop.

Cooktop Type	IAEC (Electric) and AEC (Gas)[197]
Electric Resistance	236.9 kWh/year
Natural Gas	1,900 kBtu/year

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of the measure is 16 years.[198]

DEEMED MEASURE COST

The incremental measure cost for an electric range with an induction cooktop is $1,490 when compared to an electric range with an electric resistance cooktop and $1,494 when compared to a gas range. The incremental measure cost for a freestanding induction cooktop is $764 when compared to a freestanding electric resistance cooktop and $880 when compared to a freestanding natural gas cooktop.[199] Assume $100 additional labor from an electric baseline to install additional power/socket requirements.[200] An additional $530 in parts and labor costs are required when replacing a natural gas range or freestanding cooktop to account for infrastructure costs to install electrical wiring, receptacles, circuit breaker, and to cap the gas line.[201]

[196] IAEC is calculated for products tested per Methodology in 10 CFR 430, Subpart B, Appendix I1 - Uniform Test Method for Measuring the Energy Consumption of Conventional Cooking Products

[197] The U.S. DOE Notice of Proposed Rulemaking (NOPR) Technical Support Document (TSD): https://www.regulations.gov/document/EERE-2014-BT-STD-0005-0090, provides the baseline IAEC for electric-coil cooktops of 199 kWh/year. The U.S. DOE Direct Final Rule (DFR) TSD: https://www.regulations.gov/document/EERE-2014-BT-STD-0005-12819, provides the baseline IAEC for electric-smooth non-induction cooktops of 250 kWh/year and gas cooktops. The DFR TSD also provides the market distribution of electric-smooth versus electric-coil products, at 74.4% and 25.6% respectively.

[198] The EUL was developed for the U.S. Department of Energy (DOE) Energy Conservation Program, Energy Conservation Standards for Residential Conventional Cooking Products as part of the 2016 supplemental notice of proposed rulemaking (SNOPR).

[199] Measure materials cost references market price data from San Diego Gas & Electric (SDG&E). 2024 "SWAP015 Cost Analysis_2024-10-09.xlsx. for electric cooktops and ranges and data from "SWAP013 Cost Analysis_2024-10-03.xlsx." for natural gas cooktops and ranges. Prices do not include additional costs for induction cookware. Baseline equipment cost references U.S. Department of Energy document EERE-2014-BT-STD-0005-12819. All prices were adjusted according to the Bureau of Labor Statistics Consumer Price Index rate to account for inflation and materials and labor rates for the Chicago region in 2026.

[200] Additional labor cost is an estimate.

[201] Infrastructure costs based on R.S. Means material and labor cost data for the installation of residential ranges and cooktops and the installation of electrical components required when switching from natural gas to electric fuel.

Any additional installation costs resulting from fuel switch/electrification measures (such as upgrading electrical panels, capping existing gas lines or adding new electrical circuits) should be divided across all applicable measures weighted by total MMBtu savings.

LOADSHAPE

Loadshape R20 – Residential Induction Cooktop

COINCIDENCE FACTOR

The coincidence factor is assumed to be 29%.[202]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS

Non Fuel Switch Measures (baseline is electric cooktop or range)

$$\Delta kWh = CooktopIAECbase - CooktopIAECee$$

Fuel switch measure (baseline is natural gas cooktop or range):

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

$$\Delta SiteEnergySavings\ (MMBtu) = [\Delta CookingSavings] + [HVACImpacts]$$

$$\Delta CookingSavings = FuelSwitchSavings + NonFuelSwitchSavings$$

$$FuelSwitchSavings = [GasConsumptionReplaced] - [ElectricConsumptionAdded]$$

$$NonFuelSwitchSavings = [ElectricConsumptionReplaced]$$

$$GasConsumptionReplaced = \frac{AECbaseGas}{10}$$

$$ElectricConsumptionAdded = \frac{IAECee * 3{,}412}{1{,}000{,}000}$$

$$ElectricConsumptionReplaced = \frac{AECbaseElectric * 3{,}412}{1{,}000{,}000}$$

$$HVACImpacts\ [counted\ as\ nonfuel\ switch\ savings] = [CoolingImpact] - [ElecHeatImpact] - [FuelHeatImpact]$$

$$CoolingImpact = \frac{\Delta CookingSavings * \%Cool * HCFCOOL * VentFactor}{COPCOOL}$$

$$ElecHeatImpact = \frac{\Delta CookingSavings * \%ElectricHeat * HCFHEAT * VentFactor}{COPHEAT}$$

[202] Calculated from ResStock, 15 minute interval data by end use for Illinois, as provided by NREL.

$$FuelHeatImpact = \frac{\Delta CookingSavings * \%FossilHeat * HCFHEAT * VentFactor}{\eta Heat}$$

If ΔSiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	ΔSiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * ΔSiteEnergySavings * 1,000,000/3,412	%IncentiveGas * ΔSiteEnergySavings * 10
Gas utility only	N/A	ΔSiteEnergySavings * 10

Where:

$CooktopIAEC_{ee}$ = Integrated Annual Energy Consumption of an induction cooktop in kWh/yr

= Actual if IAEC is known, if unknown assume 184.2 kWh/yr[203].

$CooktopIAEC_{baseElec}$ = Integrated Annual Energy Consumption of a baseline electric cooktop in kWh/yr

= If values unknown, assume 236.9 kWh/yr

$IAEC_{ee}$ = Integrated Annual Energy Consumption of induction cooking appliance in kWh/yr

= $CooktopIAEC_{ee}$ + $OvenIAEC_{ee}$

$OvenIAEC_{ee}$ = Annual Energy Consumption of electric oven in kWh/yr

= 0 for standalone cooktop appliances

For ranges, if actual $OvenIAEC_{ee}$ is unknown, assume a value of 330 kWh/yr[204]

$AEC_{baseElec}$ = Annual Electric Energy Consumption of baseline electric cooking appliance in kWh/yr, for standby and ignition energy

= 0 for standalone cooktop appliances

For ranges, if $AEC_{baseElec}$ is unknown, assume a value of 4.1 kWh/yr[205]

$AEC_{baseGas}$ = Annual Energy Consumption of a baseline gas cooking appliance in therms/yr

[203] The U.S. Environmental Protection Agency (EPA) provided induction cooktop test data in their 2024 ENERGY STAR specification development process. Ten induction cooktops – seven as standalone cooktops and three as the cooktop portion of a range – were at or more efficient than the adopted ENERGY STAR specification level. The average IAEC of those 10 ENERGY STAR qualifying products was 184.2 kWh/year.

[204] The U.S. DOE Direct Final Rule (DFR) TSD: https://www.regulations.gov/document/EERE-2014-BT-STD-0005-12819, provides the baseline IAEC for all variations of oven energy consumption for both gas and electric units as well as the market share allocated between each variation.

[205] Ibid. Average of test data. Average taken as there is no clear correlation between standby energy consumption and active mode energy consumption among the DOE published test data.

= $CooktopAEC_{baseGas}$ + $OvenAEC_{baseGas}$

$CooktopAEC_{baseGas}$ = Annual Energy Consumption of baseline gas cooktop in therms/yr

If unknown, assume 19 therms[206]

$OvenAEC_{baseGas}$ = Annual Energy Consumption of baseline gas oven in therms/yr

= 0 for standalone cooktop appliances

For ranges, if actual $OvenAEC_{baseGas}$ is unknown, assume a value of 20 therms[207].

%ElectricHeat = Percentage of homes that have electric heating

= 100% if electrically heated home, 0% if gas, or

= If unknown[208], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[209]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

%FossilHeat = Percentage of homes that have fossil fuel heating

= 100% if fossil heated home, 0% if electric, or

= If unknown[210], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%

[206] DOE 2024 Direct Final Rule assumes a baseline IAEC of 1,900 kBtu/year, equivalent to roughly 19 therms/year for standalone gas cooktop usage.

[207] DOE 2024 Direct Final Rule calculates an integrated annual energy consumption (IEAO) for ovens of 20 therms/year when taking a weighted average of all four electric oven configuration (Standards versus Self-Clearn and Freestanding versus Built-in) baseline scenarios and subtracting the average standby power of all DOE published tested products.

[208] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[209] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[210] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[211]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

%Cool = Percent of homes that have cooling

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[212]	98.9%	96.5%	99.8%	98.7%	98.6%

HCF_{COOL} = 21%, Portion of reducted waste heat that is coincident with home cooling load[213]

VentFactor = 50%[214]

COP_{COOL} = COP of central air conditioning

= Assume 2.8 if unknown[215]

HCF_{HEAT} = 34.8%, portion of reduced waste heat that is coincident with home heating load[216]

COP_{HEAT} = COP of electric heating system

[211] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

[212] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[213] Additional cooling savings from HVAC interactive effects of 21% of appliance savings, estimated using average result from BEOPT simulation modeling comparing two different home configurations and two locations. Ratio compares the changes in home HVAC loads to changes in appliance energy consumption.

[214] This factor approximates the effectiveness of kitchen ventilation systems in exhausting waste heat from the home. Reference reviewed include 1. Kile et al. Environmental Health 2014, 13:71 (http://www.ehjournal.net/content/13/1/71) which showed 221 of 445 surveyed used exhaust during cooktop cooking; also 2. Cooking Appliance Use in CA Homes. Victoria L. Klug, Agnes B. Lobscheid, Brett C. Singer Environmental Energy Technologies Division Lawrence Berkeley National Laboratory, Berkeley, California, USA August 2011 which showed 44% of respondents use the range hood during dinner cooking and an additional 37% of respondents open windows during dinner cooking.

[215] To reduce complexity of the measure and since this relates to a small waste heat impact, instead of assuming actual existing unit HVAC efficiency and a mid-life adjustment to account for future replacement efficiency, the code minimum baseline should be applied. Starting from federal baseline of SEER2 13.4 central AC unit, converted to 11.4 EER2 using algorithm $(-0.02 * SEER^2) + (1.12 * SEER)$ (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = EER2 * 0.85/3.412 = 2.8COP.

[216] Heating penalty of 34.8% of appliance savings, estimated using average result from BEOPT simulation modeling comparing two different home configurations and two locations. Ratio compares the changes in home HVAC loads to changes in appliance energy consumption.

= actual. If not available use:[217]

System Type	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF/3.412)*0.85
Heat Pump	7.5	1.87
Resistance (Baseboard or Electric Furnace)	N/A	1.00
Unknown electric[218]	N/A	1.30

ηHeat = Efficiency of heating system

= 0.70 [219]

Non-fuel switch example, a residential induction cooktop will replace an electric resistance cooktop. The annual energy consumption of the induction cooktop has not been measured. The electric savings are calculated below:

ΔkWh = $CooktopIAEC_{base}$ - $CooktopIAEC_{ee}$

$CooktopIAEC_{ee}$ = 184.2 kWh/yr

$CooktopAEC_{base}$ = 236.9 kWh/yr

ΔkWh = 236.9 – 184.2

= 52.7 kWh/yr

[217] To reduce complexity of the measure and since this relates to a small waste heat impact, instead of assuming actual existing unit HVAC efficiency and a mid-life adjustment to account for future replacement efficiency, the code minimum baseline should be applied. Note efficiency includes duct losses. Defaults provided assume 15% duct loss for heat pumps.

[218] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Program or evaluation data should be used to improve this assumption if available.

[219] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey) In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

Fuel switch example: a residential induction cooktop will replace a natural gas cooktop in a single family non-IQ home. The annual energy consumption of the induction cooktop has not been measured and the homes heating fuel and presence of central cooling is unknown. The savings for a measure supported by an electric utility are calculated below:

ΔSiteEnergySavings (MMBtu)	= [ΔCookingSavings] + [HVACImpacts]
ΔCookingSavings	= [GasConsumptionReplaced] – [ElectricConsumptionAdded]
	= [$CooktopAEC_{base}$ /10] – [$CooktopIAEC_{ee}$ * 3,412/1,000,000]
	= [19/10] – [184.2 * 3412/1000000]
	= 1.9 – 0.628
	=1.272 MMBtu
CoolingImpact	= ΔCookingSavings * %Cool * HCF_{COOL} * VentFactor / COP_{COOL}
	= 1.272 * 0.989 * 0.21 * 0.5 / 3.3
	= 0.04 MMBtu
ElecHeatImpact	= ΔCookingSavings * %ElecHeat * HCF_{HEAT} * VentFactor / COP_{HEAT}
	= 1.272 * 0.26 * 0.348 * 0.5 / 1.3
	= 0.044 MMBtu
FuelHeatImpact	= ΔCookingSavings * %GasHeat *HCF_{HEAT} * VentFactor / ηHeat
	= 1.272 * 0.74 * 0.348 * 0.5 / 0.7
	= 0.234 MMBtu
HVAC Impacts	= [CoolingImpact] – [ElecHeatImpact] – [FuelHeatImpact]
	= 0.04 – 0.044 – 0.234
	= -0.238 MMBtu
ΔSiteEnergySavings (MMBtu)	= 1.272 + (- 0.238)
	= 1.034 MMBtu

ΔkWh = ΔSiteEnergySavings * 1,000,000 / 3,412
= 1.034 * 1000000/3412
= 303 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

For Non-Fuel Switching measures:

$$\Delta kW = (CooktopAEC_{base} - CooktopIAEC_{ee})/Hours * WHFd * CF$$

For Fuel Switching measures:

$$\Delta kW = ((AEC_{baseElectric} - IAEC_{ee} + [CoolingImpact] – [ElecHeatImpact]) * 1,000,000/3,412) /Hours * WHFd * CF$$

Where:

Hours = Annual operating hours[220]

= 239 hours

WHFd = Waste heat factor for demand to account for cooling savings from efficient appliance.

= 1.11[221]

CF = Summer Peak Coincidence Factor

= 29% [222]

All other variables as presented above

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below) adjusted for utility line losses (at-the-busbar savings), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, this will not match the output of the calculation/allocation methodology presented in the "Electric Energy Savings" and "Fossil Fuel Savings" sections above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = ([Gas Cooking Consumption Replaced] – [FuelHeatImpact]) * 10

= ($AEC_{baseGas}$ – FuelHeatImpact) * 10

ΔkWh = ([Electric Cooking Replaced] - [Electric Cooking Consumption Added] + [CoolingImpact] – [ElecHeatImpact]) * 1,000,000/3,412

= ($AEC_{baseElectric}$ - $IAEC_{ee}$ + [CoolingImpact] – [ElecHeatImpact]) * 1,000,000/3,412

MEASURE CODE: RS-MSC-INDC-V04-260101

REVIEW DEADLINE: 1/1/2029

[220] Assuming 1 hours per cycle and 239 cycles per year therefore 239 operating hours per year. 239 cycles per year is based on a 2016 CASE study for PG&E modeling Plug Loads.

[221] The value is estimated at 1.11 (calculated as 1 + (0.66 * 0.466 / 2.8)). See footnote relating to WHFe for details. Note the 46.6% factor represents the average Residential cooling coincidence factor calculated by dividing average load during the peak hours divided by the maximum cooling load.

[222] Calculated from ResStock, 15 minute interval data by end use for Illinois, as provided by NREL.

5.1.15 Residential Bolt-On Smart Dryer Sensor

DESCRIPTION

This measure relates to the installation of a bolt-on smart wifi enabled dryer sensor with cloud data storage access on a residential gas-fired or electric dryer. A smart dryer sensor is an add-on device, which turns any residential dryer into a smart dryer. The device consists of

1) a sensor that detects temperature and humidity in the dryer
2) a connected hub with a built-in auto shut-off mechanism

The sensor monitors the temperature and humidity inside the clothes dryer to determine when a load is dry. When the humidity levels in the dryer fall below a pre-set cut-off at steady state, the device determines that a load is dry. The sensor then notifies the connected auto shut-off mechanism, cutting off power to the dryer and turning it off.

Residential clothes dryers have not changed significantly in their operation for many years. They typically offer either a time-dry setting (which uses a set timer) or an auto-dry setting (which uses a built-in moisture sensor to determine when the clothes are dry). Most built-in manufacturer moisture sensors do not work well, and users tend to predominantly use the time-dry setting. This measure does not apply to dryers with coin operated mechanical timers, laundromat facilities or commercial clothes dryers. This measure was developed to be applicable to the following program types: TOS, RF, NC, DI and KITS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Natural gas-fired or electric resistance dryers with a residential bolt-on smart dryer sensor installed.

DEFINITION OF BASELINE EQUIPMENT

The base case equipment is a conventional gas-fired or electric resistance residential dryer without a bolt-on smart dryer sensor installed. The dryer may have a built-in moisture sensor installed. The gas-fired dryer has a natural gas fuel-fired burner element and an electric powered drum motor.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be same as that of the clothes dryer, which is 16 years.[223]

DEEMED MEASURE COST

The deemed measure cost is $60 for a new residential bolt-on smart dryer sensor when installed on a gas-fired dryer. This applies to a non-intrusive bolt-on sensor installed with a magnetically attachable sensor inside the drum and a wirelessly connected plug with an auto shut-off.[224]

When attached to an electric dryer the deemed measure cost is $150[225].

Actual costs should be used when available or if the smart sensor setup is different from the above.

LOADSHAPE

Loadshape R17 - Residential Electric Dryer

COINCIDENCE FACTOR

N/A

[223] Based on DOE Rulemaking Technical Support Document, LCC Chapter, 2011, as recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.
[224] Based on Nicor Gas ETP field demonstration of Residential IoT Smart Dryer Sensors.
[225] Based on current market cost for TickleStar DryerSaver Model #TS2201.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

For all dryers, please use the following equation for calculating energy savings, related to the motor:

$\Delta kWh_{motor} = N_{cycles} * (Motor_{runtimesavings}) * Motor_{kW}$

Where:

N_{cycles} = Number of dryer cycles per year. Use actual data if available. If unknown:

= 259 cycles per year.[226]

$Motor_{runtimesavings}$ = Runtime savings for dryer drum motor

= 0.39 hrs/load[227]

$Motor_{kW}$ = Rated electric power draw of drum motor. Use actual nameplate data. If unknown,

= 0.25 kW.[228]

For electric resistance dryers, please use the following equation for calculating energy savings, related to the heating element:

$\Delta kWh_{heating} = N_{cycles} * RunTimeSavings * Dryer\ Draw\ Rate / 1{,}000$

Where:

RunTimeSavings = Runtime savings for dryer heating element

= 0.08 hrs/load[229]

Dryer Draw Rate = Draw of electric resistance dryer heaters.

= Use actual nameplate data if available. If unknown, 5,250 Watts.[230]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$\Delta kW = \Delta kWh / Hours * CF$

Where:

ΔkWh = Electric Energy Savings as calculated above

For gas-fired dryers = ΔkWh_{motor}

[226] Loads per week was estimated by taking the weighted average of the number of loads per week (midpoint used where loads per week is a range and the weights are the share of respondents falling into each number of loads per week response bin). This estimate was scaled to an IL-specific value by applying a ratio developed using the 2009 state specific values for the states in the East North Central portion of the Midwest Region. Reduced by 6% to maintain prior ratio of dryer to clothes washer loads of 94%.

[227] Average data based on Nicor Gas ETP field demonstration of Residential IoT Smart Dryer Sensors. Please see Analysis file.

[228] Average Residential dryer drum motors, which typically range between 200 W and 300 W. Please see ENERGY STAR Scoping Reporting for Residential Clothes Dryers file, Table 2, page 3.

[229] Average data based on Nicor Gas ETP field demonstration of Residential IoT Smart Dryer Sensors. Based on natural-gas fired dryer data, and assuming similar savings will be seen for electric dryer.

[230] Average Residential electric resistance heaters typically draw about 5,000 - 5,500 watts. Please see ENERGY STAR Scoping Reporting for Residential Clothes Dryers file, Table 2, page 3.

For electric dryers = $\Delta kWh_{motor} + \Delta kWh_{heating}$

Hours = Annual run hours of clothes dryer.

= Use actual data, if available. If unknown, use 259 hours per year.[231]

CF = Summer Peak Coincidence Factor for measure

= 3.8%[232]

FOSSIL FUEL SAVINGS

For natural gas-fired dryers, please use the following equation for calculating energy savings:

$\Delta Therm = N_{cycles} * Therm_{convert} * RunTimeSavings * Dryer\ Firing\ Rate$

Where:

N_{cycles} = Number of dryer cycles per year.

= Use actual data, if available. If unknown, use 259 cycles per year.[233]

$Therm_{convert}$ = Conversion factor from Btu to Therm

= 0.00001

RunTimeSavings = Runtime savings for gas dryer burner element

= 0.08 hrs/load[234]

Dryer Firing Rate = Firing rate of the natural gas-fired dryer burner.

= Use actual nameplate data, if available. If unknown, use 22,500 Btu/hr.[235]

For example, A single-family home in Chicago is retrofitting a residential bolt-on smart dryer sensor on a 22,500 Btu/hr natural gas-fired dryer with 400 loads annually. The annual savings for the installation would be:

Electric Energy Savings

= 400 x 0.39 x 0.25

= 39 kWh

Natural Gas Savings

= 400 x 0.00001 x 0.08 x 22,500

= 7.2 therms

[231] ENERGY STAR qualified dryers have a maximum test cycle time of 80 minutes. Assume one hour per dryer cycle from existing TRM measure 5.1.10.

[232] Based on coincidence factor of 3.8% for clothes washers from existing Illinois TRM measure 5.1.10.

[233]Loads per week was estimated by taking the weighted average of the number of loads per week (midpoint used where loads per week is a range and the weights are the share of respondents falling into each number of loads per week response bin). This estimate was scaled to an IL-specific value by applying a ratio developed using the 2009 state specific values for the states in the East North Central portion of the Midwest Region. Reduced by 6% to maintain prior ratio of dryer to clothes washer loads of 94%..

[234] Average data based on Nicor Gas ETP field demonstration of Residential IoT Smart Dryer Sensors. See Analysis file for details.

[235] Residential dryer burners typically range between 20,000 Btu/hr – 25,000 Btu/hr. Please see ENERGY STAR Scoping Reporting for Residential Clothes Dryers file, Table 2, page 3.

5.1.16 Electric Lawn and Garden Equipment

DESCRIPTION

This measure identifies the claimed savings associated with residential lawn equipment electrification. This measure was developed to be applicable to the following program types: TOS.

Time of Sale (TOS):

- The use of an all-electric equipment in place of an equipment with a spark-ignition gasoline-powered engine.
- Note that the baseline in this case is an equivalent replacement system to that which exists currently in the home.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is an all-electric lawn or garden equipment sized to be equivalent to the baseline equipment.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is new gasoline-powered lawn or garden equipment.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life varies based on the equipment type (displayed in the table below).

Equipment Type	Measure Life (years)[236]
Riding Lawn Mower	9
Push Lawn Mower	9
Leaf Blower	5
Trimmer	5
Chainsaw	7

DEEMED MEASURE COST

For Time of Sale (TOS) the incremental cost should be used. Actual costs can also be used although care should be taken as costs can vary significantly. Defaults are provided below.

Equipment Type	Incremental Cost[237]
Riding Lawn Mower	$3,890
Push Lawn Mower	$419
Leaf Blower	$206
Trimmer	$272
Chainsaw	$384

LOADSHAPE

Loadshape R08 – Residential Cooling[238]

[236] CARB (2022). CCI Emission Factor Database, "Fuel-Specific GHG" worksheet, available at cci_emissionfactordatabase_2022-11-30.xlsx (live.com).
[237] Vermont Act 56 Tier III Technical Advisory Group 2021 ANNUAL REPORT
[238] Residential cooling loadshape is used as an estimate of likely usage pattern for electric lawn equipment. This methodology is used in other jurisdictions offering electric lawn care equipment savings.

COINCIDENCE FACTOR

The summer Peak Coincidence Factor is assumed to be 30%.[239]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS

Fuel switch measure (baseline is gas equipment):

Fuel switch / electrification measures must produce positive total energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

ΔSiteEnergySavings (MMBtu) = [GasConsumptionReplaced] – [ElectricConsumptionAdded]

= [$Fuel_{baseline}$ * 120,238/1,000,000] – [$Fuel_{baseline}$ * $ED_{gasoline}$ / ($ED_{electricity}$ * $EER_{G\rightarrow E}$) * 3,412/1,000,000]

$Fuel_{baseline}$ = ($BSFC_{baseline}$ * $hp_{baseline}$ * $LF_{baseline}$ * Hours) / (Fuel $Density_{gasoline}$)

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:

$BSFC_{baseline}$ = Brake Specific Fuel (Gasoline) Consumption Factor (lbs/hp-hr)

= If unknown, use default values in the table below

$hp_{baseline}$ = Horsepower of the lawn equipment

= If unknown, use default values in the table below

$LF_{baseline}$ = The load factor is the average operational level of an engine as a fraction or percentage of the engine manufacturer's maximum rated horsepower. Load factor is difficult to characterize since it is a strong function of the equipment use and operation. Load factors for various equipment types are presented in the table below.

Hours = Annual operating hours of the lawn or garden equipment.

[239] Consistent with coincidence factors found in: RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008.

= Values for various equipment types are presented in the table below.

$\text{Fuel Density}_{\text{gasoline}}$ = Gasoline fuel density (assume 6.15 lbs/gal)[240]

$\text{ED}_{\text{gasoline}}$ = Energy density of gasoline (assume 115.83 MJ/gal)[241]

$\text{ED}_{\text{electricity}}$ = Energy density of electricity = 3.6 MJ/kWh

$EER_{G \to E}$ = Energy Economy Ratio = 3.4 (for switching from gasoline to electricity)[242]

120,238 = Btu content in one gallon of finished gasoline[243]

1,000,000 = Btu to MMBtu conversion

Equipment Type	$\text{BSFC}_{\text{baseline}}$ (lbs/hp-hr)[244]	$\text{hp}_{\text{baseline}}$[234]	$\text{LF}_{\text{baseline}}$[234]	Hours (hrs/year)[234]	ΔkWh	ΔMMBtu	Site Energy Savings (MMBtu)
Riding Lawn Mower	0.779	21.4	38%	36	-350.9	4.5	3.3
Push Lawn Mower	0.830	3.9	33%	25	-41.1	0.5	0.4
Leaf Blower	0.874	2.0	94%	10	-25.3	0.3	0.2
Trimmer	0.922	1.2	91%	9	-13.9	0.2	0.1
Chainsaw	0.770	1.9	70%	13	-20.5	0.3	0.2

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta\text{kW} = -1 * \text{kW}_{\text{battery draw}} * \text{CF}$$

Where:

$\text{kW}_{\text{battery draw}}$ = The electric draw by the battery during charging. This varies based on the battery and charger specifications. If unknown use values in the table below.

Equipment Type	$\text{kW}_{\text{battery draw}}$
Riding Lawn Mower	0.57[245]
Push Lawn Mower	0.42[246]
Leaf Blower	0.20[236]
Trimmer	0.00[236]
Chainsaw	0.00[236]

CF = Summer Peak Coincidence Factor

= 30%[247]

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below) adjusted for utility line losses (at-the-busbar savings), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, this will not match the output of the calculation/allocation methodology presented in the "Electric Energy Savings" and "Fossil Fuel Savings" sections above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = [Gas Consumption Replaced]

$= (BSFC_{baseline} * hp_{baseline} * LF_{baseline} * Hours) / (Fuel\ Density_{gasoline}) * 120{,}238/100{,}000$

ΔkWh = [Electric Consumption Added]

$= (BSFC_{baseline} * hp_{baseline} * LF_{baseline} * Hours) / (Fuel\ Density_{gasoline}) * ED_{gasoline} / (ED_{electricity} * EER_{G \rightarrow E})$

MEASURE CODE: RS-APL-ELGE-V01-240101

REVIEW DEADLINE: 1/1/2028

5.1.17 ENERGY STAR All-in-One Clothes Washer-Dryer

DESCRIPTION

This measure relates to the installation of a residential combination all-in-one clothes washer-dryer meeting the ENERGY STAR[248] criteria. ENERGY STAR qualified combination all-in-one clothes washer-dryers save energy through a combination of more efficient drying and reduced runtime of the drying cycle. More efficient washing and drying is achieved through heat pump technology, modifying operating conditions such as air flow and/or heat input rate, improving air circulation through better drum design, and improving efficiency of motors. ENERGY STAR provides criteria for electric clothes washer-dryers with heat pump technology.

This measure was developed to be applicable to the following program types: Time of Sale, New Construction, Retrofit. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

All-in-one clothes washer-dryer must meet the ENERGY STAR or ENERGY STAR Most Efficient criteria, as required by the program. Units utilizing the Heat Pump designation must meet the same ENERGY STAR criteria and be classified as Heat Pump units.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition for a washing cycle is a clothes washer meeting the minimum federal baseline as of January 2018[249].

Efficiency Level	Top Loading ≥1.6 Cu ft	Front Loading ≥1.6 Cu ft
Federal Standard	≥1.57 IMEF, ≤6.5 IWF	≥1.84 IMEF, ≤4.7 IWF

The baseline condition used for a washing cycle for this measure is a weighted average of 1.7 IMEF.[250]

The baseline condition for a drying cycle is a clothes dryer meeting the minimum federal requirements for units manufactured on or after January 1, 2015.

Efficiency Level	Front Loading ≥4.5 Cu ft
Federal Standard for Clothes Dryer	3.11[251] CEF for Vented Electric, 2.84[252] CEF for Vented Gas

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 14 years[253].

DEEMED MEASURE COST

The average cost of the ENERGY STAR combination all-in-one clothes washer-dryer $2,331 with no additional

[248] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[249]DOE Energy Conservation Standards for Clothes Washers, Appliance and Equipment Standard, 10 CFR Part 430.32(g)
[250] Weighted average IMEF of Federal Standard rating for Front Loading and Top Loading units. Weighting is based upon the relative top v front loading percentage of available non-ENERGY STAR product in the CEC database (products accessed on 04/21/2022).
[251] ENERGY STAR Draft 2 Version 1.0 Clothes Dryers Data and Analysis
[252] Federal standards report CEF for gas clothes dryers in terms of lbs/kWh. To determine gas savings, this number is later converted to therms.
[253] Lifetime of 14 years per Residential Clothes Washers Life-Cycle Cost Analysis Spreadsheet posted by the Energy Efficiency and Renewable Energy Office on Sep 23, 2021.

installation cost for a total measure cost of $2,331.[254]

For a non-IQ participant, the incremental cost is assumed to be $1,328.[255]

For an IQ participant, the incremental cost is assumed to be $1,224.[256]

LOADSHAPE

Loadshape R17 - Residential Electric Dryer

COINCIDENCE FACTOR

The coincidence factor for this measure is 3.8%.[257]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Non Fuel Switch Measures[258]

$$\Delta kWh_{total}[259] = \Delta kWh_{clothes\ washer} + \Delta kWh_{dryer}$$

$$\Delta kWh_{clothes\ washer} = [Capacity * IQAdj_{CW}/IMEFbase * Ncycles * (\%CWbase + (\%DHWbase * \%Electric_DHW))] - [Capacity * 1/IMEFeff * Ncycles * (\%CWeff + (\%DHWeff * \%Electric_DHW))]$$

$$\Delta Therms = [Capacity * IQAdj_{CW}/IMEFbase * Ncycles * (\%DHWbase * \%Fossil_DHW * R_eff)] - [Capacity * 1/IMEFeff * Ncycles * (\%DHWeff * \%Fossil_DHW *R_eff)] * ThermConvert$$

$$\Delta kWh_{dryer} = ((Load/CEFbase* IQAdj_D) – Load/CEFeff) * Ncycles * \%Electric$$

Fuel Switch/Electrification Measures

Total Site Energy Savings (MMBTUs) = Site Energy Savings $(MMBTUs)_{clothes\ washer}$ + Site Energy Savings $(MMBTUs)_{dryer}$

Break out savings calculated for the washing cycle for a baseline clothes washer with gas DHW replaced with an all-in-one clothes washer-dryer with electric DHW

[254] The cost of buying a new market available all-in-one clothes washer-dryer with HP technology from Home Depot have been averaged for three different manufacturers. These products are ENERGY STAR certified. See "Incremental Cost R&D.xls" for information.

[255] The baseline cost is assumed to be the cost of a standard efficiency clothes washer in addition to the cost of a standard efficiency clothes dryer. A standard clothes washer cost ($763.98) is based on analysis of cost data provided in the Retail Price Data from DOE Analytical Tool (Lifecycle Cost and Payback Period Analysis) for Negotiated Standards, 2017, and weighted by a market share of 49.4% Top-Loading to 50.6% Front-Loading machines. The cost of a standard dryer ($564) is from "ACEEE Clothes Dryers.pdf."

[256] IQ Incremental costs factor in the assumption that a secondhand unit costs on average 50% of a new baseline unit, and that 1/3 of IQ participants would have purchased a unit on the secondhand market. See "IQ Appliance Calculations.xls" for information.

[257] Calculated from Itron eShapes, 8760 hourly data by end use for Missouri, as provided by Ameren.

[258] Non-Fuel Switch Measures apply in cases where inefficient electric equipment is being replaced with efficient electric equipment. Assume DHW fuel remains consistent between baseline and efficient scenario. Clothes washer unit savings are always non-fuel switch; however thermal savings can exist in applications with gas DHW.

[259] The energy savings algorithm from the clothes dryer and clothes washer has been calculated individually to create the final algorithm for the Energy Star Combination All-in-One Clothes Washer-Dryer. The dryer section from the clothes washer algorithm has been excluded. See "Energy Star Combination All-in-One Clothes Washer-Dryer Calculations.xls" for information.

$SiteEnergySavings(MMBTUs)_{clothes\ washer} = [NonFuelSwitchSavings_{clothes\ washer}]$

$NonFuelSwitchSavings_{clothes\ washer} = [(ElectricConsumption_{Baseline\ clothes\ washer} + GasConsumption_{Baseline\ clothes\ washer}) – (EfficientConsumption_{efficient\ clothes\ washer} + GasConsumption_{efficient\ clothes\ washer})]$

$ElectricConsumption^{260}_{Baseline\ clothes\ washer} = [Capacity * IQAdj_{CW}/IMEFbase * Ncycles * (\%CWbase + (\%DHWbase * \%Electric_DHW)) * MMBtu_convert]$

$GasConsumption_{Baseline\ clothes\ washer} = [Capacity * IQAdj_{CW}/IMEFbase * Ncycles * (\%DHWbase * \%Fossil_DHW * R_eff) * MMBtu_convert]$

$ElectricConsumption_{efficient\ clothes\ washer} = [Capacity * 1/IMEFeff * Ncycles * (\%CWeff + (\%DHWeff * \%Electric_DHW) * MMBtu_convert]$

$GasConsumption_{efficient\ clothes\ washer} = [Capacity * IQAdj_{CW}/IMEFeff * Ncycles * (\%DHWeff * \%Fossil_DHW * R_eff) * MMBtu_convert]$

Break out savings calculated for the drying cycle for a basline gas dryer replaced with an all-in-one clothes washer-dryer.

$Site\ Energy\ Savings\ (MMBTUs)_{dryer}$[259] $= [FuelSwitchSavings_{dryer}] + [NonFuelSwitchSavings_{dryer}]$

$FuelSwitchSavings_{dryer} = [Load/CEFbase_{Gas} * IQAdj_{D} * Ncycles * MMBtu_convert * \%Gas_{Gas}] - [Load/CEFeff_{Elec} * Ncycles * MMBtu_convert * \%Gas_{Gas}]$

$NonFuelSwitchSavings_{dryer} = [Load/CEFbase_{Gas} * IQAdj_{D} * Ncycles* MMBtu_convert * \%Electric_{Gas}] - [Load/CEFeff_{Elec} * Ncycles * MMBtu_convert * \%Electric_{Gas}]$

If Total Site Energy Savings (MMBTUs) calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Gas utility only	N/A	SiteEnergySavings * 10

Where:

Capacity = Unit capacity (cubic feet)

= Actual. If capacity is unknown assume 4.9 cubic feet[261]

IMEFbase = Integrated Modified Energy Factor of baseline clothes washer unit

= 1.71[262]

$IQAdj_{CW}$ =Baseline consumption adjustment for IQ program participants to account for a

[260] Electric consumption that accounts for the fact that some of the consumption on gas DHW Clothes Washer comes from electricity (motors, controls, etc).

[261] Average of ENERGY STAR & ENERGY STAR MOST EFFICIENT Residential Combination All-in-One Washer-Dryer. April 2024. https://www.energystar.gov/productfinder/product/certified-clothes-washers.

[262] Weighted average IMEF of Federal Standard rating for Front Loading and Top Loading units. Weighting is based upon the relative top v front loading percentage of available non-ENERGY STAR product in the CEC database (products accessed on 04/21/2022).

portion of participants who would have utilized the secondary market.[263]

= 1.02 if IQ, 1.0 if non-IQ

IMEFeff = Integrated Modified Energy Factor of Efficient Combination All-in-One Washer-Dryer unit

= Actual. If unknown assume average values provided below.

Efficiency Class	IMEFeff[264]
ENERGY STAR	2.76
ENERGY STAR Most Efficient	2.92

Ncycles = Number of cycles per year

= 276[265]

%CW = Percentage of total energy consumption for Clothes Washer operation (different for baseline and efficient unit – see table below)

%DHW = Percentage of total energy consumption used for water heating (different for baseline and efficient unit – see table below)

Product Class	Percentage of Total Energy Consumption of Clothes Washer[266]	
	%CW	%DHW
Baseline	6.7%	15.8%
Efficient	6.6%	13.0%

%Electric_DHW = Percentage of DHW savings assumed to be electric

= 100 % for Electric

= 0 % for Fossil Fuel

= If unknown[267], use the following table:

[263] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (9 years). The baseline consumption of a unit meeting the pre 03/2015 Federal Standard was increased by an estimate of 0.4% * 9 years (based on review of the refrigerator/freezer regression algorithm used in the 5.1.8 Refrigerator and Freezer Recycling measure) to account for degradation of performance over time. For 2025 on, the post 03/2015 Federal Standard is utilized. This second hand consumption was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.

[264] The energy measurements are performed at an ISO/IEC accredited lab as specified in the application process for the ENERGY STAR & ENERGY STAR Most Efficient. Approved products on the ENERGY STAR Qualified Products List 2024-04-23 have IMEF, IWF values listed for clothes washer and CEF values for clothes dryer.

[265] Loads per week was estimated by taking the weighted average of the number of loads per week (midpoint used where loads per week is a range and the weights are the share of respondents falling into each number of loads per week response bin). This estimate was scaled to an IL-specific value by applying a ratio developed using the 2009 state specific values for the states in the East North Central portion of the Midwest Region. This value was then scaled to apply to a consistent amount of laundry washed over time.

[266] The percentage of total energy consumption that is used for the machine, heating the hot water or by the dryer is different depending on the efficiency of the unit. Values are based on a weighted average of top loading and front loading units based on data from the 2017 DOE Life-Cycle Cost and Payback Period Excel-based analytical tool. See "IL TRM_CW Analysis_082024.xlsx" for the calculation.

[267] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

Product Class	Location				
Utility	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	19.7%	30.6%	63.3%	67.3%	31.4%
ComED	14.0%	21.5%	43.0%	48.4%	32.9%
People's Gas	2.1%	2.0%	1.7%	2.4%	2.2%
Northshore Gas	1.5%	1.8%	10.0%	2.4%	2.4%
Nicor Gas	7.6%	9.9%	14.4%	22.6%	10.0%
All DUs[268]					29%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Load = The average total weight (lbs) of clothes per drying cycle. If unit size is unknown, assume standard.

Unit Size	Load (lbs)[269]
Standard	8.45

CEFbase = Combined energy factor (CEF) (lbs/kWh) of the baseline unit is based on existing federal standards energy factor as performed in the ENERGY STAR analysis[251]. If product class unknown, assume electric, standard.

Product Class	CEFbase (lbs/kWh)
Vented Electric, Standard (≥ 4.4 ft3)	3.11
Vented Gas	2.84[252]

$IQAdj_D$ = Baseline consumption adjustment for IQ program participants to account for a portion of participants who would have utilized the secondary market.[270]
= 1.033 if IQ, 1.0 if non-IQ

CEFeff = CEF (lbs/kWh) of ENERGY STAR or ENERGY STAR Most Efficient requirements Combination All-in-One Washer-Dryer.
= Actual. If unknown assume values provided below.

Efficiency Class	CEFeff (lbs/kWh)[264]
ENERGY STAR	4.97
ENERGY STAR Most Efficient	6.9

[268] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.
[269] Based on ENERGY STAR test procedures
[270] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (11 years). The current Federal Standard became effective in 2015 so the previous standard is used to estimate base consumption for a second hand unit, and further increased by an estimate of 0.4% * 11 years (based on review of the refrigerator/freezer regression algorithm used in the 5.1.8 Refrigerator and Freezer Recycling measure) to account for degradation of performance over time. This second hand consumption was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.

%Electric = The percent of overall savings coming from electricity.

= 100% for electric dryers, 16% for gas dryers[271].

%Fossil_DHW = Percentage of DHW savings assumed to be Fossil Fuel

= 100 % for Fossil fuel

= 0 % for Electric

= If unknown[272], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%
ComED	86.0%	78.5%	57.0%	51.6%	67.1%
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs[273]					71%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

R_eff = Recovery efficiency factor

=1.26[274]

MMBtu_convert = Conversion factor from kWh to MMBtu.

= 0.003412

%Gas = Percent of overall savings coming from gas.
= 0% for electric dryers and 84% for gas dryers[275].

[271] %Electric accounts for the fact that some of the savings on gas dryers comes from electricity (motors, controls, etc). 16% was determined using a ratio of the electric to total savings from gas dryers given by ENERGY STAR Draft 2 Version 1.0 Clothes Dryers Data and Analysis.

[272] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[273] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

[274] To account for the different efficiency of electric and Natural Gas hot water heaters (gas water heater: recovery efficiencies ranging from 0.74 to 0.85 (0.78 used), and electric water heater with 0.98 recovery efficiency (see ENERGY STAR Waste Water Recovery Guidelines). Therefore a factor of 0.98/0.78 (1.26) is applied.

[275] %Gas accounts for the fact that some of the savings on gas dryers comes from electricity (motors, controls, etc). 84% was determined using a ratio of the gas to total savings from gas dryers given by ENERGY STAR Draft 2 Version 1.0 Clothes Dryers Data and Analysis.

For example:

Non Fuel Switch example, for a non- IQ Time of Sale, standard, ventless, ENERGY STAR All-in-One Clothes Washer-Dryer:

$$\Delta kWh_{total} = \Delta kWh_{clothes\ washer} + \Delta kWh_{dryer}$$

$$\Delta kWh_{clothes\ washer} = [Capacity * 1/IMEFbase * Ncycles * (\%CWbase + (\%DHWbase * \%Electric_DHW))] - [Capacity * 1/IMEFeff * Ncycles * (\%CWeff + (\%DHWeff * \%Electric_DHW))]$$

$$\Delta kWh_{dryer} = ((Load/CEFbase * IQAdj) – Load/CEFeff) * Ncycles * \%Electric$$

ENERGY STAR

$\Delta kWh_{clothes\ washer}$ = (4.9 * 1/1.71 * 276 * (6.7% + (15.8% * 100%))) – (4.9 * 1/2.76 * 276 *(6.6% + (13% * 100%)))

= 81.9 kWh

ΔkWh_{dryer} = ((8.45/3.11*1) – 8.45/4.97) * 276 *100%

= 280.6 kWh

ΔkWh_{Total} = 280.6 + 81.9

= 363 kWh

ENERGY STAR Most Efficient/CEE Tier 2

$\Delta kWh_{clothes\ washer}$ = (4.9 * 1/1.71 * 276 * (6.7% + (15.8% * 100%))) – (4.9 * 1/2.92 * 276 * (6.6% + (13% * 100%)))

= 87.2 kWh

ΔkWh_{dryer} = ((8.45/3.11*1) – 8.45/6.9) * 276 *100%

= 411.9 kWh

ΔkWh_{Total} = 411.9 + 87.2

= 499 kWh

Fuel switch example, for a Time of Sale, an ENERGY STAR All-in-One Clothes Washer-Dryer in place of a clothes washer with gas DHW and vented gas dryer:

$$Total\ SiteEnergySavings\ (MMBTUs) = SiteEnergySavings\ (MMBTUs)_{clothes\ washer} + SiteEnergySavings\ (MMBTUs)_{dryer}$$

$$SiteEnergySavings\ (MMBTUs)_{clothes\ washer} = [(ElectricConsumption_{Baseline\ clothes\ washer} + GasConsumption_{Baseline\ clothes\ washer}) – EfficientConsumption_{efficient\ clothes\ washer}]$$

$$ElectricConsumption_{clothes\ washer} = [(Capacity * 1/IMEFbase * Ncycles * ((\%CWbase + \%Electric_DHW) *MMBtu_convert]$$

= (4.9 * 1/1.71 * 276 * (6.7% + (15.8% * 0%)) * 0.003412)

= 0.18 MMBTU

$GasConsumption_{Baseline\ clothes\ washer}$ = [Capacity * 1/IMEFbase * Ncycles * (%DHWbase * %Fossil_DHW * R_eff) * MMBtu_convert]

= (4.9 * 1/1.71 * 276 * (15.8% * 1 * 1.26))* 0.003412)

= 0.54 MMBTU

$EfficientConsumption_{efficient\ clothes\ washer}$ = [Capacity * 1/IMEFbase * Ncycles * (%CWeff + (%DHWeff * %Electric_DHW) * MMBtu_convert]

= (4.9 * 1/2.8 * 276 * (6.6% + (13% * 100%)) * 0.003412)

= 0.32 MMBTU

$SiteEnergySavings\ (MMBTUs)_{clothes\ washer}$

= (0.18 + 0.54) – 0.32

= 0.40 MMBTU

$SiteEnergySavings\ (MMBTUs)_{dryer}$ = [$FuelSwitchSavings_{dryer}$] + [$NonFuelSwitchSavings_{dryer}$]

$FuelSwitchSavings_{dryer}$ = [$Load/CEFbase_{Gas}$ * IQAdj * Ncycles * MMBtu_convert * $\%Gas_{Gas}$] - [$Load/CEFeff_{Elec}$ * Ncycles * MMBtu_convert * $\%Gas_{Gas}$]

= (8.45/2.84 * 1 * 276 * 0.003412 * 84%) - (8.45/4.97 * 276 * 0.003412 * 84%)

= 1.01 MMBTU

$NonFuelSwitchSavings_{dryer}$ = [$Load/CEFbase_{Gas}$ * IQAdj * Ncycles * MMBtu_convert * $\%Electric_{Gas}$] - [$Load/CEFeff_{Elec}$ * Ncycles * MMBtu_convert * $\%Electric_{Gas}$]

= (8.45/2.84 * 1 * 276 * 0.003412 * 16%) - (8.45/4.97 * 276 * 0.003412 * 16%)

= 0.19 MMBTU

$SiteEnergySavings\ (MMBTUs)_{dryer}$

= 1.01 + 0.19

= 1.2 MMBTU

Total SiteEnergySavings (MMBTUs) = $SiteEnergySavings\ (MMBTUs)_{dryer}$ + $SiteEnergySavings\ (MMBTUs)_{clothes\ washer}$

= 0.40 + 1.2

= 1.6 MMBTU

If supported by an electric utility: ΔkWh = ΔTotal SiteEnergySavings(MMBTUs) * 1,000,000 / 3,412

= 1.6 * 1,000,000 / 3,412

= 469 kWh

If supported by a gas utility: ΔTherms = ΔTotal SiteEnergySavings(MMBTUs) * 10

= 1.6 * 10

= 16 Therms

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW_{Total}^{276} = ((\Delta kWh_{clothes\ washer} + \Delta kWh_{dryer})/ Hours) * CF$$

Where:

$\Delta kWh_{clothes\ washer}$ = Energy Savings as calculated above for clothes washer. Note: do not include the secondary savings in this calculation.

Hours = Assumed run hours of unit

= 630 hours[277]

ΔkWh_{dryer} = Energy Savings as calculated above for dryer. Note: do not include the secondary savings in this calculation.

CF = Summer Peak Coincidence Factor for measure.

= 0.038[257]

For example, for a Time of Sale, an ENERGYSTAR All-in-One Clothes Washer-Dryer

ΔkW = ((81.9 + 280.6) / 630) *0.038

= 0.02 kW

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above.

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

$$\Delta Water\ (gallons) = Capacity * ((IWFbase * IQAdj_{Water}) – IWFeff) * Ncycles$$

Where:

ΔWater (gallons) = Water saved, in gallons

IWFbase = Integrated Water Factor of baseline clothes washer

= 5.59[278]

$IQAdj_{Water}$ = Baseline water consumption adjustment for IQ program participants to account for a portion of participants who would have utilized the secondary

[276] The peak energy savings algorithm from the clothes dryer and clothes washer has been calculated individually to create the final algorithm for the Energy Star Combination All-in-One Clothes Washer-Dryer. The dryer section from the clothes washer algorithm has been excluded. See "Energy Star Combination All-in-One Clothes Washer-Dryer Calculations.xls" for information.
[277] Based on an average of reported cycle times for a normal load of models on the ENERGY STAR QPL.
[278] Weighted average IWF of Federal Standard rating for Front Loading and Top Loading units. Weighting is based upon the relative top v front loading percentage of available non-ENERGY STAR product in the CEC database (products accessed on 04/21/2022).

market.[279]

=1.02 if IQ, 1.0 if non-IQ

IWFeff = Water Factor of Efficient Combination All-in-One Washer-Dryer unit

= Actual. If unknown assume average values provided below

Using the default assumptions provided above, the prescriptive water savings for each efficiency level are presented below:

Effciency Class	IWFeff[264]	ΔWater [280] (gallons per year)
ENERGY STAR	3.1	3,367.5
ENERGY STAR Most Efficient	2.9	3,638.0

Other factors as defined above.

For example, for a non- IQ Time of Sale, standard, ventless, ENERGY STAR All-in-One Clothes Washer-Dryer:

ENERGY STAR

ΔWater = 4.9 * ((5.59 * 1) - 3.10) * 276

= 3,367.5 Gallons per year

ENERGY STAR Most Efficient/CEE Tier 2

ΔWater = 4.9 * ((5.59 *1) - 2.9) * 276

= 3,638.0 Gallons per year

Secondary kWh Savings for Clothes Washer Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) / 1{,}000{,}000 * E_{water\ total}$$

Where:

ΔWater (gallons) = Water saved, in gallons – as calculated below.

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

= 5010[281]

[279] It is assumed that a second-hand unit is on average 2/3 of a measure's EUL years old (9 years). The baseline consumption from the TRM in 2015 is assumed the second hand water consumption (note we do no assume a degradation over time for water consumption) was then weighted 1/3: 2/3 current new baseline to estimate a multiplier for IQ participants. See "IQ Appliance Calculations.xls" for information.

[280] Baseline clothes washer capacity is assumed to have 4.9 cu.ft. with 233 wash cycles for clothes washer.

[281] This factor includes 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information, please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

For example, for a non- IQ Time of Sale, standard, ventless, ENERGY STAR All-in-One Clothes Washer-Dryer:

ENERGY STAR

$$\Delta kWh_{water} = 3367.5/1{,}000{,}000 * 5{,}010$$

$$= 16.9 \text{ kWh}$$

ENERGY STAR Most Efficient/CEE Tier 2

$$\Delta kWh_{water} = 3638.0/1{,}000{,}000 * 5{,}010$$

$$= 18.2 \text{ kWh}$$

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below) adjusted for utility line losses (at-the-busbar savings), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, this will not match the output of the calculation/allocation methodology presented in the "Electric Energy Savings" and "Fossil Fuel Savings" sections above. Therefore, in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = [Clothes Washer with Gas DHW Consumption Replaced + Gas Dryer Consumption Replaced] – [All-in-One Clothes Washer-Dryer Consumption Added]

= [(Capacity * IQAdj/IMEFbase * Ncycles * (%DHWbase * %Fossil_DHW * R_eff)) + ((Load/$CEFbase_{Gas}$ * IQAdj) * Ncycles * Therm_convert * $\%Gas_{Gas}$) + ((Load/$CEFeff_{Elec}$ * IQAdj) * Ncycles * Therm_convert * $\%Gas_{Gas}$))] – [(Capacity * 1/IMEFeff * Ncycles * (%CWeff + (%DHWeff * %Electric_DHW) * Therm_convert) + (Load/CEFeff * Ncycles * $\%Gas_{gas}$* Therm_convert)]

ΔkWh = [Clothes Washer with Gas DHW Electric Consumption Replaced + Gas Dryer Electric Consumption Replaced] - [All-in-One Clothes Washer-Dryer Consumption Added]

= [((Load/$CEFbase_{Gas}$ * IQAdj) * Ncycles * $\%Electric_{Gas}$) + (Capacity * 1/IMEFbase * Ncycles * (%CWbase + (%DHWbase * $\%Electric_DHW_{base}$)] - [((Load/CEFeff * Ncycles * $\%Gas_{gas}$) + (Load/CEFeff * Ncycles * $\%Electric_{gas}$)) + (Capacity * 1/IMEFeff * Ncycles * (%CWeff + (%DHWeff * $\%Electric_DHW_{efficient}$)]

MEASURE CODE: RS-APL-ACWD-V02-260101

REVIEW DEADLINE: 1/1/2030

5.1.18 Residential Refrigerator Seal Replacement

DESCRIPTION

This measure characterizes the savings associated with installing new door gaskets on existing residential refrigerators where the existing gasket has been worn or damaged to the point where it no longer provides an effective seal. Tight fitting gaskets prevent infiltration of warm, moist air into the refrigerator, thereby reducing the cooling load. The reduction of moisture in the case also helps prevent frost on the evaporator coil. Frost buildup on the coil reduces the heat transfer effectiveness, reduces air passage, and increases energy use during the defrost cycle. Therefore, replacing defective door gaskets reduces compressor run time and improves the overall effectiveness of heat removal from the refrigerator.

This measure was developed to be applicable to the following program types: RF. This is an IQ-only measure.
If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is assumed to be a standard replacement gasket with the same profile and similar material composition as the original. The fit must be tight and seal properly upon installation with no visible gaps or tears.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be a worn refrigerator gasket with visible damage that allows air to enter the unit with the door closed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is 3 years[282]

DEEMED MEASURE COST

Measure costs are based on values from a door gasket measure maintained by the RTF (Regional Technical Forum)[283]. Original measure costs were adjusted for inflation from 2006 to 2024[284] and by typical door perimeter for reach-in cases (14.9 feet [285, 286]).

Annual Savings	Cost/foot
Refrigerator Section	$8.46
Freezer Section	$10.47

LOADSHAPE

Loadshape R05 - Residential Refrigerator

COINCIDENCE FACTOR

This measure has deemed kW savings therefore a coincidence factor does not apply.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = \text{UEC}_{Base} * \text{SF}$$

Where:

UEC_{BASE} = Annual Unit Energy Consumption of baseline refrigerator, from table below:

Product Category	UEC_{BASE} [287]
	IQ
1. Refrigerators and Refrigerator-freezers with manual defrost	363
2. Refrigerator-Freezer--partial automatic defrost	424
3. Refrigerator-Freezers--automatic defrost with top-mounted freezer without through-the-door ice service and all-refrigerators--automatic defrost	435
4. Refrigerator-Freezers--automatic defrost with side-mounted freezer without through-the-door ice service	512
5. Refrigerator-Freezers--automatic defrost with bottom-mounted freezer without through-the-door ice service	540
5A Refrigerator-freezer—automatic defrost with bottom-mounted freezer with through-the-door ice service	715
6. Refrigerator-Freezers--automatic defrost with top-mounted freezer with through-the-door ice service	601
7. Refrigerator-Freezers--automatic defrost with side-mounted freezer with through-the-door ice service	653

SF = Savings Factor, see table below

Door Seal Condition	Savings Factor[288]
Fair (some wear but no visible gaps)	20%
Poor (visible gaps in the seal)	30%

Deemed savings are provided below:

Product Category	ΔkWh Savings	
	Fair	Poor
1. Refrigerators and Refrigerator-freezers with manual defrost	72.6	108.9
2. Refrigerator-Freezer--partial automatic defrost	84.8	127.2
3. Refrigerator-Freezers--automatic defrost with top-mounted freezer without through-the-door ice service and all-refrigerators--automatic defrost	87.0	130.5

[287] Assumptions as provided in 5.1.6 ENERGY STAR, CEE Tier 2 or CEE Tier 3 Refrigerator.

[288] Based upon review of U.S. Department of Energy's Refrigerator and Freezer Energy Rating Online Search Tool, refrigerators with "fair" seals use 20% more energy and refrigerators with "poor" seals use 30% more energy. Accessed 8/21/2025. www.energy.gov/scep/wap/articles/refrigerator-and-freezer-energy-rating-online-search-tool.

Product Category	ΔkWh Savings	
	Fair	Poor
4. Refrigerator-Freezers--automatic defrost with side-mounted freezer without through-the-door ice service	102.4	153.6
5. Refrigerator-Freezers--automatic defrost with bottom-mounted freezer without through-the-door ice service	108.0	162.0
5A Refrigerator-freezer—automatic defrost with bottom-mounted freezer with through-the-door ice service	143.0	214.5
6. Refrigerator-Freezers--automatic defrost with top-mounted freezer with through-the-door ice service	120.2	180.3
7. Refrigerator-Freezers--automatic defrost with side-mounted freezer with through-the-door ice service	130.6	195.9

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta\text{kW} = \frac{\Delta kWh}{8766} * TAF * LSAF$$

Where:

8766 = Hours per year

TAF = Temperature Adjustment Factor

= 1.25[289]

LSAF = Load Shape Adjustment Factor

= 1.057[290]

Deemed savings are provided below:

Product Category	ΔkW Savings	
	Fair	Poor
1. Refrigerators and Refrigerator-freezers with manual defrost	0.0109	0.0164
2. Refrigerator-Freezer--partial automatic defrost	0.0128	0.0192
3. Refrigerator-Freezers--automatic defrost with top-mounted freezer without through-the-door ice service and all-refrigerators--automatic defrost	0.0131	0.0197
4. Refrigerator-Freezers--automatic defrost with side-mounted freezer without through-the-door ice service	0.0154	0.0232

[289] Average temperature adjustment factor (to account for temperature conditions during peak period as compared to year as a whole) based on Blasnik, Michael, "Measurement and Verification of Residential Refrigerator Energy Use, Final Report, 2003-2004 Metering Study", July 29, 2004 (p. 47). It assumes 90 °F average outside temperature during peak period, 71°F average temperature in kitchens and 65°F average temperature in basement, and uses assumption that 66% of homes in Illinois have central cooling (CAC saturation: "Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey).

[290] Daily load shape adjustment factor (average load in peak period /average daily load) also based on Blasnik, Michael, "Measurement and Verification of Residential Refrigerator Energy Use, Final Report, 2003-2004 Metering Study", July 29, 2004 (p. 48, using the average Existing Units Summer Profile for hours 13 through 17)

Product Category	ΔkW Savings	
	Fair	Poor
5. Refrigerator-Freezers--automatic defrost with bottom-mounted freezer without through-the-door ice service	0.0163	0.0244
5A Refrigerator-freezer—automatic defrost with bottom-mounted freezer with through-the-door ice service	0.0216	0.0323
6. Refrigerator-Freezers--automatic defrost with top-mounted freezer with through-the-door ice service	0.0181	0.0272
7. Refrigerator-Freezers--automatic defrost with side-mounted freezer with through-the-door ice service	0.0197	0.0295

5.2 Consumer Electronics End Use

5.2.1 Advanced Power Strip – Tier 1

DESCRIPTION

This measure relates to Advanced Power Strips – Tier 1 which are multi-plug surge protector power strips with the ability to automatically disconnect specific connected loads depending upon the power draw of a control load, also plugged into the strip. Power is disconnected from the switched (controlled) outlets when the control load power draw is reduced below a certain adjustable threshold, thus turning off the appliances plugged into the switched outlets. By disconnecting, the standby load of the controlled devices, the overall load of a centralized group of equipment (i.e. entertainment centers and home office) can be reduced. Uncontrolled outlets are also provided that are not affected by the control device and so are always providing power to any device plugged into it. This measure characterization provides savings for a 5-plug strip and a 7-plug strip.

This measure was developed to be applicable to the following program types: TOS, NC, DI, KITS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is the use of a 5 or 7-plug advanced power strip.

DEFINITION OF BASELINE EQUIPMENT

For time of sale or new construction applications, the assumed baseline is a standard power strip that does not control connected loads.

For direct install and kits, the baseline is the existing equipment utilized in the home.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of the advanced power strip is 7 years.[291]

DEEMED MEASURE COST

For time of sale or new construction the incremental cost of an advanced Tier 1 power strip over a standard power strip with surge protection is assumed to be $10.[292]

For direct install the actual full equipment and installation cost (including labor) and for kits the actual full equipment cost should be used.

Equipment cost if unknown[293]:

Baseline Cost	Efficient Cost	Incremental Equipment Cost
$20	$30	$10

LOADSHAPE

Loadshape R13 - Residential Standby Losses – Entertainment

Loadshape R14 - Residential Standby Losses - Home Office

[291] This is a consistent assumption with 5.2.2 Advanced Power Strip – Tier 2.
[292] Price survey performed by Illume Advising LLC for IL TRM workpaper, see "Current Surge Protector Costs and Comparison 7-2016" spreadsheet.
[293] Price survey performed by Illume Advising LLC for IL TRM workpaper, see "Current Surge Protector Costs and Comparison 7-2016" spreadsheet.

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 80%.[294]

Algorithm

CALCULATION OF SAVINGS ELECTRIC ENERGY SAVINGS

$$\Delta kWh = kWh * ISR$$

Where:

kWh = Assumed annual kWh savings per unit

= 56.5 kWh for 5-plug units or 103 kWh for 7-plug units[295]

ISR = In Service Rate, dependent on delivery mechanism

[294] Efficiency Vermont 2016 TRM coincidence factor for advanced power strip measure –in the absence of empirical evaluation data, this was based on assumptions of the typical run pattern for televisions and computers in homes.

5.2.2 Tier 2 Advanced Power Strips (APS) – Residential Audio Visual

DESCRIPTION

This measure relates to the installation of a Tier 2 Advanced Power Strip / surge protector for household audio visual environments (Tier 2 AV APS). Tier 2 AV APS are multi-plug power strips that remove power from audio visual equipment through intelligent control and monitoring strategies.

By utilizing advanced control strategies such as a countdown timer, external sensors (e.g. of infra-red remote usage and/or occupancy sensors, true RMS (Root Mean Square) power sensing; both active power loads and standby power loads of controlled devices are managed by Tier 2 AV APS devices.[305] Monitoring and controlling both active and standby power loads of controlled devices will reduce the overall load of a centralized group of electrical equipment (i.e. the home entertainment center). This more intelligent sensing and control process has been demonstrated to deliver increased energy savings and demand reduction compared with 'Tier 1 Advanced Power Strips'.

This measure was developed to be applicable to the following program types: DI. If applied to other program delivery types, the installation characteristics including the number of AV devices under control and an appropriate in service rate should be verified through evaluation.

Current evaluation is limited to Direct Install applications. Through a Direct Install program it can be assured that the APS is appropriately set up and the customer is knowledgeable about its function and benefit. It is encouraged that additional implementation strategies are evaluated to provide an indication of whether the units are appropriately set up, used with AV equipment and that the customer is knowledgeable about its function and benefit. This will then facilitate a basis for broadening out the deployment methods of the APS technology category beyond Direct Install.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is the use of a Tier 2 AV APS in a residential AV (home entertainment) environment that includes control of at least 2 AV devices with one being the television.[306]

The minimum product specifications for Tier 2 AV APS are:

Safety & longevity

- Product and installation instructions shall comply with 2012 International Fire Code and 2000 NFPA 101 Life Safety Code (IL Fire Code).
- Third party tested to all applicable UL Standards.
- Contains a resettable circuit breaker
- Incorporates power switching electromechanical relays rated for 100,000 switching cycles at full 15 amp load (equivalent to more than 10 years of use).

Energy efficiency functionality

- Calculates real power as the time average of the instantaneous power, where instantaneous power is the product of instantaneous voltage and current.
- Delivers a warning when the countdown timer begins before an active power down event and maintains the warning until countdown is concluded or reset by use of the remote or other specified signal
- Uses an automatically adjustable power switching threshold.

[305] Tier 2 AV APS identify when people are not engaged with their AV equipment and then remove power, for example a TV and its peripheral devices that are unintentionally left on when a person leaves the house or for instance where someone falls asleep while watching television.

[306] Given this requirement, an AV environment consisting of a television and DVD player or a TV and home theater would be eligible for a Tier 2 AV APS installation.

DEFINITION OF BASELINE EQUIPMENT

The assumed baseline equipment is the existing equipment being used in the home (e.g. a standard power strip or wall socket) that does not control loads of connected AV equipment.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The default deemed lifetime value for Tier 2 AV APS is assumed to be 7 years.[307]

DEEMED MEASURE COST

Direct Installation: The actual installed cost (including labor) of the new Tier 2 AV APS equipment should be used.

Baseline equipment cost if unknown is assumed to be $20[308].

LOADSHAPE

Loadshape R13 - Residential Standby Losses – Entertainment

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 80%.[309]

[307] There is little evaluation to base a lifetime estimate upon. Based on review of assumptions from other jurisdictions and the relative treatment of In Service Rates and persistence, an estimate of 7 years was agreed by the Technical Advisory Committee, but further evaluation is recommended.

[308] Price survey performed by Illume Advising LLC for IL TRM workpaper, see "Current Surge Protector Costs and Comparison 7-2016" spreadsheet.

[309] In the absence of empirical evaluation data, this was based on assumptions of the typical run pattern for televisions and computers in homes.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ERP * BaselineEnergy_{AV} * ISR$$

Where:

ERP = Energy Reduction Percentage of qualifying Tier2 AV APS product range as provided below. Savings are based upon independent field trials of two product manufacturers and the savings differences are assumed to relate to the product classifications provided below. Additional evaluation will be reviewed in future cycles to confirm if additional classification categories are appropriate.

Product Type	ERP used
Infrared Only	40%[310]
Infrared and Occupancy Sensor	25%[311]

$BaselineEnergy_{AV}$ = 466 kWh[312]

ISR = In Service Rate.

Product Type	ISR[313]
Infrared Only	73%
Infrared and Occupancy Sensor	83%

Deemed savings for each product type are provided below:

[310] Representative savings assumption based on the following independent field tests on Embertec's IR-only product. This includes both simulated saving results (based on recording what action the APS would have taken, but where equipment is not actually switched off allowing evaluation of the expected length of savings), and pre/post metering studies.

- AESC (page 30) - Valmiki, MM., Corradini, Antonio PE. 2015. *Tier 2 Advanced Power Strips in Residential and Commercial Applications*. Prepared for San Diego Gas & Electric by Alternative Energy Systems Consulting, Inc. (Simulated 50%, pre/post 32%).
- AESC- Valmiki, MM., Corradini, Antonio PE., Feb 2016. *Energy Savings of Tier 2 Advanced Power Strips in Residential AV Systems.* (Simulated 50%, pre/post 29%)
- CalPlug research (Page 12) - Wang, M. e. 2014. "*Tier 2 Advanced Power Strip Evaluation for Energy Saving Incentive".* California Plug Load Research Center (CalPlug), UC Irvine. (Simulated 51%)
- NMR Group Inc., *RLPNC 17-3: Advanced Power Strip Metering Study*, Revised March 18, 2019, submitted to Massachusetts Program Administrators and EEAC. (Pre/post with regression 50%, Pre/post only 20%).

[311] Representative savings assumption based on the following independent field tests on TrickeStar IR-OS product and reflect both simulated and pre/post meter study results.

- AESC- Valmiki, MM., Corradini, Antonio PE., Feb 2016. *Energy Savings of Tier 2 Advanced Power Strips in Residential AV Systems.* (Simulated 27%, pre/post 25%)
- NMR Group Inc., *RLPNC 17-3: Advanced Power Strip Metering Study*, Revised March 18, 2019, submitted to Massachusetts Program Administrators and EEAC. (Pre/post with regression 37%, Pre/post only 11%)

[312] Average of baseline energy in Regional Technical Form survey of Tier 2 APS pre-post methodology studies, see 'RTF_T2_APS.ppt'.

[313] Weighted average of evaluation results from AESC, Inc, "Energy Savings of Tier 2 Advanced Power Strips in Residential AC Systems", p35. These assumptions include "adjustments in weighting based on the persistence sensitivity to demographics" and NMR Group Inc., RLPNC 17-3: Advanced Power Strip Metering Study, Revised March 18, 2019.

Product Type	ΔkWh
Infrared Only	136.1
Infrared and Occupancy Sensor	96.7

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh / Hours * CF$$

Where:

ΔkWh = Energy savings as calculated above

Hours = Annual number of hours during which the APS provides savings.

= 4,380 [314]

CF = Summer Peak Coincidence Factor for measure

= 0.8 [315]

Deemed savings for each product type are provided below:

Product Type	ΔkW
Infrared Only	0.0249
Infrared and Occupancy Sensor	0.0177

FOSSIL FUEL SAVINGS

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

MEASURE CODE: RS-CEL-APS2-V06-240101

REVIEW DEADLINE: 1/1/2029

[314] This is estimate based on assumption that approximately half of savings are during active hours (supported by AESC study) (assumed to be 5.3 hrs/day, 1936 per year (NYSERDA 2011. "*Advanced Power Strip Research Report*")) and half during standby hours (8760-1936 = 6824 hours). The weighted average is 4380.

[315] In the absence of empirical evaluation data, this was based on assumptions of the typical run pattern for televisions and computers in homes. This appears to be supported by the Average Weekday AV Demand Profile and Reduction charts in the AESC study (p33-34). These show that the average demand reduction is relatively flat.

[316] Interactive effects of Tier 2 APS on space conditioning loads has not yet been adequately studied.

5.2.3 ENERGY STAR Television

DESCRIPTION

An ENERGY STAR[317] Certified television installed in place of a standard television.

This measure was developed to be applicable to the following program types: [TOS]. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as a television meeting the ENERGY STAR Version 9.0.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is defined as a non ENERGY STAR certified television.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of this measure is 5 years.[318]

DEEMED MEASURE COST

The incremental cost for this measure is $60.[319]

LOADSHAPE

R13: Residential Standby Losses - Entertainment

COINCIDENCE FACTOR

The coincidence factor for this measure is assumed to be 22%.[320]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

ENERGY STAR savings summarized in table below:[321]

Equipment Size Bin	ΔkWh
<=47.5"	93.2
47.5"<x<=52.5"	91.3
52.5"<x<=59.5"	71.6
59.5"<x<=69.5"	75.3
69.5"<x<=80"	31.7

[317] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[318] 'ENERGY STAR Version 9.0 TVs Data Package.xls'.
[319] Estimate from 'Savings Estimation Technical Reference Manual, 2017'. Highest cost estimate due to majority of TVs now being the larger bin sizes. This estimate is an old reference and would benefit a new study to improve the assumption.
[320] Based upon Hawai'i Energy, Technical Reference Manual, 2018
[321] 'ENERGY STAR Version 9.0 TVs Data Package.xls'.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh / Hours * CF

Where:

Hours = Estimate of hours savings achieved.

= 1759[322]

CF = Coincidence Factor

= 0.22[2]

Equipment Size Bin	ΔkW
<=47.5"	0.01166
47.5"<x<=52.5"	0.01142
52.5"<x<=59.5"	0.00896
59.5"<x<=69.5"	0.00942
69.5"<x<=80"	0.00396

MEASURE CODE: RS-CEL-TVS-V03-260101

REVIEW DEADLINE: 1/1/2028

[322] Most savings are achieved during "automatic brightness control" during active viewing. Recent study Nielsen "State of Play" found average viewing of 4.82 hours per day = 1759 hours per year.

5.2.4 Smart Sockets

DESCRIPTION

Smart sockets achieve savings through the reduction of the standby load of the controlled appliance, as well as eliminating the operation of an appliance during unoccupied hours. The standby power consumption of home appliances can be significantly reduced.

Smart Sockets in homes can be used for all types of appliances and significant saving opportunities exist for devices which are rarely unplugged like televisions, lamps, and speakers. The savings are derived from the times when the devices are not in use. Devices plugged in, even when off, consume electricity and smart sockets will reduce this standby load. In addition, smart sockets can be used to schedule equipment, so the load is less during hours which the devices are not in use.

This measure was developed to be applicable to the following program types: DI, KITS

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is the use of a smart plug with a standby power wattage of 2W or less. Should be UL listed. (Simply Conserve Smart Socket SS-15A1-WiFi has a standby power of less than or equal to 0.7).

DEFINITION OF BASELINE EQUIPMENT

The assumed baseline is an appliance plugged into an outlet or into a standard power strip with surge protection that does not control connected loads. Note many ENERGY STAR appliances require power saving settings which will partially offset the savings potential of this measure. Where possible non-ENERGY STAR equipment should be plugged in to the socket to ensure savings are realized.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of the smart socket is 7 years.

DEEMED MEASURE COST

For direct install, the actual full equipment and installation cost (including labor) and for kits the actual full equipment cost should be used. If unknown for kits, use $19.99/each[323].

LOADSHAPE

Loadshape R13 – Standby Losses – Entertainment Center

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 80%.[324]

[323] Based on cost from vendor of typical smart socket on the market, Simply Conserve Smart Socket by AM Conservation Group.; 15 amp smart socket: $19.99/each.

[324] Efficiency Vermont 2016 TRM coincidence factor for advanced power strip measure –in the absence of empirical evaluation data, this was based on assumptions of the typical run pattern for televisions and computers in homes.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \frac{((W_{Base} * OnAdj) - W_{Eff}) * Hours}{1{,}000} * ISR$$

Where:

W_{Base}[325] = Standby power or On power consumption of connected appliance.

Use actual if known, or refer to tables below. If unknown, e.g. via kits, assume 9.4W

Appliances assumed to be in standby mode:

Controlled Equipment[326]	Standby Power (W)
Coffee Maker	1.14
Television, CRT	3.06
Television, Rear Projection	6.97
Television, LCD[327]	8.00
Set-top Box, DVR	36.68
Set-top Box, Digital Cable	17.83
Set-top Box, Satellite	15.66
Television/VCR	5.99
VCR	4.68
Computer, Desktop	2.84
Computer Notebook	8.90
Multifunction Device, Inkjet	5.26
Multifunction Device, Laser	3.12
Scanner, Flatbed	2.48

Appliances assumed to be in on mode:

Controlled Equipment[328]	On Power (W)
Light	10.4
Fan	70
Space Heater	450

OnAdj[329] = Adjustment for wattages of appliances that are powered on during unoccupied hours

= 50% for appliances in on mode

[325] Average connected wattage found in Guidehouse, 'ComEd Small Business Kits CY2020 Impact Evaluation Report 2021-04-01 Final.pdf'.

REVIEW DEADLINE: 1/1/2029

5.3 HVAC End Use

5.3.1 Air Source Heat Pumps (Centrally Ducted, Ductless and Portable)

DESCRIPTION

A heat pump provides heating or cooling by moving heat between indoor and outdoor air. This measure relates to:

- a unitary central heat pump (split or packaged) with conditioned air delivered to the home via ductwork
- a ductless minisplit system
- "hybrid" systems that work in conjunction with fuel-fired heating systems, and
- a portable heat pump (mounted within a wall, within a window, or floor-mounted with intake and/or exhaust duct(s) directed through a window).

This measure characterizes:

a) New Construction:
   - The installation of a new residential sized (<= 65,000 Btu/hr) Air Source Heat Pump meeting minimum requirements determined by the program in a new home.
   - Note the baseline in this case should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition.

b) Time of Sale:
   - The installation of a new residential sized (<= 65,000 Btu/hr) Air Source Heat Pump meeting minimum requirements determined by the program. This relates to the replacement of an existing unit at the end of its useful life.
   - Note the baseline in this case is an equivalent replacement system to that which exists currently in the home. Where unknown, the baseline should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition.
   - The allocation of savings is dependent on whether an incentive for the installation has been provided by both a gas and electric utility, just an electric utility or just a gas utility.

c) Early Replacement:

   The early removal of functioning components of the electric or gas heating and/or cooling systems from service, prior to its natural end of life, and replacement with a new high efficiency air source heat pump unit.

   Note the baseline in this case is the existing equipment being replaced. The allocation of savings is dependent on whether an incentive for the installation has been provided by both a gas and electric utility, just an electric utility or just a gas utility.

   Early Replacement determination will be based on meeting the following conditions:
   - The existing unit is operational when replaced, or
   - The existing unit requires minor repairs (<$276 per ton).[332]
   - All other conditions will be considered Time of Sale.

   The Baseline SEER2 of the existing unit replaced:
   - Is the actual SEER (converted to SEER2) value of the unit replaced.
   - If the SEER of the existing unit is unknown use assumptions in variable list below (SEER2_exist and HSPF2_exist).

[332] The Technical Advisory Committee agreed that if the cost of repair is less than 20% of the new baseline replacement cost it can be considered early replacement. Note the non-inflated cost is used as this would be a cost consideration in the program year.

- If the operational status or repair cost of the existing unit is unknown, use time of sale assumptions or average weighted factors determined via evaluation and the algorithms below.

A weighted average early replacement rate is provided for use in programs when the actual baseline early replacement rates are unknown.

Deemed Early Replacement Rates For ASHP[333]

Equipment Type	Full System Displacement	Partial System Displacement
Cooling	30%	30%
Heating	30%	100%

Note to apply these deemed early replacement rates, an assumption of the percentage of replacements that are full displacement v partial displacement is required. If the program design requires cold climate heat pumps, sizes heating equipment to handle the full heating load of the living unit, 100% full displacement can be used. Otherwise the split of full vs partial displacement should be determined through evaluation, or a deemed ratio of 100% Full Displacement for ducted ASHPs and 50% Full: 50% Partial for Ductless ASHPs can be used[334]. Savings should be calculated following both the full and partial displacement methodology and then this ratio should be used to weight the savings accordingly.

Quality Installation:

Additional savings are attributed to the Quality Installation (QI) of the system. QI programs should follow industry standards such as those described in ENERGY STAR Verified HVAC Installation Program (ESVI), ANSI ACCA QI5 and QI9vp. This must include considerations of system design (including sizing, matching, ventilation calculations) and equipment installation (including static pressure, airflow, refrigerant charge) and may also consider distribution.

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

A new residential sized (<= 65,000 Btu/hr) air source heat pump with specifications to be determined by program.

The following conversion factors are recommended for use if the efficient equipment is not rated under the new testing procedure:[335]

SEER2 = SEER * X

EER2 = EER * X

HSPF2 = HSPF * X

[333] Program tracking data from ComEd and Ameren between 2018 and 2020 was used to develop these assumptions. During this period the air source heat pump programs operated downstream and projects were classified as Time of Sale or Early Replacement. Note that any fuel switch scenario at the time would have been classified as Time of Sale and therefore the rates provided likely represent a low estimate of the true early replacement rates. In the absence of alternative data, the TAC agreed to apply these rates and the deemed full v partial displacement assumptions listed, but these assumptions should be revisited through future evaluation.

[334] For ductless ASHPs with a capacity less than 18kBtu, the Full Displacement calculation should use the lower 'Supplemental' EFLHs provided, and the Partial Displacement calculation use the Standard hours. All other calculations should use the Standard hours. We assume that smaller systems are typically used to (1) provide all of the heating/cooling for zones outside of central living zones or (2) as partial displacement of existing systems in central living zones.

[335] Consortium for Energy Efficiency (CEE), Testing, Testing, M1, 2, 3, Transitioning to New Federal Minimum Standards, CEE Summer Program Meeting, August, 2022.

Where:

X	SEER	EER	HSPF
Ducted	0.95	0.95	0.85
Non-Ducted	1.00	1.00	0.90
Packaged/Portable	0.95	0.95	0.84

DEFINITION OF BASELINE EQUIPMENT

The baseline designation can be assigned differently for heating and cooling for the same installation, but the designation must remain consistent when applying the TRM calculations (e.g., for energy savings, measure cost, and demand savings). For example, customers may choose to replace an AC at the end of its useful life yet continue using their existing furnace. In this case, the cooling replacement could represent a time of sale baseline while the heating replacement could reflect an early replacement baseline.

New Construction: To calculate savings with an electric baseline, the baseline equipment is assumed to be an Air Source Heat Pump meeting the Federal Standard efficiency level:[336]

- Split system ducted heat pump standard sized units – 14.3 SEER2, 7.5 HSPF2, 9.4 EER2
- Split system ductless heat pump standard sized units – 14.3 SEER2, 7.5 HSPF2, 8.5 EER2
- Space constrained heat pump units – 11.9 SEER2, 7.8 EER2 and 6.3 HSPF2

Note, the space constrained product baseline should only be used when the efficient unit is classified as space constrained (labelled as SCP on AHRI database).

To calculate savings with a furnace/central AC baseline, the baseline equipment is assumed to be an 80% AFUE Furnace and central AC meeting the Federal Standard efficiency level; 13.4 SEER2, 10.6 EER2 for standard sized units, or 11.7SEER, 9.2 EER2 for space constrained product.

Time of Sale: The baseline for this measure is a new replacement unit of the same system type as the existing unit, meeting the baselines provided below[337].

Unit Type	Efficiency Standard
Standard sized Ducted ASHP	14.3 SEER2, 9.4 EER2, 7.5 HSPF2
Standard sized Ductless ASHP	14.3 SEER2, 8.5 EER2, 7.5 HSPF2
Space constrained ASHP	11.9 SEER2, 7.8 EER2, 6.3 HSPF2
Room AC (baseline applicable for portable HP or mobile homes only)	Select appropriate baseline from measure 5.1.7. Assume same capacity as efficient.
Electric Resistance (Baseboard or Electric Furnace) (Default for portable HP)	3.412 HSPF2
Natural Gas or LP Furnace	80% AFUE
Natural Gas or LP Boiler	84% AFUE
Oil Furnace	83% AFUE
Oil Boiler	86% AFUE

[336] The federal Standard does not currently include an EER2 component for northern states. The value provided is based on scaling CEE Tier 1 ratings for North and Canada (12EER2 for CAC, 10EER2 for ducted HP and 9.0EER2 for ductless HP) proportionally down compared to the Federal baseline SEER2 compared to CEE Tier 1 SEER2 ratings.
[337] Federal Standard as provided in DOE 10 CFR 430.32.

Unit Type	Efficiency Standard
Standard sized Central AC	13.4 SEER2, 10.6 EER2
Space constrained Central AC	11.7 SEER2, 9.2 EER2
Unknown, installing ducted [338]	13.9 SEER2, 9.4 EER2, 5.9HSPF2, 80.1% AFUE
Unknown, installing ductless	13.7 SEER2, 8.5 EER2, 5.3HSPF2, 81.1% AFUE

Early replacement / Retrofit: The baseline for this measure is the efficiency of the *existing* heating and cooling equipment for the assumed remaining useful life of the existing unit and a new baseline heating and cooling system for the remainder of the measure life (as provided in table above).

When unknown, default early replacement efficiency assumptions are 9.2 SEER2, 7.4 EER2, 4.5 HSPF2 and 80% AFUE when installing ducted ASHP and 9.5 SEER2, 7.4 EER2, 4.4 HSPF2 and 63% AFUE when installing ductless[339]. Consistent with TRM Volume 1 Section 2.3.1 for midstream programs or other cases where the existing condition is unknown, it may be appropriate to apply a deemed percent split of Time of Sale and Early Replacement assumptions based on evaluation results.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 16 years for ducted and ductless ASHP[340] and 12 years for portable HP[341].

Remaining life of existing equipment is assumed to be 6 years for ASHP and Central AC, 6 years for furnace, 8 years for boilers[342] and 16 years for electric resistance.[343]

DEEMED MEASURE COST

New Construction and Time of Sale: The actual installed cost of the Centrally Ducted Air Source Heat Pump or Ductless Minisplit Heat Pump (including any necessary electrical or distribution upgrades required) should be used minus the assumed installation cost of the baseline equipment from table below for electric baseline equipment, or assume $4,019 for a new baseline 80% AFUE furnace or $8,820 for a new baseline 84% AFUE boiler[344].

[338] Unknown time of sale baseline values represent the weighted average baseline values (in SEER2/HSPF2/AFUE) reflecting the assumed shares of installed ASHP replacing given baseline technologies (e.g. ASHP/electric resistance or furnace/boiler) by fuel type. Assumed shares are based on Opinion Dynamics and Guidehouse analysis of 2018-2021 Ameren and ComEd HVAC (downstream) program tracking data, converted to SEER2/EER2/HSPF2 using conversion factors provided. For further details, see '2018-2021 AIC Res HVAC Data ASHP Baseline TRM Update 2023-6-20.xls'.

[339] Unknown early replacement baseline values represent the weighted average existing system efficiency values (converted to SEER2/HSPF2 using conversion factors provided) reflecting the assumed shares of installed ASHP replacing given baseline technologies (e.g. ASHP/electric resistance or furnace/boiler) by fuel type. Assumed shares are based on Opinion Dynamics and Guidehouse analysis of 2018-2021 Ameren and ComEd HVAC (downstream) program tracking data. For further details, see '2018-2021 AIC Res HVAC Data ASHP Baseline TRM Update 2023-6-20.xls'.

[340] Based on 2016 DOE Rulemaking Technical Support document, as recommended in Guidehouse 'ComEd Effective Useful Life Research Report', May 2018.

[341] Assumed the same as 5.1.7 Window Air Conditioners: Measure Life Report, Residential and Commercial/Industrial Lighting and HVAC Measures, GDS Associates, June 2007.

[342] Assumed to be one third of effective useful life of replaced equipment.

[343] Assume full measure life (16 years) for replacing electric resistance as we would not expect that resistance heat would fail during the lifetime of the efficient measure.

[344] In 2025, a working group was created to update costs for residential HVAC equipment. Heat Pump and Central Air Conditioning costs are based upon Ameren program data. Furnace and Boiler costs are based on Ameren, Nicor, People's Gas, and North Shore Gas program data. Baseline costs have been determined using ratios from Updated Buildings Sector Appliance and Equipment Costs and Efficiencies by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration, March 2023. See file "HVAC Costs – 071825_VEIC.xlsx" for more details.

Baseline Equipment Type	Capacity Range	Baseline Cost per Ton[345]
Centrally Ducted Air Source Heat Pumps	< 2 tons	$4,602
	≥ 2 to < 3 tons	$3,691
	≥ 3 to < 4 tons	$3,093
	≥ 4 tons	$2,992
Ductless Minisplit Heat Pumps	< 1 ton	$8,156
	≥ 1 to < 2 tons	$5,356
	≥ 2 to < 3 tons	$3,704
	≥ 3 tons	$3,670
Central Air Conditioning	< 2 tons	$2,340
	≥ 2 to < 3 tons	$1,900
	≥ 3 tons	$1,500

Default full cost of the efficient Centrally Ducted ASHP or DMSHP is provided in the table below[346]:

Equipment Type	Capacity Range	Efficient Cost
Centrally Ducted Air Source Heat Pumps	< 2 tons	$4,689 / ton + ($600* (HSPF2-7.8))
	≥ 2 to < 3 tons	$3,762 / ton + ($600* (HSPF2-7.8))
	≥ 3 to < 4 tons	$3,152 / ton + ($600* (HSPF2-7.8))
	≥ 4 tons	$3,049 / ton + ($600* (HSPF2-7.8))
Ductless Minisplit Heat Pumps	< 1 ton	$8,312 / ton + ($600* (HSPF2-7.8))
	≥ 1 to < 2 tons	$5,458 / ton + ($600* (HSPF2-7.8))
	≥ 2 to < 3 tons	$3,775 / ton + ($600* (HSPF2-7.8))
	≥ 3 tons	$3,740 / ton + ($600* (HSPF2-7.8))

The incremental cost of the Centrally Ducted ASHP or DSMHP compared to a baseline minimum efficiency Centrally Ducted ASHP or DSMHP is provided in the table below:

Equipment Type	Capacity Range	Incremental Cost
Centrally Ducted Air Source Heat Pumps	< 2 tons	$88 / ton + ($600* (HSPF2-7.8))
	≥ 2 to < 3 tons	$70 / ton + ($600* (HSPF2-7.8))
	≥ 3 to < 4 tons	$59 / ton + ($600* (HSPF2-7.8))
	≥ 4 tons	$57 / ton + ($600* (HSPF2-7.8))
Ductless Minisplit Heat Pumps	< 1 ton	$156 / ton + ($600* (HSPF2-7.8))
	≥ 1 to < 2 tons	$102 / ton + ($600* (HSPF2-7.8))
	≥ 2 to < 3 tons	$71 / ton + ($600* (HSPF2-7.8))
	≥ 3 tons	$70 / ton + ($600* (HSPF2-7.8))

Early Replacement: The actual full installation cost of the Centrally Ducted Air Source Heat Pump or Ductless Minisplit Heat Pump (including any necessary electrical or distribution upgrades required) should be used (defaults provided above). The assumed deferred cost (after the appropriate number of years described above in the 'Deemed Lifetime of Efficient Equipment' section) of replacing existing equipment with a new baseline unit is presented in the table below for electric equipment or assume $4,601 for a new baseline 80% AFUE furnace or $10,563 for a new baseline 84% AFUE boiler[347]. If replacing electric resistance heat, there is no deferred replacement cost. This future cost should be discounted to present value using the nominal societal discount rate. Where a DMSHP is a supplemental HVAC system, the full installation cost of the DMSHP (including any necessary electrical or distribution upgrades required) should be used without a deferred replacement cost.

[345] Ibid

[346] Ibid

[347] All baseline replacement costs are consistent with their respective measures and include inflation rate of 2.28%.

Equipment Type	Capacity Range	Deferred Baseline Cost per Ton
Centrally Ducted Air Source Heat Pumps	< 2 tons	$5,268
	≥ 2 to < 3 tons	$4,226
	≥ 3 to < 4 tons	$3,541
	≥ 4 tons	$3,425
Ductless Minisplit Heat Pumps	< 1 ton	$9,337
	≥ 1 to < 2 tons	$6,132
	≥ 2 to < 3 tons	$4,240
	≥ 3 tons	$4,202
Central Air Conditioning	< 2 tons	$2,679
	≥ 2 to < 3 tons	$2,175
	≥ 3 tons	$1,717

Portable Heat Pumps:

The actual installed cost of the portable heat pump (including any necessary electrical or distribution upgrades required) should be used, minus the assumed installation cost of the baseline cooling and heating system. If portable heat pump cost is unknown assume $645 per unit.[348] The cost of a baseline replacement room AC unit is $408.[349]

Fuel switch scenarios are likely to require additional installation work which may include adding new electrical circuits, capping existing gas lines and upgrading electrical panels. These costs are likely to range significantly and actual values should be used wherever possible. If unknown, assume an additional $2,000 for full displacement fuel switch installations and $300 for partial displacement installations.

The total of any additional electrification costs should be divided across all applicable measures weighted by total MMBtu savings.

Quality Installation: The additional design and installation work associated with quality installation has been estimated to cost an additional $150.[350]

LOADSHAPE

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's Forward Capacity Market.

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during utility peak hour)

= 72%[351]

[348] Average retail cost of ENERGY STAR certified portable heat pumps, as of 6/2024 and collected by Ameren. See 'PHP Cost and Efficiencies 20240605.xls'.
[349] Based upon costs provided in 5.1.7 ENERGY STAR and CEE Tier 2 Room Air Conditioner.
[350] Based on data provided by MidAmerican in April 2018 summarizing survey results from 11 HVAC suppliers in Iowa.
[351] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[352]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[353]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS AND FOSSIL FUEL SAVINGS

Non fuel switch measures (if heat pump is being installed for cooling only, only calculate the cooling impact below):

$\Delta kWh_{Non\ Fuel\ Switch}$ = ASHPSiteCoolingImpact + ASHPSiteHeatingImpact + ElectricFurnaceFanSavings

Where:

ASHPSiteCoolingImpact = ((CoolingLoad/DuctlessSave * (1/(SEER2_base * (1 – $DeratingCool_{Base}$)))) – (CoolingLoad * 1/(SEER2_ee * (1 – $DeratingCool_{Eff}$))))/1000

ASHPSiteHeatingImpact = ((HeatLoad_Disp/DuctlessSave * (1/(HSPF2_base * HSPF2_ClimateAdj * (1 – $DeratingHeat_{Base}$)))) – (HeatLoad_Disp * 1/(HSPF2_ee * HSPF2_ClimateAdj * (1 – $DeratingHeat_{Eff}$)))) / 1000

ElectricFurnaceFanSavings[354] = FurnaceFlag * ASHPSiteHeatingImpact * F_e

Fuel switch measures:

Fuel switch measures must produce positive total lifecycle energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

SiteEnergySavings (MMBTUs) = FuelSwitchSavings + NonFuelSwitchSavings

FuelSwitchSavings = GasHeatReplaced – ASHPSiteHeatConsumed

NonFuelSwitchSavings = GasFurnaceFanSavings + ASHPSiteCoolingImpact

Where:

GasHeatReplaced = (HeatLoad_Disp/DuctlessSave * 1/$AFUE_{base}$) / 1,000,000

[352] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[353] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

[354] If replacing an electric furnace only. The HSPF rating of a heat pump accounts for the fan consumption, however the HSPF rating of an electric furnace does not. Therefore, additional fan savings should be claimed.

GasFurnaceFanSavings = (FurnaceFlag * HeatLoad_Disp/DuctlessSave * 1/$AFUE_{base}$ * F_e) / 1,000,000

ASHPSiteHeatConsumed = ((HeatLoad_Disp * (1/(HSPF2_ee * HSPF2_ClimateAdj * PD_Adj * (1 – $DeratingHeat_{Eff}$)))) /1000 * 3412)/ 1,000,000

ASHPSiteCoolingImpact = ((CoolingLoad/DuctlessSave * (1/(SEER2_base * (1 – $DeratingCool_{Base}$)))) – ((CoolingLoad * 1/(SEER2_ee * (1 – $DeratingCool_{Eff}$))))/1000 * 3412) / 1,000,000

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Note for Early Replacement measures, the efficiency (SEER, EER and HSPF) and furnace fan energy consumption (F_e) terms of the existing unit should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 7 years for furnace, 8 years for boilers, 16 years for electric resistance), and the efficiency and F_e terms for a new baseline unit should be used for the remaining years of the measure. See assumptions below.

Programs where existing system is unknown

In programs where the existing fuel or system type is unknown, savings should be apportioned between the Fuel Switch and Non- Fuel Switch scenarios, as follows:

Savings from Non-Fuel Switch (kWh) = (1 – %FuelSwitch) * $\Delta kWh_{Non\ Fuel\ Switch}$

Plus

Savings from Fuel Switch (MMBtu converted to appropriate fuel as table above)

= %FuelSwitch * SiteEnergySavings (MMBTUs)

Where:

%FuelSwitch = The percentage of replacements resulting in fuel-switching.

= 1 when fuel switching is known, 0 if non fuel switch

= when unknown, e.g. midstream program, determine via evaluation

CoolingLoad = Annual cooling load for the building

= FLH_cooling * Capacity_ASHPcool

FLH_cooling = Full load hours of air conditioning

= dependent on location:

Climate Zone (City based upon)	FLH_cooling (single family) [355]	FLH_cooling (multifamily) [356]	FLH_cooling [357] (Ductless Minisplit HP providing supplemental cooling or Portable HP in IQ homes)[358]	FLH_cooling (Portable HP in non-IQ homes)[359]
1 (Rockford)	547	499	331	235
2 (Chicago)	709	629	429	261
3 (Springfield)	779	707	472	340
4 (Belleville)	1082	982	655	447
5 (Marion)	956	868	579	396
Weighted Average[360]				
ComEd	676	603	409	256
Ameren	875	791	530	364
Statewide	731	655	443	286

Use Multifamily if: Building has meets utility's definition for multifamily and system serves single unit. For residential sized systems serving 2 or more units, assume single family hours. For central systems use Volume 2 Commercial and Industrial Measures.

Capacity_ASHPcool = Cooling Output Capacity of Air Source Heat Pump (Btu/hr)

= Actual (1 ton = 12,000Btu/hr)

DuctlessSave = Factor used to adjust ducted heating or cooling load displaced by ductless or portable HP systems that are not subject to losses from existing ductwork.

= 1-0.15 = 0.85 for ducted system displaced by ductless or portable HP system

= 1.00 for ducted system displaced by ducted system or ductless system displaced by ductless or portable HP system

SEER2_base = Seasonal Energy Efficiency Ratio of baseline unit (kBtu/kWh), converted to SEER2 if rating is in SEER. For early replacment measures, the actual SEER2 rating where it is possible to measure or reasonably estimate should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[361] or if unknown assume default provided below. If unknown value is used, it should not be derated by age.

[355] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values

[356] Ibid.

[357] Full load hours for a ductless minisplit HP providing supplemental cooling to a limited space previously unserved or underserved by existing equipment, is based on the ratio of the EFLH for conventional cooling systems to the EFLH of DMSHPs provided in the "Ductless Mini Split Heat Pump Impact Evaluation" 2016, The Cadmus Group, pg. 6 (61%).

[358] If unknown, assume supplemental if ductless minisplit heat pump <18,000 Btu/h.

[359] Full load hours for non-IQ portable heat pumps is assumed to be consistent with Room AC EFLHs.

[360] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[361] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

Baseline/Existing Cooling System	SEER2_base		
	Early Replacement (Remaining useful life of existing equipment)	Early Replacement (Remaining measure life)	Time of Sale or New Construction
Air Source Heat Pump – Standard sized	9.2 SEER2[362]	14.3 SEER2[363]	
Air Source Heat Pump – Space constrained	9.2 SEER2	11.9 SEER2	
Central AC – Standard sized	9.2 SEER2[364]	13.4 SEER2[365]	
Central AC – Space constrained	9.2 SEER2	11.7 SEER2	
Room AC[366] (baseline applicable for portable HP or mobile homes only) Non-IQ IQ	 10.9 CEER 8.7 CEER	Select appropriate baseline from measure 5.1.7. Assume same capacity as efficient. If unknown assume 10.9 CEER.	
No central cooling	Make '1/SEER2_exist' = 0[367]	13.4 SEER2[368]	
Unknown, installing ducted[369]	9.2 SEER2	13.9 SEER2	
Unknown, installing ductless	9.5 SEER2	13.7 SEER2	

SEER2_ee = Rated Seasonal Energy Efficiency Ratio of ENERGY STAR[370] unit (kBtu/kWh), converted to SEER2 if rating is in SEER (or CEER for portable heat pumps)
= Actual or program-defined minimum if unknown.

$DeratingCool_{Eff}$ = Efficent ASHP Cooling derating

= 0% if Quality Installation is performed

= $DeratingCool_{Base}$ if Quality Installation is not performed or unknown[371]

$DeratingCool_{Base}$ = Baseline Cooling derating

= If ducted heating or cooling load is being replaced by ductless or portable HP systems

[362] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018', converted to SEER2.
[363] Minimum Federal Standard as of 1/1/2023
[364] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018' Converted to SEER2.
[365] Minimum Federal Standard; Federal Register, Vol. 66, No. 14, Monday, January 22, 2001/Rules and Regulations, p. 7170-7200.
[366] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026. For IQ participants this is more likely to be the least efficient units so is consistent with the early replacement baseline from 5.1.7 ENERGY STAR and CEE Tier 2 Room Air Conditioner.
[367] If there is no central cooling in place but the incentive encourages installation of a new ASHP with cooling, the added cooling load should be subtracted from any heating benefit.
[368] Assumes that the decision to replace existing systems includes desire to add cooling.
[369] Values represent the weighted average SEER baseline values (converted to SEER2) reflecting the assumed shares of installed ASHP replacing given baseline technologies (e.g. ASHP/electric resistance or furnace/boiler) by fuel type. Assumed shares are based on Opinion Dynamics and Guidehouse analysis of 2018-2021 Ameren and ComEd HVAC (downstream) program tracking data. For further details, see '2018-2021 AIC Res HVAC Data ASHP Baseline TRM Update 2023-06-20.xls'.
[370] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[371] Based on Cadmus assumption provided in preparation of the 2014 Interstate Power and Light TRM based upon proper refrigerant charge, evaporator airflow, and unit sizing. Appears conservative in comparison to ENERGY STAR statements (see 'Sponsoring an ENERGY STAR Verified HVAC Installation (ESVI) Program') and so could be considered for future evaluation.

that are not subject to losses from existing ductwork, assume 5% as DuctlessSave term accounts for distribution benefits

= 10%

HeatLoad_Disp = Annual heat load for the building displaced by the ASHP (Btus)

= FLH_ASHPheat * Capacity_ASHPheat * HeatLoadFactor

FLH_ASHPheat = Full load hours of heat pump heating

= Dependent on location and home type:

Climate Zone (City based upon)	FLH_ ASHPheat (single family and multifamily)[372]	FLH_ ASHPheat [373] (Ductless Minisplit HP providing supplemental heating or Portable HP)[374]
1 (Rockford)	1924	716
2 (Chicago)	1726	642
3 (Springfield)	1708	636
4 (Belleville)	1195	445
5 (Marion/Murphysboro)	1270	473
Weighted Average[375]		
ComEd	1766	657
Ameren	1547	576
Statewide	1700	633

Capacity_ASHPheat = Heating Output Capacity of Air Source Heat Pump at 47° F (Btu/hr)

= Actual (1 ton = 12,000Btu/hr)

HeatLoadFactor = Portion of HeatLoad displaced by ASHP in partial displacement applications. Varies by Switchover Temperature and Climate Region. If Switchover Temperature is unknown, use 32F. For portable heat pumps, unless it can be confirmed that the unit will be used through the heating season, use 47F to reflect likely behavior of unit being removed when temperature falls below this temperature.

= 1.0 if full displacement (e.g. cold climate heat pumps) or if switchover temperature is lower than 17F, if Partial Displacement with simultaneous operation.

[372] Full load heating hours for heat pumps are provided for Rockford, Chicago and Springfield in the ENERGY STAR Calculator. Estimates for the other locations were calculated based on the FLH to Heating Degree Day (from NCDC) ratio. VEIC consider ENERGY STAR estimates to be high due to oversizing not being adequately addressed. Using average Illinois billing data (from ICC Commerce Commission) VEIC estimated the average gas heating load and used this to estimate the average home heating output (using 83% average gas heat efficiency). Dividing this by a typical 36,000 Btu/hr ASHP gives an estimate of average ASHP FLH_heat of 1821 hours. We used the ratio of this value to the average of the locations using the ENERGY STAR data (1994 hours) to scale down the ENERGY STAR estimates. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of HDD60, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHheat values

[373] Full load hours for a ductless minisplit HP providing supplemental heating to a limited space previously unserved or underserved by existing equipment, is based on the ratio of the EFLH for conventional heating systems to the EFLH of DMSHPs provided in the "Ductless Mini Split Heat Pump Impact Evaluation" 2016, The Cadmus Group, pg. 6 (37%).

[374] If unknown, assume supplemental if ductless minisplit heat pump <18,000 Btu/h.

[375] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

Climate Zone (City based upon)	HeatLoadFactor (by Switchover Temperature)										
	47F	44F	41F	38F	35F	32F	29F	26F	23F	20F	17F
1 (Rockford)	8%	14%	18%	22%	32%	42%	50%	63%	70%	74%	81%
2 (Chicago)	8%	14%	20%	26%	37%	48%	56%	70%	77%	80%	86%
3 (Springfield)	8%	15%	21%	27%	43%	57%	63%	73%	79%	82%	87%
4 (Belleville)	13%	21%	30%	37%	48%	61%	71%	80%	88%	92%	95%
5 (Marion)	14%	23%	33%	41%	59%	72%	79%	88%	92%	95%	97%
Weighted Average[376]											
ComEd	8%	14%	20%	26%	37%	48%	56%	70%	77%	80%	86%
Ameren	10%	16%	24%	30%	44%	57%	64%	75%	81%	85%	90%
Statewide	8%	15%	21%	27%	39%	50%	58%	71%	78%	81%	87%

HSPF2_base = Heating Seasonal Performance Factor 2 of baseline heating system (kBtu/kWh), converted to HSPF2 if rating is in HSPF. For early replacement measures, use actual HSPF2 rating where it is possible to measure or reasonably estimate for the remaining useful life of the existing equipment (6 years for ASHP, 16 years for electric resistance). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[377] or if unknown assume default. If unknown value is used, it should not be derated by age.

Baseline/ Existing Heating System	HSPF2_base		
	Early Replacement (Remaining useful life of existing equipment)	Early Replacement (Remaining measure life)	Time of Sale or New Construction
Air Source Heat Pump – standard sized	4.91 HSPF2[378]	7.5 HSPF2[379]	
Air Source Heat Pump – space constrained	4.91 HSPF2	6.3 HSPF2	
Electric Resistance (Baseboard or Electric Furnace)	3.41 HSPF2[380]		
Unknown, installing ducted[381]	4.5 HSPF2	5.9 HSPF2	
Unknown, installing ductless	4.4 HSPF2	5.3 HSPF2	

HSPF2_ee = Heating Seasonal Performance Factor 2 of efficient Air Source Heat Pump, converted to HSPF2 if rating is in HSPF (kBtu/kWh)

[376] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[377] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[378] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018' Converted to HSPF2.

[379] Based on Minimum Federal Standard effective 1/1/2023.

[380] Electric resistance has a COP of 1.0 which equals 1/0.293 = 3.41 HSPF.

[381] Values represent the weighted average HSPF (converted to HSPF2) baseline values reflecting the assumed shares of installed ASHP replacing given baseline technologies (e.g. ASHP/electric resistance or furnace/boiler) by fuel type. Assumed shares are based on Opinion Dynamics and Guidehouse analysis of 2018-2021 Ameren and ComEd HVAC (downstream) program tracking data. For further details, see '2018-2021 AIC Res HVAC Data ASHP Baseline TRM Update 2023-06-20.xls'.

= Actual or program-defined minimum if unknown[382]

$DeratingHeat_{Eff}$ = Efficent ASHP Heating derating

= 0% if Quality Installation is performed

= 10% if Quality Installation is not performed[383]

$DeratingHeat_{Base}$ = Baseline Heating derating

= 10%

HSPF2_ClimateAdj= Adjustment factor to account for observed discrepency between seasonal heating performance relative to rated HSPF2 as provided by standard AHRI 210/240 rating conditions.[384]

= 100% if Partial Displacement and switchover temperature greater than 17F, otherwise:

City (county based upon)	HSPF2_ClimateAdj
1 (Rockford)	77%
2 (Chicago)	77%
3 (Springfield)	91%
4 (Belleville)	91%
5 (Marion)	91%
Weighted Average[385]	
ComEd	77%
Ameren	89%
Statewide	80%

PD_Adj = Adjustment multiplier to account for increased heat pump efficiency in Partial Displacement applications when there is no electric resistance backup and switchover temperature is higher than 17F. Varies by Switchover Temperature and Climate Region. If Switchover Temperature is unknown, use 32F.

= 1.0 if full displacement (e.g. cold climate heat pumps) or if switchover temperature is lower than 17F, or if Partial Displacement with simultaneous operation, or if Portable HP.

[382] ENERGY STAR minimum.

[383] Based on Cadmus assumption provided in preparation of the 2014 Interstate Power and Light TRM based upon proper refrigerant charge, evaporator airflow, and unit sizing, Assumed consistent for heating and cooling. Appears conservative in comparison to ENERGY STAR statements (see 'Sponsoring an ENERGY STAR Verified HVAC Installation (ESVI) Program') and so could be considered for future evaluation.

[384] Adjustment factors are based on findings from NEEA, July 2020 'EXP07:19 Load-based and Climate-Specific Testing and Rating Procedures for Heat Pumps and Air Conditioners'. See 'NEEA HP data' for calculation. Findings were consistent with other reviewed sources including ASHRAE, 2020 'Right-Sizing Electric Heat Pump and Auxiliary Heating for Residential Heating Systems Based on Actual Performance Associated with Climate Zone' and Cadmus, 2022 'Residential ccASHP Building Electrification Study'. The difference between HSPF and HSPF2 ratings is based on the change in testing procedure that will correct for some of this effect where ducted systems will have an approximately 9% lower HSPF2 rating as compared to HSPF, based on CEE presentation, July 2022, 'Testing Testing, M1, 2, 3: Transitioning to New Federal Minimum Standards'.

[385] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

Climate Zone (City based upon)	PD_Adj (by Switchover Temperature)										
	47F	44F	41F	38F	35F	32F	29F	26F	23F	20F	17F

Weighted Average[386]											
ComEd	155%	151%	147%	144%	140%	137%	134%	131%	129%	128%	126%
Ameren	155%	151%	147%	145%	140%	137%	135%	132%	130%	129%	128%
Statewide	155%	151%	147%	144%	140%	137%	134%	131%	129%	128%	126%

$AFUE_{base}$ = Baseline Annual Fuel Utilization Efficiency Rating. For early replacement measures, use actual AFUE rating where it is possible to measure or reasonably estimate for the remaining useful life of the existing equipment (6 years for furnace, 8 years for boilers). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[387] or if unknown assume default. If unknown value is used, it should not be derated by age.

Baseline/ Existing Heating System	AFUEbase		
	Early Replacement (Remaining useful life of existing equipment)[388]	Early Replacement (Remaining measure life)	Time of Sale or New Construction
Furnace	64.4%	80%	80%
Boiler	61.6%	84%	84%
Unknown, installing ducted [389]	80%	80.1%	80.1%
Unknown, installing ductless	80%	81.1%	81.1%

FurnaceFlag = 1 if system replaced is a furnace (fossil fueled or electric), 0 if not.

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

For Early Replacement (1st 6 years) F_e_Exist = 3.14%[390]

For New Construction, Time of Sale and early replacement (remaining 10 years)

[386] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[387] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[388] Average nameplate efficiencies of all Early Replacement qualifying equipment in Ameren PY3-PY4.

[389] Values represent the weighted average AFUE baseline values reflecting the assumed shares of installed ASHP replacing given baseline technologies (e.g. ASHP/electric resistance or furnace/boiler) by fuel type. Assumed shares are based on Opinion Dynamics and Guidehouse analysis of 2018-2021 Ameren and ComEd HVAC (downstream) program tracking data. For further details, see '2018-2021 AIC Res HVAC Data ASHP Baseline TRM Update 2022-07-11.xls'.

[390] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

F_e_New = 1.88%[391]

3412 = Btu per kWh

%IncentiveElectric = % of total incentive paid by electric utility

= Actual

%IncentiveGas = % of total incentive paid by gas utility

= Actual

[391] New furnaces are required to have ECM fan motors installed. Comparing Eae to Ef for furnaces on the AHRI directory as above, indicates that Fe for new furnaces is on average 1.88%.

Non Fuel Switch Illustrative Examples

Time of Sale using ASHP baseline:

For example, an ASHP is installed in a single-family home in Marion with the following nameplate information: 15.2 SEER2, 11 EER2, 9 HSPF2; Cooling capacity: 34,800 Btuh; Heating capacity at 47°F: 33,000 Btuh; Heating capacity at 17°F: 21,200 Btuh with Quality Installation;

$\Delta kWh_{Non\ Fuel\ Switch}$ = ASHPSiteCoolingImpact + ASHPSiteHeatingImpact

ASHPSiteCoolingImpact = (((956 * 34,800)/1 * 1/(14.3 * (1 - 0.1))) – (956 * 34,800 * 1/(15.2 * (1 – 0)))) / 1,000

= 396 kWh

ASHPSiteHeatingImpact = (((1,270 * 33,000 * 1)/1 * (1/(7.5 * 0.91 * (1 – 0.1)) - 1/(9 * 0.91 * (1-0)))) / 1,000)

= 1,706 kWh

$\Delta kWh_{Non\ Fuel\ Switch}$ = 396 + 1706 = 2,102 kWh

Early Replacement:

For example, a 15.2 SEER2, 11 EER2, 9 HSPF2 Air Source Heat Pump with nameplate information as above replaces an existing working Air Source Heat Pump with unknown efficiency ratings in a single family home in Marion:

ΔkWH for remaining life of existing unit (1st 6 years):

ASHPSiteCoolingImpact = (((956 * 34,800)/1 * 1/(9.3 * (1 - 0.1))) – (956 * 34,800 * 1/(15.2 * (1 – 0)))) / 1,000

= 1,786 kWh

ASHPSiteHeatingImpact = (((1,270 * 33,000 * 1)/1 * (1/(5.54 * 0.91 * (1 – 0.1)) - 1/(9 * 0.91 * (1-0)))) / 1,000)

= 4,120 kWh

$\Delta kWh_{Non\ Fuel\ Switch}$ = 1,786 + 4,102 = 5,888 kWh

ΔkWH for remaining measure life (next 12 years):

= 2,102 kWh (as example above)

Fuel Switch Illustrative Examples

[for illustrative purposes, 50:50 Incentive is used for joint programs]

New construction using gas furnace and central AC baseline:

For example a 3-ton (Cooling capacity of 34,800Btuh and Heating capacity of 33,000 Btuh), 15.2 SEER2, 12.4 EER2, 9 HSPF2 ducted Air Source Heat Pump installed in single-family home in Marion with Quality Installation, in place of a 81,000 Btuh natural gas furnace and 3 ton Central AC unit:

SiteEnergySavings (MMBTUs) = GasHeatReplaced + FurnaceFanSavings – ASHPSiteHeatConsumed + ASHPSiteCoolingImpact

GasHeatReplaced = ((HeatLoad_Disp/DuctlessSave * 1/$AFUE_{base}$) / 1,000,000)

= (((1,270 * 33,000 * 1)/1 * 1/0.8) / 1,000,000)

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ((Capacity_cooling/DuctlessSave * (1/(EER2_base * (1 – $DeratingCool_{Base}$))) – (Capacity_cooling * 1/(EER2_ee * (1 – $DeratingCool_{Eff}$)))) / 1,000 * CF

Where:

EER2_base = Energy Efficiency Ratio 2 of baseline unit (kBtu/kWh). For early replacment measures, the actual EER2 rating where it is possible to measure or reasonably estimate should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time.[392] If unknown, assume default provided below. If unknown value is used, it should not be derated by age.

[392] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

Baseline/Existing Cooling System	EER2_base		
	Early Replacement (Remaining useful life of existing equipment)	Early Replacement (Remaining measure life)	Time of Sale or New Construction
Ducted Air Source Heat Pump – standard sized	7.4 EER2[393]	9.4 EER2[394]	
Ductless Air Source Heat Pump – standard sized	7.4 EER2	8.5 EER2	
Air Source Heat Pump – space constrained	7.4 EER2	7.8 EER2	
Central AC – standard sized	7.4 EER2	10.6 EER2	
Central AC – space constrained	7.4 EER2	9.2 EER2	
No central cooling	Make '1/EER2_exist' = 0 [395]	10.6 EER2[396]	
Unknown, installing ducted [397]	7.4 EER2	9.4 EER2	
Unknown, installing ductless	7.4 EER2	8.5 EER2	

EER2_ee = Energy Efficiency Ratio of efficient Air Source Heat Pump (kBtu/hr / kW)

= Actual. If unknown, assume 11 EER2.[398]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

= 72%[399]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during peak period)

= 46.6%[400]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[401]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

Use Multifamily if: Building meets utility's definition for multifamily and system serves single unit. For

[393] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018' Converted to EER2.
[394] Assumed consistent with the EER2 requirements in the Federal Standard for Southwest standards (in the absence of standards for Nothern states).
[395] If there is no central cooling in place but the incentive encourages installation of a new ASHP with cooling, the added cooling load should be subtracted from any heating benefit.
[396] Assumes that the decision to replace existing systems includes desire to add cooling.
[397] Program tracking data does not provide an EER2 value. These are estimated based on the other values in the table.
[398] ENERGY STAR v6.2 minimum specification.
[399] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[400] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[401] *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

residential sized systems serving 2 or more units, assume single family. For central systems use Volume 2 Commercial and Industrial Measures.

Time of Sale:

For example, a three ton, 15.2 SEER2, 11 EER2, 9 HSPF2 Air Source Heat Pump installed in single-family home in Marion with Quality Installation:

ΔkW_{SSP} = (36,000/1 * (1/(9.4 * (1-0.1)) – 1/(11 * (1-0)))) / 1,000 * 0.72

= 0.7075 kW

ΔkW_{PJM} = (36,000/1 * (1/(9.4 * (1-0.1)) – 1/(11 * (1-0)))) / 1,000 * 0.466

= 0.4579 kW

Early Replacement:

For example, a 3-ton, 15.2 SEER2, 11 EER2, 9 HSPF2 Air Source Heat Pump replaces an existing working Air Source Heat Pump with unknown efficiency ratings in single-family home in Marion with Quality Installation:

ΔkW_{SSP} for remaining life of existing unit (1st 6 years):

= (36,000/1 * (1/(7.5 * (1-0.1)) - 1/(11 * (1-0)))) / 1,000 * 0.72

= 1.48 kW

ΔkW_{SSP} for remaining measure life (next 10 years):

= (36,000/1 * (1/(9.4 * (1-0.1)) – 1/(11 * (1-0)))) / 1,000 * 0.72

= 0.7075 kW

ΔkW_{PJM} for remaining life of existing unit (1st 6 years):

= (36,000/1 * (1/(7.5 * (1-0.1)) - 1/(11 * (1-0)))) / 1,000 * 0.466

= 0.9602 kW

ΔkW_{PJM} for remaining measure life (next 10 years):

= (36,000/1 * (1/(9.4 * (1-0.1)) – 1/(11 * (1-0)))) / 1,000 * 0.466

= 0.4579 kW

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch ASHP projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure. For Early Replacement measures, the efficiency and Fe terms of the existing unit

should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 7 years for furnace, 8 years for boilers or GSHP, 16 years for electric resistance), and the efficiency and Fe terms for a new baseline unit should be used for the remaining years of the measure.

ΔTherms = [Heating Consumption Replaced]

= [(%FuelSwitch * HeatLoad_Disp/DuctlessSave * $1/AFUE_{base}$) / 100,000]

ΔkWh = [GasFurnaceFanSavings] - [ASHP heating consumption] + [Cooling savings]

= %FuelSwitch * [[FurnaceFlag * HeatLoad_Disp/DuctlessSave * $1/AFUE_{base}$ * F_e * 0.000293] - [(HeatLoad_Disp * (1/(HSPF2_ee * HSPF2_ClimateAdj * PD_Adj * (1 – $DeratingHeat_{Eff}$))))/1,000] + [((CoolingLoad/DuctlessSave * (1/(SEER2_base * (1 – $DeratingCool_{Base}$)))) – ((CoolingLoad * 1/(SEER2_ee * (1 – $DeratingCool_{Eff}$)))))/1,000]

REVIEW DEADLINE: 1/1/2028

5.3.2 Boiler Pipe Insulation

DESCRIPTION

This measure describes adding insulation to un-insulated boiler pipes in un-conditioned basements or crawlspaces.

This measure was developed to be applicable to the following program types: TOS, RNC, RF, DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is installing pipe wrap insulation to a length of boiler pipe.

DEFINITION OF BASELINE EQUIPMENT

The baseline is an un-insulated boiler pipe.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 11 years.[402]

Note a mid-life adjustment to account for replacement of HVAC equipment during the measure life should be applied after 9 years.[403] See section below for detail.

DEEMED MEASURE COST

The actual installation cost should be used if known. If unknown, the measure cost including material and installation is assumed to be $3 per linear foot.[404] For foam pipe insulation assume a measure cost of $0.56/ft for ½" insulation and $0.90/ft for ¾" insulation.[405]

$$\Delta Therm = (((1/R_{exist} - 1/R_{new}) * Ci_{nside} * L_{effective} * FLH_heat * \Delta T) / \eta Boiler)/100,000$$

Where:

[402] DEER 2014

[403] This is intentionally longer than the assumptions found in the early replacement measures as the application of this measure will occur in a variety of homes that will not be targeted for early replacement HVAC systems.

[404] Consistent with DEER 2008 Database Technology and Measure Cost Data.

[405] Review of website cost data for Homedepot.com, Lowes.com, and Menards.com for locations in Peoria, IL. Websites accessed 5/6/24.

R_{exist} = Pipe heat loss coefficient of uninsulated pipe (existing) [(hr-°F-ft^2)/Btu]

= Varies based on pipe size and material. See table below for values.

R_{new} = Pipe heat loss coefficient of insulated pipe (new) [(hr-°F-ft^2)/Btu]

= Actual (R_{exist} + R value of insulation[406])

C_{inside} = Inside circumference of the pipe [ft]

= Actual (0.5" pipe = 0.1427 ft, 0.75" pipe = 0.2055 ft); See table below for values.

$L_{effective}$ = Effective Length of pipe from boiler covered by pipe insulation (ft)[407]

= $L_{Horizontal} + \alpha L_{Vertical}$

= Actual; See table below for α values. If unknown, assume 3ft of vertical and remaining horizontal.

FLH_heat = Full load hours of heating

= Dependent on location:[408]

Climate Zone (City based upon)	FLH_heat
1 (Rockford)	1924
2 (Chicago)	1726
3 (Springfield)	1708
4 (Belleville)	1195
5 (Marion)	1270
Weighted Average[409]	
ComEd	1766
Ameren	1543
Statewide	1700

ΔT = Average temperature difference between circulated heated water and unconditioned space air temperature (°F) [410]

[406] Where possible it should be ensured that the R-value of the insulation is at the appropriate mean rating temperature (125F).
[407] In cases with zero wind, heat loss (and therefore) savings is larger from horiztonal pipe configurations than vertical pipe configurations due, perhaps to the way in which convective losses are handled. An analysis of the 3E PLUS tool by NAIMA (https://insulationinstitute.org/tools-resources/free-3e-plus/) yielded adjustment factors for horizontal to vertical loss and savings values. See DHW_PipeInsulationCalcs_062121.xlsx for details of the analysis and comparisons.
[408] Full load heating hours for heat pumps are provided for Rockford, Chicago and Springfield in the ENERGY STAR Calculator. Estimates for the other locations were calculated based on the FLH to Heating Degree Day (from NCDC) ratio. VEIC consider ENERGY STAR estimates to be high due to oversizing not being adequately addressed. Using average Illinois billing data (from Illinois Commerce Commission) VEIC estimated the average gas heating load and used this to estimate the average home heating output (using 83% average gas heat efficiency). Dividing this by a typical 36,000 Btu/hr ASHP gives an estimate of average ASHP FLH_heat of 1821 hours. We used the ratio of this value to the average of the locations using the ENERGY STAR data (1994 hours) to scale down the ENERGY STARr estimates. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of HDD60, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHheat values
[409] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.
[410] Assumes 160°F water temp for a boiler without reset control, 120°F for a boiler with reset control, and 50°F air temperature for pipes in unconditioned basements and the following average heating season outdoor temperatures as the air temperature in crawl spaces: Zone 1 – 33.1, Zone 2 – 34.4, Zone 3 – 37.7, Zone 4 – 40.0, Zone 5 – 39.8, Weighted Average – 35.3 (NCDC 1881-2010 Normals, average of monthly averages Nov – Apr for zones 1-3 and Nov-March for zones 4 and 5).

Pipes in unconditioned basement:

Outdoor reset controls	ΔT (°F)
Boiler without reset control	110
Boiler with reset control	70

Pipes in crawl space:

Climate Zone (City based upon)	ΔT (°F)	
	Boiler without reset control	Boiler with reset control
1 (Rockford)	127	87
2 (Chicago)	126	86
3 (Springfield)	122	82
4 (Belleville)	120	80
5 (Marion)	120	80
Weighted Average[411]	125	85

ηBoiler = Efficiency of boiler

= 0.819 [412]

Parameter assumptions for various pipe sizes and materials:

Type and Size	C_{Inside}[413] (I.D.*π/12) (ft)	Product of Overall Heat Transfer Coefficient and Pipe Area (UA) per foot[414] from bare pipe (BTU/hr·ft·°F)	Pipe Area per linear foot (ft^3)[415]	R_{exist} ((hr·ft·°F)/BTU)	Horizontal to Vertical Adjustment Factor (α)
½" Copper Pipe	0.1427	0.345	0.153	0.444	0.67
¾" Copper Pipe	0.2055	0.417	0.217	0.521	0.72
½" PEX	0.1270	0.438	0.145	0.332	0.73
¾" PEX	0.1783	0.545	0.204	0.374	0.77

For example, insulating 10 feet of 0.75" copper pipe (4ft vertical and 6 ft horizontal) with R-3 insulation in a crawl space of a Marion home with a boiler without reset control:

ΔTherm = (((1/0.521– 1/3.521) * 0.2055 * (6 + 4*0.72) * 110 * 1270) / 0.819) / 100,067

= 5.09 therms

Mid-Life adjustment

In order to account for the likely replacement of existing heating equipment during the lifetime of this measure, a mid-life adjustment should be applied. To calculate the adjustment, re-calculate the savings above using the

[411] Weighted based on number of occupied residential housing units in each zone.
[412] Average efficiency of boiler units found in Ameren PY3-PY4 data.
[413] See: https://energy-models.com/pipe-sizing-charts-tables (last accessed 5/7/21) for copper pipe sizes and https://www.garagesanctum.com/size-chart/pex-tubing-size-chart/ (last accessed 5/7/21) for PEX pipe sizes.
[414] Laboratory measured values from Hoeschele and Weitzel (2012), Figure 1.
[415] Calculated using the average pipe thickness (I.D. + O.D.)*0.5.

following new baseline system efficiency assumptions:

Efficiency Assumption	System Type	New Baseline Efficiency
ηHeat	Boiler	84% AFUE

This reduced annual savings should be applied following the assumed remaining useful life of the existing equipment, estimate to be 13 years.[416] Note if the existing equipment efficiency is greater than the new baseline efficiency listed above, do not apply a mid-life adjustment.

REVIEW DEADLINE: 1/1/2027

[416] This is intentionally longer than the assumption found in the early replacement measures as the application of this measure will occur in a variety of homes and will not be targeting those homes appropriate for early replacement HVAC systems.

5.3.3 Central Air Conditioning

DESCRIPTION

This measure characterizes:

a) Time of Sale:
   a. The installation of a new residential sized (<= 65,000 Btu/hr) Central Air Conditioning ducted split system meeting specifications determined by the program. This could relate to the replacement of an existing unit at the end of its useful life, or the installation of a new system in a new home.

b) Early Replacement:

Early Replacement determination will be based on meeting the following conditions:

- The existing unit is operational when replaced, or
- The existing unit requires minor repairs (<$190 per ton).[417]
- All other conditions will be considered Time of Sale.

The Baseline SEER2 of the existing Central Air Conditioning unit replaced:

- If the SEER of the existing unit is known use the actual SEER (converted to SEER2) value of the unit replaced.
- If the SEER of the existing unit is unknown, use assumptions in variable list below (SEER2_exist).
- If the operational status or repair cost of the existing unit is unknown, use time of sale assumptions.

A weighted average early replacement rate is provided when the actual baseline early replacement rate is unknown.[418]

Deemed Early Replacement Rates for CAC Units in Combined System Replacement (CSR) Projects

Replacement Scenario for the CAC Unit	Deemed Early Replacement Rate
Early Replacement Rate for participants when a CAC unit when the CAC unit is the Primary unit in a CSR project	14%
Early Replacement Rate for participants when a CAC unit when the CAC unit is the Secondary unit in a CSR project	40%

Note: it is not appropriate to claim additional ECM fan savings (from 5.3.5 Furnace Blower Motor) due to installing new CAC units with an ECM, since the SEER2/EER2 ratings already account for this electrical load.

Quality Installation:

Additional savings are attributed to the Quality Installation (QI) of the system. QI programs should follow industry standards such as those described in ENERGY STAR Verified HVAC Installation Program (ESVI), ANSI ACCA QI5 and QI9vp. This must include considerations of system design (including sizing, matching, ventilation calculations) and

[417] The Technical Advisory Committee agreed that if the cost of repair is less than 20% of the new baseline replacement cost it can be considered early replacement. Note the non-inflated cost is used as this would be a cost consideration in the program year.

[418] Based upon research from "Home Energy Efficiency Rebate Program GPY2 Evaluation Report" which outlines early replacement rates for both primary and secondary central air cooling (CAC) and residential furnaces. The unit (furnace or CAC unit) that initially caused the customer to contact a trade ally is defined as the "primary unit". The furnace or CAC unit that was also replaced but did not initially prompt the customer to contact a trade ally is defined as the "secondary unit". This evaluation used different criteria for early replacement due to the availability of data after the fact; cost of any repairs < $550 and age of unit < 20 years. Report presented to Nicor Gas Company February 27, 2014.

equipment installation (including static pressure, airflow, refrigerant charge) and may also consider distribution.

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment is assumed to be a ducted split central air conditioning unit meeting specifications determined by the program. For reference, the minimum Consortium for Energy Efficiency (CEE) efficiency level standards are provided below[419]:

- Split system central air conditioners – 17 SEER2 and 12.0 EER2
- Single package central air conditioners – 16 SEER2 and 11.5 EER2
- Space constrained units – 13.4 SEER2[420]

The measure characterization recommends sourcing the efficiency specifications from the actually installed equipment. If those values are not known, the default equipment efficiency recommendations are conservatively based on Consortium for Energy Efficiency (CEE) specifications.

The following conversion factors are recommended for use if the efficient equipment is not rated under the new testing procedure:[421]

SEER2 = SEER * X

EER2 = EER * X

Where:

X	SEER	EER
Ducted	0.95	0.95
Packaged	0.95	0.95

DEFINITION OF BASELINE EQUIPMENT

The baseline for the Time of Sale measure is based on the current Federal Standard efficiency level[422]:

- Standard sized Split system air conditioners – 13.4 SEER2
- Standard sized Single-package air conditioners – 13.4 SEER2

[419] Consortium for Energy Efficiency (CEE) Residential HVAC Specifications, effective January 1, 2026, are in terms of an updated metric, depicted as SEER2 and EER2. The updated test method as well as the updated Consortium for Energy Efficiency (CEE) specifications mimic the updated federal appliance standards. An equivalent stringency of these new standards for split system air conditioners are 16 SEER and 13 EER and for single-package air conditioners are 16 SEER and EER 12, as detailed in: Consortium for Energy Efficiency (CEE) Residential HVAC Specifications, Estimated Appendix M1 Equivalents, January 15 2021

[420] The Consortium for Energy Efficiency (CEE) specification does not provide an efficiency level for space constrained products but this is a proposed level for this product type that the marketplace has developed solutions to meet.

[421] Consortium for Energy Efficiency (CEE), Testing, Testing, M1, 2, 3, Transitioning to New Federal Minimum Standards, CEE Summer Program Meeting, June 10, 2022.

[422] The 2023 federal standards (10 CFR 430.32(c)(5)) are in terms of an updated metric, depicted as SEER2 and manufacturers must certify their products meet the standard according to the new test procedure and new metrics. The updated test method as well as the updated energy conservation standards were negotiated under the appliance standards and rulemaking federal advisory committee (ASRAC) in accordance with the Federal Advisory Committee Act (FACA) and the negotiated rulemaking act. An equivalent stringency of these new standards for split system air conditioners are 14 SEER and for single-package air conditioners are 14 SEER, as detailed in: Federal Code of Regulations, Energy Conservation Program: Energy Conservations Standards for residential Central Air Conditioners and Heat Pumps; Confirmation of effective date and compliance date for direct final rule, May 26, 2017, Docket: EERE-2014-BT-STD-0048 (https://www.regulations.gov/document/EERE-2014-BT-STD-0048-0200)

- Space constrained air conditioners – 11.7 SEER2
- Room AC for mobile homes – 9.8 CEER

Note, the space constrained product baseline should only be used when the efficient unit is classified as space constrained. It is assumed that 'Quality Installation' did not occur.

For mobile homes, replacing central AC presents a series of challenges, not least due to structural limitations. It is assumed that in the absence of program support, units would not be replaced with a new central AC unit but instead be replaced with multiple room AC units.

The baseline for the early replacement measure is the efficiency of the existing equipment for the assumed remaining useful life of the unit and the new baseline as defined above for the remainder of the measure life.[423] Consistent with TRM Volume 1 Section 2.3.1 for midstream programs or other cases where the existing condition is unknown, it may be appropriate to apply a deemed percent split of Time of Sale and Early Replacement assumptions based on evaluation results

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 18 years.[424]

Remaining life of existing equipment is assumed to be 6 years.[425]

DEEMED MEASURE COST

Time of sale (non-mobile homes): The incremental capital cost for this measure is dependent on capacity. Assumed incremental costs are provided below:[426]

Capacity Range	Efficient Cost	Baseline Cost per Ton	Incremental Cost
< 2 tons	$2,591 / ton + ($100 * (SEER2 - 15.2))	$2,340	$251 / ton + ($100 * (SEER2 - 15.2))
≥2 tons - < 3 tons	$2,104 / ton + ($100 * (SEER2 - 15.2))	$1,900	$204 / ton + ($100 * (SEER2 - 15.2))
≥ 3 tons	$1,661 / ton + ($100 * (SEER2 - 15.2))	$1,500	$161 / ton + ($100 * (SEER2 - 15.2))

Time of sale (mobile homes):

For mobile homes, this measure assumes a baseline of three 8,500 BTU/hr room AC units purchased via the secondary market and assumed to cost $50 each – for a total of $150. This should be compared to a typical retail cost for an efficient 3-ton unit from table above.

An additional $150 every 6 years should be included to account for the replacement of the secondhand room AC units.

Early replacement: The full install cost for this measure is the actual cost of removing the existing unit and installing the new one. If this is unknown, assume defaults from table above.

Assumed deferred cost (after 6 years) of replacing existing equipment with new baseline unit is presented in the

[423] Baseline SEER and EER should be updated when new minimum federal standards become effective.
[424] Measure Life Report, Residential and Commercial/Industrial Lighting and HVAC Measures, GDS Associates, June 2007.
[425] Assumed to be one third of effective useful life.
[426] In 2025, a working group was created to update costs for residential HVAC equipment. Heat Pump and Central Air Conditioning costs are based upon Ameren program data. Furnace and Boiler costs are based on Ameren, Nicor, People's Gas, and North Shore Gas program data. Baseline costs have been determined using ratios from Updated Buildings Sector Appliance and Equipment Costs and Efficiencies by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration, March 2023. See file "HVAC Costs – 071825_VEIC.xlsx" for more details.

table below for non-mobile homes and is assumed to be $150 for mobile homes. This cost should be discounted to present value using the nominal societal discount rate.

Capacity Range	Deferred Baseline Cost per Ton[427]
< 2 tons	$2,679
≥ 2 to < 3 tons	$2,175
≥ 3 tons	$1,717

Quality Installation: The additional design and installation work associated with quality installation has been estimated to cost an additional $150.[428]

LOADSHAPE

Loadshape R08 - Residential Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)
= 68%[429]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)
= 46.6%[430]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Time of sale (non-mobile homes):

$$\Delta kWH = (FLHcool * Capacity * (1/(SEER2base * (1 - DeratingCool_{Base})) - 1/(SEER2ee * (1 - DeratingCool_{Eff}))))/1000$$

Time of sale (mobile homes):

$$\Delta kWH = kWhBaseRAC - kWhEffCAC$$

$$kWhBaseRAC = (\#RACUnits * FLHcool * CapacityRAC * (1/(EERbase/1.01)))/1,000$$

$$kWhEffCAC = (FLHcool * Capacity * (1/(SEER2ee (1 - DeratingCool_{Eff}))))/1,000$$

Early replacement:[431]

[427] All baseline replacement costs include inflation rate of 2.28%.
[428] Based on data provided by MidAmerican in April 2018 summarizing survey results from 11 HVAC suppliers in Iowa.
[429] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[430] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[431] The two equations are provided to show how savings are determined during the initial phase of the measure (existing to efficient) and the remaining phase (new baseline to efficient). In practice, the screening tools used may either require a First

ΔkWH for remaining life of existing unit (1st 6 years):

=(FLHcool * Capacity * (1/(SEER2exist * (1 – $DeratingCool_{Base}$)) - 1/(SEER2ee * (1 – $DeratingCool_{Eff}$))))/1,000

ΔkWH for remaining measure life (next 12 years) – non mobile-homes:

= (FLHcool * Capacity * (1/(SEER2base * (1 – $DeratingCool_{Base}$)) - 1/(SEER2ee * (1 – $DeratingCool_{Eff}$))))/1,000

ΔkWH for remaining measure life (next 12 years) – mobile-homes:

= kWhBaseRAC – kWhEffCAC

kWhBaseRAC = (#RACUnits * FLHcool * CapacityRAC * (1/(EERbase/1.01)))/1,000

kWhEffCAC = (FLHcool * Capacity * (1/(SEER2ee * (1 – $DeratingCool_{Eff}$))))/1,000

Where:

FLHcool = Full load cooling hours

= dependent on location and building type:[432]

Climate Zone (City based upon)	FLHcool (single family)	FLHcool (multifamily)	FLH_cooling (weatherized multifamily) [433]
1 (Rockford)	547	499	320
2 (Chicago)	709	629	403
3 (Springfield)	779	707	453
4 (Belleville)	1,082	982	630
5 (Marion)	956	868	557
Weighted Average[434]			
ComEd	676	603	386
Ameren	875	791	507
Statewide	731	655	420

Use Multifamily if the Building meets the utility's definition for multifamily and system serves single unit. For residential sized systems serving 2 or more units, assume single family hours. For central systems use Volume 2 Commercial and Industrial Measures.

Capacity = Output capacity of new equipment in Btu/hr (note 1 ton = 12,000Btu/hr)

= Use actual when program delivery allows size of AC unit to be known. If unknown, use

Year savings (using the first equation) and then a "number of years to adjustment" and "savings adjustment" input which would be the (new base to efficient savings)/(existing to efficient savings).

[432] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[433] *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015. The multifamily units within this study had undergone significant shell improvements (air sealing and insulation) and therefore this set of assumptions is only appropriate for units that have recently participated in a weatherization or other shell program. Note that the FLHcool where recalculated based on existing efficiencies consistent with the TRM rather than from the metering study. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[434] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

table:

Housing Type[435]	Capacity (Btu/hr)
Single Family Non-Low Income	37,200
Single Family Low Income	31,200
Multi-family Non-Low Income	28,800
Multi-family Low income	30,000
Mobile homes[436]	24,000
Unknown	33,600

SEER2base = Seasonal Energy Efficiency Ratio of baseline unit (kBtu/kWh)

= 13.4 SEER2 for standard sized units or 11.7 SEER2 for space constrained units[437]

SEER2exist = Seasonal Energy Efficiency Ratio 2 of existing unit (kBtu/kWh)

= Use actual SEER2 rating where it is possible to measure or reasonably estimate. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[438] or, if unknown, assume 9.2 SEER2.[439] If unknown value is used, it should not be derated by age.

SEER2ee = Rated Seasonal Energy Efficiency Ratio 2 of CEE unit (kBtu/kWh)

= Actual, or 17 SEER2 (17.9 SEER) if unknown.

$DeratingCool_{Eff}$ = Efficent Central Air Conditioner Cooling derating

= 0% if Quality Installation is performed

= 10% if Quality Installation is not performed or unknown[440]

$DeratingCool_{Base}$ = Baseline Central Air Conditioner Cooling derating

= 10%

#RACUnits = Number of Room AC units assumed to have been installed in mobile home instead of a replacement CAC unit

= Actual, if unknown assume 3

CapacityRAC = Capacity of assumed Room AC unit

[435] All values except Mobile Home data based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential baseline Study Results", Oct 31 2024.

[436] Mobile home capacity based on ENERGY STAR's Manufactured Home Cooling Equipment Sizing Guidelines which vary by climate zone and home size. The average size of a mobile home in the East North Central region (1,120 square feet) from the 2015 RECS data is used to calculated appropriate size.

[437] Based on Minimum Federal Standard.

[438] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[439] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants, assumption provided for 2020; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018' Converted to SEER2.

[440] Based on Cadmus assumption provided in preparation of the 2014 Interstate Power and Light TRM based upon proper refrigerant charge, evaporator airflow, and unit sizing, Appears conservative in comparison to ENERGY STAR statements (see 'Sponsoring an ENERGY STAR Verified HVAC Installation (ESVI) Program').

= Actual, if unknown assume 8500 Btu/hr[441]

CEERbase = Efficiency of baseline Room AC unit, assumed to be purchased through the secondary market

= Actual (if existing unit has EER rating, convert to CEER by dividing by 1.01[442]).

If unknown assume 9.8 [443]

Time of sale non mobile-home example: a 3 ton unit with SEER2 rating of 17, EER2 rating of 12.5 in unknown location without Quality Install:

ΔkWH = (731 * 36,000 * (1/(13.4 * (1-0.1)) – 1 / (17 * (1-0.1)))) / 1,000

= 462 kWh

Time of sale example: a 3-ton unit with SEER2 rating of 17, EER2 rating of 12.5 in unknown location with Quality Install:

ΔkWH = (731 * 36,000 * (1/(13.4 * (1-0.1)) – 1 / (17 * (1-0)))) / 1,000

= 634 kWh

Time of sale mobile-home example: a 3-ton unit with SEER2 rating of 17, EER2 rating of 12.5 is installed with Quality Install in a mobile home in Belleville, in place of 3 Room AC units:

ΔkWH = kWhBaseRAC – kWhEffCAC

kWhBaseRAC = (3 * 1,082 * 8,500 * (1/(7.7/1.01)))/1,000

= 3,619 kWh

kWhEffCAC = (1,082 * 36,000 * (1/(17 * (1 – 0))))/1,000

= 2,291 kWh

ΔkWH = 3,619 – 2,291

= 1,328 kWh

Early replacement example: a 3-ton unit, with SEER2 rating of 17, EER2 rating of 12.5 replaces an existing unit in unknown location with quality installation:

ΔkWH(for first 6 years) = (731 * 36,000 * (1/(9.2 * (1-0.1)) - 1/(17 * (1-0))))/1,000

= 1,630 kWh

ΔkWH(for next 12 years) = (731 * 36,000 * (1/(13.4 * (1-0.1)) - 1/(17 * (1-0))))/1,000

= 634 kWh

Therefore, savings adjustment of 39% (634/1,630) after 6 years.

[441] Based on maximum capacity average from the RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008

[442] This factor is used to appropriately compare with the new CEER rating which includes standby and off power consumption. Version 3.0 of the ENERGY STAR specification provided equivalent EER and CEER ratings and for the most popular size band the EER rating is approximately 1% higher than the CEER. See 'ENERGY STAR Version 3.0 Room Air Conditioners Program Requirements'.

[443] This is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) prior to 6/1/2014.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Time of sale (non mobile-homes):

ΔkW = (Capacity * (1/(EER2base * (1 – DeratingCool$_{Base}$)) - 1/(EER2ee * (1 – DeratingCool$_{Eff}$))))/1,000 * CF

Time of sale (mobile-homes):

ΔkW = (kWBaseRAC – kWEffCAC) * CF

kWBaseRAC = (#RACUnits * CapacityRAC * (1/(CEERbase * 1.01)))/1,000

kWEffCAC = (Capacity * (1/(EER2ee (1 – DeratingCool$_{Eff}$))))/1,000

Early replacement:[444]

ΔkW for remaining life of existing unit (1st 6 years):

= (Capacity * (1/(EER2exist * (1 – DeratingCool$_{Base}$)) - 1/(EER2ee* (1 – DeratingCool$_{Eff}$))))/1,000 * CF

ΔkW for remaining measure life (next 12 years) – non mobile-homes:

= (Capacity * (1/(EER2base * (1 – DeratingCool$_{Base}$)) - 1/(EER2ee* (1 – DeratingCool$_{Eff}$))))/1,000 * CF

ΔkW for remaining measure life (next 12 years) –mobile-homes:

= (kWBaseRAC – kWEffCAC) * CF

kWBaseRAC = (#RACUnits * CapacityRAC * (1/(CEERbase * 1.01))/1,000

kWEffCAC = (Capacity * (1/(EER2ee (1 – DeratingCool$_{Eff}$))))/1,000

Where:

EER2base = EER2 Efficiency of baseline unit

= 10.6 EER2 for standard sized units[445]

= 9.2 EER2 for space constrained units

EER2exist = EER2 Efficiency of existing unit

= Use actual EER2 rating where it is possible to measure or reasonably estimate. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time.[446] If unknown, assume 7.4 EER2.[447] If unknown value is used, it should not be derated by age.

EER2ee = EER2 Efficiency of CEE unit

[444] The two equations are provided to show how savings are determined during the initial phase of the measure (existing to efficient) and the remaining phase (new baseline to efficient). In practice, the screening tools used may either require a First Year savings (using the first equation) and then a "number of years to adjustment" and "savings adjustment" input which would be the (new base to efficient savings)/(existing to efficient savings).

[445] The federal Standard does not currently include an EER2 component. The value provided is based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Converted to EER2.

[446] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[447] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Converted to EER2.

= Actual installed or 12 EER2 if unknown

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)

= 68%[448]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during peak period)

= 46.6%[449]

Time of sale non mobile-home example: a 3 ton unit with EER2 rating of 12 with Quality Install:

ΔkW_{SSP} = (36,000 * (1/(10.6 * (1-0.1)) – 1/(12 * (1-0)))) / 1,000 * 0.68

= 0.5260 kW

ΔkW_{PJM} = (36,000 * (1/(10.6 * (1-0.1)) – 1/(12 * (1-0)))) / 1,000 * 0.466

= 0.3605 kW

Time of sale mobile-home example: a 3 ton unit with EER2 rating of 12 is installed with Quality Install in a mobile home, in place of 3 Room AC units:

ΔkW = (kWBaseRAC – kWEffCAC) * CF

kWBaseRAC = (3 * 8,500 * (1/(7.7/1.01)))/1,000

= 3.3448kW

kWEffCAC = (36,000 * (1/(12 * (1 – 0))))/1,000

= 3.0000kW

ΔkW_{SSP} = (3.3448 – 3.0000) * 0.68

= 0.2345 kW

ΔkW_{PJM} = (3.3448 – 3.0000) * 0.466

= 0.1607 kW

Early replacement example: a 3 ton unit with EER2 rating of 12 replaces an existing unit with Quality Install:

ΔkW_{SSP} (for first 6 years) = (36,000 * (1/(7.4 * (1-0.1)) – 1/(12 * (1-0)))) / 1,000 * 0.68

= 1.636 kW

ΔkW_{SSP} (for next 12 years) = (36,000 * (1/(10.1 * (1-0.1)) – 1/(12 * (1-0)))) / 1,000 * 0.68

= 0.653 kW

ΔkW_{PJM} (for first 6 years) = (36,000 * (1/(7.4 * (1-0.1)) – 1/(12 * (1-0)))) / 1,000 * 0.466

= 1.121 kW

ΔkW_{PJM} (for next 12 years) = (36,000 * (1/(10.1 * (1-0.1)) – 1/(12 * (1-0)))) / 1,000 * 0.466

= 0.448 kW

5.3.4 Duct Insulation and Sealing

DESCRIPTION

This measure describes evaluating the savings associated with adding duct insulation or performing duct sealing using mastic sealant, metal tape, or injection of UL certified and low VOC for sealant to the distribution system of homes with either central air conditioning or a ducted heating system.

Three methodologies for estimating the savings associate from sealing the ducts are provided, one of which can also be used to estimate duct insulation savings. The first preferred method requires the use of a blower door, the second method requires a pressurized duct test, and the third requires careful inspection of the duct work.

1. **Modified Blower Door Subtraction** – this technique is described in detail on the Energy Conservatory website. See 'The Energy Conservatory_Blower-Door-Subtraction-Method.pdf'.
2. **Pressurized Duct Test** – this technique includes direct measurement of air leaks in the duct system.
3. **Evaluation of Distribution Efficiency** – this methodology can be used to estimate duct insulation or duct sealing savings, and requires the evaluation of three duct characteristics below, and use of the Building Performance Institutes 'Distribution Efficiency Look-Up Table'[450].
    a. Percentage of duct work found within the conditioned space
    b. Duct leakage evaluation
    c. Duct insulation evaluation

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

For duct insulation and sealing of central systems in multifamily buildings, use Volume 2 Commercial and Industrial Measures.

DEFINITION OF EFFICIENT EQUIPMENT

For duct sealing, the efficient condition is sealed duct work throughout the unconditioned or semi-conditioned space in the home. A non-conditioned space is defined as a space outside of the thermal envelope of the building that is not intentionally heated for occupancy (crawl space, roof attic, etc.). A semi-conditioned space is defined as a space within the thermal envelop that is not intentionally heated for occupancy (unfinished basement).[451]

For duct insulation, the efficient condition is ductwork insulated with a minimum of R-4 insulation in an unconditioned or semi-conditioned space in the home.

DEFINITION OF BASELINE EQUIPMENT

For duct sealing, the existing baseline condition is leaky duct work within the unconditioned or semi-conditioned space in the home.

For duct insulation, the baseline condition is un-insulated ductwork that passes through an unconditioned or semi-conditioned space in the home.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of this measure is 20 years.[452]

Note: a mid-life adjustment to account for replacement of HVAC equipment during the measure life should be

[450]Building Performance Institute, Distribution Efficiency Look-up Tables.
https://www.bpi.org/sites/default/files/Guidance%20on%20Estimating%20Distribution%20Efficiency.pdf
[451] Definition matches Regain factor discussed in Home Energy Services Impact Evaluation, prepared for the Massachusetts Residential Retrofit and Low Income Program Area Evaluation, Cadmus Group, Inc., August 2012
[452] Measure Life Report, Residential and Commercial/Industrial Lighting and HVAC Measures, GDS Associates, June 2007.

applied after 10 years.[453] See section below for detail.

DEEMED MEASURE COST

The actual duct sealing or insulating measure cost should be used.

LOADSHAPE

Loadshape R08 - Residential Cooling

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling (Shell Measures)

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[454]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[455]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

For Methodology 1: Modified Blower Door Subtraction, follow steps (a) through (c)

For Methodology 2: Pressurized Duct Test, follow step (c)

a) Determine Duct Leakage rate before and after performing duct sealing:
Duct Leakage ($CFM50_{DL}$) = ($CFM50_{Whole\ House}$ – $CFM50_{Envelope\ Only}$) * SCF

Where:

$CFM50_{Whole\ House}$ = Standard Blower Door test result finding Cubic Feet per Minute at 50 Pascal pressure differential

$CFM50_{Envelope\ Only}$ = Blower Door test result finding Cubic Feet per Minute at 50 Pascal pressure differential with all supply and return registers sealed.

SCF = Subtraction Correction Factor to account for underestimation of duct leakage due to connections between the duct system and the home. Determined by measuring pressure in duct system with registers sealed and using look up table provided by Energy Conservatory.

b) Calculate duct leakage reduction, convert to $CFM25_{DL}$ and factor in Supply and Return Loss Factors

[453] This is intentionally longer than the assumptions found in the early replacement measures as the application of this measure will occur in a variety of homes that will not be targeted for early replacement HVAC systems.
[454] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[455] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Duct Leakage Reduction ($\Delta CFM25_{DL}$) = (Pre $CFM50_{DL}$ – Post $CFM50_{DL}$) * 0.64 * (SLF + RLF)

Where:

0.64 = Converts CFM50 to CFM25[456]

SLF = Supply Loss Factor

= % leaks sealed located in Supply ducts * 1 [457]

Default = 0.5[458]

RLF = Return Loss Factor

= % leaks sealed located in Return ducts * 0.5[459]

Default = 0.25[460]

c) Calculate Electric Energy Savings:

ΔkWh = $\Delta kWh_{cooling} + \Delta kWh_{heatingElectric} + \Delta kWh_{Fan}$

$\Delta kWh_{cooling}$ = $((\Delta CFM25_{DL}/ ((OutputCapacityCool/12,000) * 400)) * FLHcool * OutputCapacityCool * TRFcool * \%Cool) / 1,000 / \eta Cool$

$\Delta kWh_{heatingElectric}$ = $((\Delta CFM25_{DL} /((OutputCapacityHeat/12,000) * 400)) * FLHheat * OutputCapacityHeat * TRFheat * \%ElectricHeat) / \eta Heat / 3412$

ΔkWh_{Fan} If fossil fueled furnace: = (ΔTherms * F_e * 29.3)

If electric furnace: = ΔkWh_heating * F_e

Where:

$\Delta CFM25_{DL}$ = Duct leakage reduction in CFM25

= For Methodology 1: Modified Blower Door Subtraction,calculated above

= For Methodology 2: Pressurized Duct Test, use actual

OutputCapacityCool = Output capacity of Air Cooling system (Btu/hr)

= Actual

12,000 = Converts Btu/H capacity to tons

[456] 25 Pascals is the standard assumption for typical pressures experienced in the duct system under normal operating conditions. To convert CFM50 to CFM25 you multiply by 0.64 (inverse of the "Can't Reach Fifty" factor for CFM25; see Energy Conservatory Blower Door Manual).

[457] Assumes that for each percent of supply air loss there is one percent annual energy penalty. This assumes supply side leaks are direct losses to the outside and are not recaptured back to the house. This could be adjusted downward to reflect regain of usable energy to the house from duct leaks. For example, during the winter some of the energy lost from supply leaks in a crawlspace will probably be regained back to the house (sometimes 1/2 or more may be regained). More information provided in "Appendix E Estimating HVAC System Loss From Duct Airtightness Measurements" from Energy Conservatory 'Minneapolis Duct Blaster Operation Manual'.

[458] Assumes 50% of leaks are in supply ducts.

[459] Assumes that for each percent of return air loss there is a half percent annual energy penalty. Note that this assumes that return leaks contribute less to energy losses than do supply leaks. This value could be adjusted upward if there was reason to suspect that the return leaks contribute significantly more energy loss than "average" (e.g. pulling return air from a super heated attic), or can be adjusted downward to represent significantly less energy loss (e.g. pulling return air from a moderate temperature crawl space) . More information provided in "Appendix E Estimating HVAC System Loss From Duct Airtightness Measurements" from Energy Conservatory 'Minneapolis Duct Blaster Operation Manual'.

[460] Assumes 50% of leaks are in return ducts.

400 = Converts capacity in tons to CFM (400CFM / ton)[461]

FLHcool = Full load cooling hours

= Dependent on location as below:[462]

Climate Zone (City based upon)	FLHcool Single Family	FLHcool Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1,082	982
5 (Marion)	956	868
Weighted Average[463]		
ComEd	676	603
Ameren	875	791
Statewide	731	655

Use Multifamily if: Building meets utility's definition for multifamily and system serves single unit. For residential sized systems serving 2 or more units, assume single family hours. For central systems use Volume 2 Commercial and Industrial Measures.

TRFcool = Thermal Regain Factor for cooling by space type

= 1.0 for Unconditioned Spaces

= 0.4 for Semi-Conditioned Spaces[464]

%Cool = Percent of homes that have cooling

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[465]	98.9%	96.5%	99.8%	98.7%	98.6%

1000 = Converts Btu to kBtu

ηCool = Efficiency (SEER2) of Air Conditioning equipment (kBtu/kWh) * $DistEff_{base}$

$DistEff_{base}$ = Distribution Efficiency of base condition

= Actual where it is possible to measure or reasonably estimate. If unknown

[461] This conversion is an industry rule of thumb; e.g. see 'Why 400 CFM per ton.pdf'.

[462] Based on Full Load Hours from ENERGY STAR with adjustments made in a Navigant Evaluation, other cities were scaled using those results and CDD. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[463] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[464] Thermal regain (i.e. the potential for conditioned air escaping from ducts not being lost to the atmosphere) for residential pipe insulation measures is discussed in Home Energy Services Impact Evaluation, prepared for the Massachusetts Residential Retrofit and Low Income Program Area Evaluation, Cadmus Group, Inc., August 2012.

[465] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

assume 0.85[466]

= Actual. If unknown assume the following:[467]

Age of Equipment	SEER2 Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
After 2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3
Unknown (for use in program evaluation only)[468]		
Single Family Non-IQ		10.5
Single Family IQ		10.5
Multi Family Non-IQ		10.6
Multi Family IQ		10.5
Unknown		10.5

ΔTherms = Therm savings as calculated in Fossil Fuel Savings

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[469]

29.3 = kWh per therm

[466] Based on Building Performance Institute Inc., "Duct Efficiency Tables".

[467] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

[468] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[469] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

For example, duct sealing in unconditioned space a single family house in Springfield with a 36,000 Btu/H, SEER 11 central air conditioning with 85% estimated distribution efficiency, an 80% AFUE, 105,000 Btu/H natural gas furnace and the following blower door test results:

Before: $CFM50_{Whole\ House}$ = 4800 CFM50

$CFM50_{Envelope\ Only}$ = 4500 CFM50

House to duct pressure of 45 Pascals. = 1.29 SCF (Energy Conservatory look up table)

After: $CFM50_{Whole\ House}$ = 4600 CFM50

$CFM50_{Envelope\ Only}$ = 4500 CFM50

House to duct pressure of 43 Pascals = 1.39 SCF (Energy Conservatory look up table)

Duct Leakage:

$CFM50_{DL\ before}$ = (4800 – 4500) * 1.29

= 387 CFM

$CFM50_{DL\ after}$ = (4600 – 4500) * 1.39

= 139 CFM

Duct Leakage reduction at CFM25:

$\Delta CFM25_{DL}$ = (387 – 139) * 0.64 * (0.5 + 0.25)

= 119 CFM25

Energy Savings:

$\Delta kWh_{cooling}$ = [((119 / ((36,000/12,000) * 400)) * 779 * 36,000 * 1) / 1000 / (11 * 0.85)] + (179 * 0.0314 * 29.3)

= 297 + 165

= 462 kWh

Heating savings for homes with electric heat:

$\Delta kWh_{heatingElectric}$ = (($\Delta CFM25_{DL}$ /((OutputCapacityHeat/12,000) * 400)) * FLHheat * OutputCapacityHeat * TRFheat *%ElectricHeat) / ηHeat / 3412

Where:

OutputCapacityHeat = Heating output capacity (Btu/hr) of electric heat

=Actual

FLHheat = Full load heating hours

= Dependent on location as below:[470]

Climate Zone (City based upon)	FLH_heat
1 (Rockford)	1924
2 (Chicago)	1726
3 (Springfield)	1708
4 (Belleville)	1195
5 (Marion/Murphysboro)	1270

[470] Heating EFLH based on ENERGY STAR EFLH for Rockford, Chicago, and Springfield and on NCDC/NOAA HDD for the other two cities. In all cases, the hours were adjusted based on average natural gas heating consumption in IL.

Climate Zone (City based upon)	FLH_heat
Weighted Average[471]	
ComEd	1766
Ameren	1547
Statewide	1700

TRFheat = Thermal Regain Factor for heating by space type

= 0.40 for Semi-Conditioned Spaces

= 1.0 for Unconditioned Spaces[472]

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= 0 % for Natural Gas

= If unknown[473], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[474]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

ηHeat = Efficiency in COP of Heating equipment * $DistEff_{base}$

$DistEff_{base}$ = Distribution Efficiency of base condition

= Actual where it is possible to measure or reasonably estimate. If unknown assume 0.85[475]

[471] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[472] Thermal regain (i.e. the potential for conditioned air escaping from ducts not being lost to the atmosphere) for residential pipe insulation measures is discussed in Home Energy Services Impact Evaluation, prepared for the Massachusetts Residential Retrofit and Low Income Program Area Evaluation, Cadmus Group, Inc., August 2012.

[473] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[474] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[475] Based on Building Performance Institute Inc., "Duct Efficiency Tables".

= Actual. If not available use:[476]

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) = (HSPF2/3.412)*0.85
Heat Pump (if age unknown, assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown (for use in program evaluation only)[477]	N/A	N/A	1.32

3412 = Converts Btu to kWh

For example, duct sealing in unconditioned space in a 36,000 Btu/H 2.5 COP heat pump heated single family house in Springfield with the blower door results described above:

$\Delta kWh_{heating}$ = ((119 / ((36,000/12,000) * 400)) * 1,708 * 36,000 * 1 * 1) / 2.5 / 3,412

= 715 kWh

Methodology 3: Evaluation of Distribution Efficiency

Determine Distribution Efficiency by evaluating duct system before and after duct sealing or duct insulating using Building Performance Institute "Distribution Efficiency Look-Up Table".

$\Delta kWh = ((((DE_{after} - DE_{before}) / DE_{after}) * FLHcool * CapacityCool * TRFcool * \%Cool)/1,000 / \eta Cool) + (\Delta Therms * F_e * 29.3)$

Where:

DE_{after} = Distribution Efficiency after duct sealing, see table below[478]

DE_{before} = Distribution Efficiency before duct sealing, see table below[479]

Insulation	Sealing	Heating			Cooling		
		Attic	Basement	Vented Crawl	Attic	Basement	Vented Crawl
R-0	Leaky	69%	93%	74%	61%	81%	76%
	Average	73%	94%	78%	64%	87%	83%
	Tight	77%	95%	82%	73%	94%	91%
R-2	Leaky	76%	94%	80%	65%	83%	78%
	Average	82%	96%	85%	74%	88%	85%

[476] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

[477] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is assumed consistent with the baseline for 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[478] Building Performance Institute, Distribution Efficiency Look-up Tables, Climate Zones 4-5. https://www.bpi.org/sites/default/files/Guidance%20on%20Estimating%20Distribution%20Efficiency.pdf

Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown (for use in program evaluation only)[495]	N/A	N/A	1.32

[491] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[492] Note that the HSPF2 of a heat pump is equal to the COP * 3.412.

[493] Based on Building Performance Institute Inc., "Duct Efficiency Tables".

[494] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

[495] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is assumed consistent with the baseline for 2006-2014. Program or evaluation data should be used to improve this assumption if available.

For example, duct sealing in unconditioned space in a 36,000 Btu/H, 2.5 COP heat pump heated with estimated 85% distribution efficiency single family house in Springfield with the following duct evaluation results:

DE_{after} = 0.92

DE_{before} = 0.85

Energy Savings:

$\Delta kWh_{heating}$ = ((0.92 – 0.85)/0.92) * 1,708 * 36,000 * 1 * 1) / (2.5 * 0.85)) / 3,412

= 645 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$\Delta kW = \Delta kWh_{cooling}$/ FLHcool * CF

Where:

FLHcool = Full load cooling hours:

= Dependent on location as below:[496]

Climate Zone (City based upon)	FLHcool Single Family	FLHcool Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1,082	982
5 (Marion)	956	868
Weighted Average[497]		
ComEd	676	603
Ameren	875	791
Statewide	731	655

Use Multifamily if: Building meets utility's definition for multifamily and system serves single unit. For residential sized systems serving 2 or more units, assume single family hours. For central systems use Volume 2 Commercial and Industrial Measures.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)

= 68%[498]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during peak period)

= 46.6%[499]

FOSSIL FUEL SAVINGS

For homes with Fossil Fuel Heating:

[496] Based on Full Load Hours from ENERGY Star with adjustments made in a Navigant Evaluation, other cities were scaled using those results and CDD. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[497] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[498] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[499] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Methodology 1: Modified Blower Door Subtraction

Methodology 2: Pressurized Duct Test

ΔTherm = (((ΔCFM25$_{DL}$ / (InputCapacityHeat * 0.0123)) * FLHheat * InputCapacityHeat * TRFheat * %FossilHeat * (ηEquipment / ηSystem)) / 100,000

Where:

ΔCFM25$_{DL}$ = Duct leakage reduction in CFM25

InputCapacityHeat = Heating input capacity (Btu/hr)

=Actual

0.0123 = Conversion of Capacity to CFM (0.0123CFM / Btu/hr)[500]

FLHheat = Full load heating hours

=Dependent on location as below:[501]

Climate Zone (City based upon)	FLH_heat
1 (Rockford)	1924
2 (Chicago)	1726
3 (Springfield)	1708
4 (Belleville)	1195
5 (Marion)	1270
Weighted Average[502]	
ComEd	1766
Ameren	1543
Statewide	1700

TRFheat = Thermal Regain Factor for heating by space type

= 0.40 for Semi-Conditioned Spaces

= 1.0 for Unconditioned Spaces[503]

%FossilHeat = Percent of homes that have gas space heating

= 100 % for Natural Gas

= 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

[500] Based on Natural Draft Furnaces requiring 100 CFM per 10,000 Btu, Induced Draft Furnaces requiring 130CFM per 10,000Btu and Condensing Furnaces requiring 150 CFM per 10,000 Btu (rule of thumb from 'Practical Standards to Measure HVAC System Performance'). Data provided by GAMA during the federal rule-making process for furnace efficiency standards, suggested that in 2000, 24% of furnaces purchased in Illinois were condensing units. Therefore, a weighted average required airflow rate is calculated assuming a 50:50 split of natural v induced draft non-condensing furnaces, as 123 per 10,000Btu or 0.0123/Btu.

[501] Heating EFLH based on ENERGY Star EFLH for Rockford, Chicago, and Springfield and on NCDC/NOAA HDD for the other two cities. In all cases, the hours were adjusted based on average natural gas heating consumption in IL. During update cycle for version v.12, applied percent change of HDD60, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHheat values.

[502] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[503] Thermal regain for residential pipe insulation measures is discussed in Home Energy Services Impact Evaluation, prepared for the Massachusetts Residential Retrofit and Low Income Program Area Evaluation, Cadmus Group, Inc., August 2012.

= If unknown[504], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[505]					75.4%

Note: If a measure is supported by a gas and electric utility, utilize the assumptions above for the gas utility

100,000 = Converts Btu to therms

ηEquipment = Heating Equipment Efficiency

= Actual.[506] If not available, use 83%.[507]

ηSystem = Pre duct sealing Heating System Efficiency (Equipment Efficiency * Pre Distribution Efficiency)[508]

= Actual. If not available, use 70%[509]

[504] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[505] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

[506] The Equipment Efficiency can be obtained either by recording the AFUE of the unit, or performing a steady state efficiency test.
If there are more than one heating systems, the weighted (by consumption) average efficiency should be used.
If the heating system or distribution is being upgraded within a package of measures together with the insulation upgrade, the new average heating system efficiency should be used.

[507] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey). In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) = 0.829

[508] The Distribution Efficiency can be estimated via a visual inspection and by referring to a look up table such as that provided by the Building Performance Institute: (see 'DistributionEfficiencyTable-Blue Sheet') or by performing duct blaster testing.

[509] Estimated as follows: 0.829 * (1-0.15) = 0.70

For example, duct sealing in unconditioned space in a house in Springfield with an 80% AFUE, 105,000 Btu/H (input capacity) natural gas furnace and the following blower door test results:

Before: $CFM50_{Whole\ House}$ = 4800 CFM50

$CFM50_{Envelope\ Only}$ = 4500CFM50

House to duct pressure of 45 Pascals = 1.29 SCF (Energy Conservatory look up table)

After: $CFM50_{Whole\ House}$ = 4600 CFM50

$CFM50_{Envelope\ Only}$ = 4500CFM50

House to duct pressure of 43 Pascals = 1.39 SCF (Energy Conservatory look up table)

Duct Leakage:

$CFM50_{DL\ before}$ = (4800 – 4500) * 1.29

= 387 CFM

$CFM50_{DL\ after}$ = (4600 – 4500) * 1.39

= 119 CFM

Duct Leakage reduction at CFM25:

$\Delta CFM25_{DL}$ = (387 – 139) * 0.64 * (0.5 + 0.25)

= 119 CFM25

Energy Savings:

Pre Distribution Efficiency = 1 – (387/4800) = 92%

ηSystem = 80% * 92% = 74%

ΔTherm = ((119/ (105,000 * 0.0123)) * 1,708 * 105,000 * 1 *(0.8/0.74)) / 100,000

= 179 therms

Methodology 3: Evaluation of Distribution Efficiency

$$\Delta Therm = ((DE_{after} - DE_{before})/ DE_{after})) * FLHheat * InputCapacityHeat * TRFheat * \%FossilHeat * (\eta Equipment / \eta System)) / 100{,}000$$

Where:

DE_{after} = Distribution Efficiency after duct sealing, refer to table in electric savings section

DE_{before} = Distribution Efficiency before duct sealing, refer to table in electric savings section

Other factors as defined above.

For example, duct sealing in unconditioned space in a house in Springfield an 80% AFUE, 105,000 Btu/H (input capacity) natural gas furnace and the following duct evaluation results:

DE_{after} = 0.92

DE_{before} = 0.85

Energy Savings:

ηSystem = 80% * 85% = 68%

ΔTherm = (((0.92 – 0.85)/0.92) * 1,708 * 105,000 * 1 * 1 * (0.8/0.68)) / 100,067

= 160 therm

Mid-Life Adjustment

In order to account for the likely replacement of existing heating and cooling equipment during the lifetime of this

measure, a mid-life adjustment should be applied.

For electric HVAC, to calculate the adjustment, re-calculate the savings using the algorithms in the 'Electric Energy Savings' section using the following new baseline system efficiency assumptions:

Efficiency Assumption	System Type	New Baseline Efficiency
ηCool	Central AC	13.4 SEER2
	Heat Pump	14.3 SEER2
ηHeat	Heat Pump (7.5/3.412)	2.20 COP

For gas fueled systems, because the algorithm uses input capacity (which already accounts for the equipment efficiency), the *change* in equipment efficiency needs to be accounted for. Therefore, re-calculate the savings using the following algorithm:

Methodology 1: Modified Blower Door Subtraction

Methodology 2: Pressurized Duct Test

$$\Delta Therms = ((\Delta CFM25_{DL} / (InputCapacityHeat * 0.0123)) * FLHheat * InputCapacityHeat * TRFheat * \%FossilHeat * (\eta Equipment / (\eta Equipment_{New} * DE_{after})) / 100{,}000$$

Where:

$\eta Equipment_{New}$ = 80% AFUE

DE_{after} = Distribution efficiency after duct sealing

$= 1 – (CFM50_{DL\ After} / CFM50_{Whole\ House\ After})$

Methodology 3: Evaluation of Distribution Efficiency

$$\Delta Therms = ((DE_{after} – DE_{before})/ DE_{after})) * FLHheat * InputCapacityHeat * TRFheat * \%FossilHeat * (\eta Equipment / (\eta Equipment_{New} * DE_{after})) / 100{,}000$$

Where:

$\eta Equipment_{New}$ = 80% AFUE

DE_{after} = Distribution efficiency after duct sealing

= As evaluated using the Building Performance Institutes 'Distribution Efficiency Look-Up Table'

The re-calculated reduced annual savings should be applied following the assumed remaining useful life of the existing equipment, estimated to be 10 years.[510] Note: if the existing equipment efficiency is greater than the new baseline efficiency listed above, do not apply a mid-life adjustment.

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

[510] This is intentionally longer than the assumption found in the early replacement measures as the application of this measure will occur in a variety of homes and will not be targeting those homes appropriate for early replacement HVAC systems.

5.3.5 Furnace Blower Motor

DESCRIPTION

This measure describes savings from a brushless permanent magnet (BPM) motor (known and referred in this measure as an electronically commutated motor (ECM)) compared to a lower efficiency motor. Time of Sale and New Construction replacement scenarios no longer apply to this measure, as federal standards make ECM blower fan motors a requirement for residential furnaces.[511] Savings however are available from retrofitting an ECM motor into an existing furnace, or replacing an operational inefficient furnace with a new furnace with an ECM prior to the end of its life.

This measure characterizes the electric savings associated with the fan and the interactive negative therm savings due to a reduction in waste heat of the fan when operating in heating mode.

Savings decrease sharply with static pressure so duct improvements, and clean, low pressure drop filters can maximize savings. Savings occur when the blower is used for heating, cooling as well as when it is used for continuous ventilation, but only if the non-ECM motor would have been used for continuous ventilation too. If the resident runs the ECM blower continuously because it is a more efficient motor and would not run a non-ECM motor that way, savings are near zero and possibly negative. This characterization uses a 2016 Ameren Illinois study of ECM blower motors in Illinois, which accounted for the effects of this behavioral impact through surveyed results of impacted homeowners.

Retrofitting an existing blower motor with a new ECM reduces the potential impact of the high efficiency motor over a new system designed for an ECM blower motor because existing systems were not designed to capitalize and take advantage of the ECM's multi-staging features. Energy and demand savings are limited to the efficiency gains from the motor itself.

Note: as part of a Time of Sale measure, it is not appropriate to claim additional ECM fan savings due to installing a new furnace or CAC unit as ECM motors are now baseline for new furnaces and the SEER2/EER2 ratings of a CAC unit already account for this electrical load.

In an early replacement furnace situation, ECM fan heating savings can be claimed for the RUL of the existing furnace, and cooling savings can be claimed for the RUL of the CAC if an existing cooling unit is not replaced.

If a new CAC unit is installed in a home where the existing furnace is not replaced, heating ECM savings should only be claimed if it can be demonstrated that the new CAC motor will be used for the heating load.

This measure was developed to be applicable to the following program types: RF, EREP

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

A brushless permanent magnet (ECM) blower motor, also known by the trademark ECM, BLDC, and other names.

DEFINITION OF BASELINE EQUIPMENT

A non-ECM blower motor.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 6 years, which is the remaining life of existing furnaces.[512]

[511] As part of the code of federal regulations, energy conservation standards for covered residential furnace fans become effective on July 3, 2019 (10 CFR 430.32(y)). The expectation is the baseline will essentially become an ECM motor.

[512] While ECM blower motors have an effective useful life of 15 year (consistent with assumed life of a BPM/ECM motor, Appendix 8-E of the DOE Technical support documents for federal residential appliance standards) as this is a retrofit measure on an existing furnace blower motor, the remaining useful life of that equipment is used. For more detail, please see 5.3.7 Gas High Efficiency Furnace

DEEMED MEASURE COST

The capital cost for this measure as a retrofit should be actual if known; if unknown, assume $350.[513] In cases of furnace early replacements, it is assumed the incremental cost of the ECM is $0.

LOADSHAPE

Loadshape R08 - Residential Cooling

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

ECMs installed in high efficiency CACs and ASHPs do not generate peak demand cooling savings if demand savings are claimed for these systems. However, some savings are realized for fans operating in circulation mode, even during peak demand cooling periods. Circulation mode operation during peak cooling periods would only occur when a system is not operating in cooling mode, with the percent time in circulation mode calculated using the summer system peak and PJM peak coincidence factors. A metering study found 23% of fans operated continuously during the summer peak periods;[514] therefore, ECMs do generate some demand savings during peak periods (when the system is not cooling). ECMs installed with CACs or ASHPs not receiving a rebate improve the cooling efficiency and therefore generate additional peak demand savings (when the system is cooling). Demand savings vary with system size and can be calculated using factors listed in the demand savings calculation table in the next section which incorporate coincidence with peak in their calculation.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = Capacity_cooling * kWhSavingsPerTon$$

Where:

Capacity_cooling	= Capacity of cooling system in tons
	= Actual (1 ton = 12,000Btu/hr)
kWhSavingsPerTon	= Blower fan kWh savings per ton of cooling[515]
	The per-ton energy savings values vary by system installation scenario and location as provided below. Assumptions are also provided for installation with no or unknown cooling system.

[513] The cost of a typical replacement motor is estimated at $180 based on quotes from online suppliers, plus $17 for the bracket. Typical labor costs are estimated at between $140 and $190 based on program experience provided by Staples in April 2022. A total retrofit measure cost is therefore estimated at $350.

[514] See Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018'.

[515] Tons of cooling was determined to be the most straightforward multiplier to apply to systems in which the BPM is installed. The basis of the values and for more information see Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018'.

Region	Existing ASHP	Existing CAC	Furnace, No Cooling System*	Furnace, Cooling System unknown* [516]
Rockford	247	229	210	223
Chicago	245	230	208	222
Springfield	249	231	203	221
Belleville	247	235	196	222
Marion	242	231	196	219
Average	247	230	206	222
*Multiply kWh saved value by 2 tons for furnaces <70 kBTU, by 3 tons for furnaces 70 kBTU – 90 kBTU and by 4 tons for furnaces 90+ kBTU.				

For example, an BPM installed in an existing 3-ton, 16 SEER CAC in a home in Marion:

ΔkWh = 3 * 231

= 693 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = Capacity_cooling * kWSavingsPerTon

Where:

kWSavingsPerTon = Blower fan kW savings per ton of cooling[517]

The per-ton energy savings values vary by system installation scenario and location as provided below. Assumptions are also provided for installation with no or unknown cooling system.

Demand Savings Type	Existing ASHP	Existing CAC	Furnace, No Cooling System*	Furnace, Cooling System unknown* [518]
SSP	0.085	0.085	0.013	0.065
PJM	0.064	0.064	0.009	0.048
*Multiply kWh saved value by 2 tons for furnaces <70 kBTU, by 3 tons for furnaces 70 kBTU – 90 kBTU and by 4 tons for furnaces 90+ kBTU.				

[516] Unknown cooling system values are based on a weight of 66% existing CAC and 34% no cooling factors. Based on 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey)

[517] Tons of cooling was determined to be the most straightforward multiplier to apply to systems in which the BPM is installed. The basis of the values and for more information see Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018'.

[518] Unknown cooling system values are based on a weight of 66% existing CAC and 34% no cooling factors. Based on 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey)

For example, a BPM installed in an existing 3-ton, 16 SEER CAC receiving a rebate in a home in Marion:

ΔkW_{ssp} = 3 * 0.0085

= 0.0255 kW

ΔkW_{pjm} = 3 * 0.064

= 0.192 kW

FOSSIL FUEL SAVINGS

$$\Delta therms^{519} = - HeatingkWhSavings * 0.03412 / AFUE$$

Where:

HeatingkWhSavings = Heating kWh savings per ton of cooling[520]

Use the location-specific values in the following table to determine heating savings based on the size of the cooling system. If cooling size is unknown, assume 2 tons for furnaces <70 kBTU, 3 tons for furnaces 70 kBTU – 90 kBTU, and 4 tons for furnaces 90+ kBTU. If heating size is unknown or if the system does not include cooling, assume a 3-ton system.

Region	Heating Savings (kWh per ton of cooling)
Rockford	61
Chicago	59
Springfield	50
Belleville	39
Marion	39
Average	56

0.03412 = Converts kWh to therms

AFUE = Efficiency of the Furnace

= Actual. If unknown, assume 64.4 AFUE% for the existing furnace.[521]

For example, an ECM installed in an existing 3-ton CAC and 95% AFUE furnace in a home in Marion:

Δtherms = (-39 kWh * 3 tons * 0.03412) / 0.95

Δtherms = - 4.2 therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

[519] The blower fan is in the heating duct so all, or very nearly all, of its waste heat is delivered to the conditioned space. Negative value since this measure will increase the heating load due to reduced waste heat.

[520] Tons of cooling was determined to be the most straightforward multiplier to apply to systems in which the BPM is installed. The basis of the values and for more information see Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018'.

REVIEW DEADLINE: 1/1/2028

5.3.6 Gas High Efficiency Boiler

DESCRIPTION

High efficiency boilers achieve most gas savings through the utilization of a sealed combustion chamber and multiple heat exchangers that remove a significant portion of the waste heat from flue gasses. Because multiple heat exchangers are used to remove waste heat from the escaping flue gasses, some of the flue gasses condense and must be drained.

This measure characterizes:

a) Time of Sale:

   a. The installation of a new high efficiency, gas-fired hot water boiler in a residential location meeting efficiency specifications determined by the program. This could relate to the replacement of an existing unit at the end of its useful life, or the installation of a new system in a new home.

b) Early Replacement:

   Early Replacement determination will be based on meeting the following conditions:

   - The existing unit is operational when replaced, or
   - The existing unit requires minor repairs (<$709).[522]
   - All other conditions will be considered Time of Sale.

   The Baseline AFUE of the existing unit replaced:

   - If the AFUE of the existing unit is known the Baseline AFUE is the actual AFUE value of the unit replaced.
   - If the AFUE of the existing unit is unknown, use assumptions in variable list below ($AFUE_{Exist}$).
   - If the operational status or repair cost of the existing unit is unknown, use time of sale assumptions.

   A weighted average early replacement rate is provided for use in programs when the actual baseline early replacement rates are unknown.[523]

Deemed Early Replacement Rates for Boilers

	Deemed Early Replacement Rate
Early Replacement Rate for Boiler participants	7%

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed Boiler must meet the requirements determined by the program. For reference the ENERGY STAR[524] specification is an AFUE rated at or greater than 90% and input capacity less than

[522] The Technical Advisory Committee agreed that if the cost of repair is less than 20% of the new baseline replacement cost it can be considered early replacement. Note the non-inflated cost is used as this would be a cost consideration in the program year.

[523] Based upon research from "Home Energy Efficiency Rebate Program GPY2 Evaluation Report" which outlines early replacement rates for both primary and secondary central air cooling (CAC) and residential furnaces. This is used as a reasonable proxy for boiler installations since boiler specific data is not available. Report presented to Nicor Gas Company February 27, 2014.

[524] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

300,000 Btu/hr.[525]

DEFINITION OF BASELINE EQUIPMENT

Time of sale: The baseline equipment for this measure is a new, gas-fired, standard-efficiency water boiler. The baseline AFUE is assumed to be 84% and is based on minimum federal appliance standards for boilers manufactured on or after January 15, 2021.[526]

Early replacement: The baseline for this measure is the efficiency of the existing equipment for the assumed remaining useful life of the unit and the new baseline as defined above for the remainder of the measure life. Consistent with TRM Volume 1 Section 2.3.1 for midstream programs or other cases where the existing condition is unknown, it may be appropriate to apply a deemed percent split of Time of Sale and Early Replacement assumptions based on evaluation results

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 25 years.[527]

Early replacement: Remaining life of existing equipment is assumed to be 8 years.[528]

DEEMED MEASURE COST

Time of sale: The incremental install cost for this measure is dependent on efficiency:[529]

Efficiency Level	Installation Cost	Incremental Install Cost
Baseline	$8,820	n/a
AFUE < 95%	$10,141	$1,321
AFUE ≥ 95%	$10,710	$1,891

Early Replacement: The full installation cost is provided in the table above. The assumed deferred cost (after 8 years) of replacing existing equipment with a new baseline unit is assumed to be $10,563.[530] This cost should be discounted to present value using the nominal discount rate.

LOADSHAPE

2 (Chicago)	976
3 (Springfield)	836
4 (Belleville)	645
5 (Marion)	656
Weighted Average[533]	
ComEd	978
Ameren	800

[531] The two equations are provided to show how savings are determined during the initial phase of the measure (existing to efficient) and the remaining phase (new baseline to efficient). In practice, the screening tools used may either require a First Year savings (using the first equation) and then a "number of years to adjustment" and "savings adjustment" input which would be the (new base to efficient savings)/(existing to efficient savings).

[532] Full load hours for Chicago, are based on findings in 'Energy Efficiency / Demand Response Nicor Gas Plan Year 1 (6/1/2011-5/31/2012) Research Report: Furnace Metering Study (August 1, 2013), prepared by Navigant Consulting, Inc. Values for other cities are then calculated by comparing relative HDD at base 60F.

[533] Weighting for Ameren is based on gas accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

Climate Zone (City based upon)	EFLH[532]
Statewide	928

$AFUE_{Exist}$ = Existing Boiler Annual Fuel Utilization Efficiency Rating

= Use actual AFUE rating where it is possible to measure or reasonably estimate. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[534] or if unknown, assume 61.6 AFUE%.[535] If unknown value is used, it should not be derated by age.

$AFUE_{Base}$ = Baseline Boiler Annual Fuel Utilization Efficiency Rating

= 84% if implemented in 2022 and beyond

$AFUE_{Eff}$ = Efficent Boiler Annual Fuel Utilization Efficiency Rating

= Actual. If unknown, use defaults dependent on tier as listed below:[536]

Measure Type	AFUE(eff)
ENERGY STAR®	90%
AFUE 90%	92.5%
AFUE 95%	95%

Time of Sale:

For example, a 100,000 Btu/h, 90% AFUE ENERGY STAR boiler purchased and installed near Springfield in 2022:

ΔTherms = (836 * 100,000 * (0.90/0.84 – 1)) / 100,000

= 59.7 Therms

Early Replacement:

For example, an existing function boiler with unknown efficiency is replaced with a 100,000 Btu/h, 90% AFUE ENERGY STAR boiler purchased and installed in Springfield in 2022:

ΔTherms for remaining life of existing unit (1st 8 years):

= (836 * 100,000 * (0.90/0.616 – 1)) / 100,000

= 385.4 Therms

ΔTherms for remaining measure life (next 17 years):

= (836 * 100,000 * (0.90/0.84 – 1)) / 100,000

= 59.7 Therms

REVIEW DEADLINE: 1/1/2029

5.3.7 Gas High Efficiency Furnace

DESCRIPTION

High efficiency furnace features may include improved heat exchangers and modulating multi-stage burners.

This measure characterizes:

a) Time of sale:
   a. The installation of a new high efficiency, gas-fired condensing furnace in a residential location meeting efficiency specifications determined by the program. This could relate to the replacement of an existing unit at the end of its useful life, or the installation of a new system in a new home.

b) Early Replacement:

   Early Replacement determination will be based on meeting the following conditions:
   - The existing unit is operational when replaced, or
   - The existing unit requires minor repairs (<$528).[537]
   - All other conditions will be considered Time of Sale.

   The Baseline AFUE of the existing unit replaced:
   - If the AFUE of the existing unit is known, the Baseline AFUE is the actual AFUE value of the unit replaced.
   - If the AFUE of the existing unit is unknown, use assumptions in variable list below (AFUE(exist)).
   - If the operational status or repair cost of the existing unit is unknown, use time of sale assumptions.

   A weighted average early replacement rate is provided for use in programs when the actual baseline early replacement rate is unknown.[538]

Deemed Early Replacement Rates For Furnaces

Replacement Scenario for the Furnace	Deemed Early Replacement Rate
Early Replacement Rate for Furnace-only participants	7%
Early Replacement Rate for a furnace participant when the furnace is the Primary unit in a Combined System Replacement (CSR) project	14%
Early Replacement Rate for a furnace participant when the furnace is the Secondary unit in a CSR project	46%

Verified Quality Installation

This approach uses in-field measurement and interpretation of static pressures, identification and plotting of airflow, airflow measurement, temperature measurement and diagnostics, pressure measurements and duct design, and BTU measurement to ensure that newly installed equipment is operating according to manufacturers' published potential performance. Installed equipment operating efficiency is largely dependent on the efficiency rating of the

[537] The Technical Advisory Committee agreed that if the cost of repair is less than 20% of the new baseline replacement cost it can be considered early replacement. Note the non-inflated cost is used as this would be a cost consideration in the program year.

[538] Based upon research from "Home Energy Efficiency Rebate Program GPY2 Evaluation Report" which outlines early replacement rates for both primary and secondary central air cooling (CAC) and residential furnaces. The unit (furnace or CAC unit) that initially caused the customer to contact a trade ally is defined as the "primary unit". The furnace or CAC unit that was also replaced but did not initially prompt the customer to contact a trade ally is defined as the "secondary unit". This evaluation used different criteria for early replacement due to the availability of data after the fact; cost of any repairs < $550 and age of unit < 20 years. Report presented to Nicor Gas Company February 27, 2014.

equipment, the skill of the installation contractor, the degree to which the equipment has aged or drifted from initial settings, and the system level constraints. When one or more of these key dependencies are operating sub-optimally, the overall efficiency of the equipment is degraded. A Verified Quality Install identifies sub-optimal performance and prescribes a solution during furnace installation.

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a residential sized (input energy less than 225,000 Btu/hr) natural gas fired furnace with an Annual Fuel Utilization Efficiency (AFUE) rating exceeding the program requirements. For reference the ENERGY STAR[539] specification is an AFUE rated at or greater than 95% with an ECM motor and input capacity less than 225,000 Btu/hr.[540]

DEFINITION OF BASELINE EQUIPMENT

Time of Sale: The current Federal Standard for gas furnaces is an AFUE rating of 80%. The baseline will be adjusted when the Federal Standard is updated.

Early replacement: The baseline for this measure is the efficiency of the existing equipment for the assumed remaining useful life of the unit and a new baseline 80% AFUE unit for the remainder of the measure life. Consistent with TRM Volume 1 Section 2.3.1 for midstream programs or other cases where the existing condition is unknown, it may be appropriate to apply a deemed percent split of Time of Sale and Early Replacement assumptions based on evaluation results.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years.[541]

For early replacement: Remaining life of existing equipment is assumed to be 6 years.[542]

DEEMED MEASURE COST

Time of sale: The incremental installed cost (retail equipment cost plus installation cost) for this measure depends on efficiency as listed below:[543]

AFUE	Installed Cost	Incremental Installed Cost
Baseline	$4,019	n/a
≤ 95%	$4,327	$307
> 95% - < 97%	$4,524	$505
≥ 97%	$4,699	$679

Early Replacement: Actual install costs should be used if available. The deemed full installed cost is provided in the table above. The assumed deferred cost (after 6 years) of replacing existing equipment with a new 80% baseline unit is assumed to be $4,601.[544] This cost should be discounted to present value using the nominal discount rate. For

[539] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[540] ENERGY STAR Program Requirements, Product Specifications for Furnaces, version 4.1, effective February 1, 2013.
[541] Table 8.3.3 The Technical support documents for federal residential appliance standards.
[542] Assumed to be one third of effective useful life
[543] In 2025, a working group was created to update costs for residential HVAC equipment. Heat Pump and Central Air Conditioning costs are based upon Ameren program data. Furnace and Boiler costs are based on Ameren, Nicor, People's Gas, and North Shore Gas program data. Baseline costs have been determined using ratios from Updated Buildings Sector Appliance and Equipment Costs and Efficiencies by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration, March 2023. See file "HVAC Costs – 071825_VEIC.xlsx" for more details.
[544] $4019 inflated for 6 years using assumed inflation rate of 2.28%.

furnaces installed in mobile homes, add an extra $750 to both the full install cost and the deferred baseline cost to account for increased equipment and labor costs associated with this install.[545]

Verified Quality Installation: The additional design and installation work associated with verified quality installation has been estimated to take 1-2 hours (Tim Hanes, ESI). At $40/hr, VQI adds $60 to the installed cost.

[552] Code of Federal Regulations, effective November, 2015 (10 CFR 432(e)).
[553] Average AFUE based on analysis of Nicor Gas 2019 Home Energy Efficiency Rebate Program participant tracking data, prepared by Guidehouse, Inc., based on 12,549 furnaces rebated at the 95 AFUE Tier, and 1,103 furnaces rebated at the 97 AFUE Tier.

Derating(base) =Baseline furnace AFUE derating

= 6.4%[554]

Derating(eff) =Efficent furnace AFUE derating

=0% if verified quality installation is performed

=6.4% if verified quality installation is not performed or unknown[555]

Time of Sale:

For example, a 95% AFUE, 80,000Btuh furnace purchased and installed with verified quality installation for an existing home near Rockford:

ΔTherms = ((1022 * 80,000)/(1-0) * (((0.95 * (1-0)) / (0.8 * (1-0.064))) – 1)) / 100000

= 220 therms

For example, a 95% AFUE, 80,000 Btuh furnace purchased and installed without verified quality installation for an existing home near Rockford:

ΔTherms = ((1022 * 80,000)/(1-0.064) * (((0.95 * (1-0.064)) / (0.8 * (1-0.064))) – 1)) / 100000

=164 therms

Early Replacement:

For example, an existing functioning furnace with unknown efficiency is replaced with an 95% AFUE, 80,000 Btuh furnace using quality installation in Rockford:

ΔTherms for remaining life of existing unit (1st 6 years):

= ((1022 * 80,000)/(1-0) * (((0.95 * (1-0)) / (0.644 * (1-0.064))) – 1)) / 100000

= 471 therms

ΔTherms for remaining measure life (next 14 years):

= ((1022 * 80,000)/(1-0) * (((0.95 * (1-0)) / (0.8 * (1-0.064))) – 1)) / 100000

= 220 therms

5.3.8 Ground Source Heat Pump

DESCRIPTION

This measure characterizes the installation of a Ground Source Heat Pump under the following scenarios:

a) New Construction:
   i. The installation of a new residential sized Ground Source Heat Pump system meeting minimum efficiency standards determined by the program in a new home.
   ii. Note the baseline in this case should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition.

b) Time of Sale:
   i. The planned installation of a new residential sized Ground Source Heat Pump system meeting minimum efficiency standards determined by the program to replace an existing system(s) that does not meet the criteria for early replacement described in section c below.
   ii. Note the baseline in this case is an equivalent replacement system to that which exists currently in the home. Where unknown, the baseline should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition. The calculation of savings is dependent on whether an incentive for the installation has been provided by both a gas and electric utility, just an electric utility or just a gas utility.
   iii. Additional DHW savings are calculated based upon the fuel and efficiency of the existing unit.

c) Early Replacement/Retrofit:
   i. The early removal of functioning components of the electric or gas space heating and/or cooling systems from service, prior to the natural end of life, and replacement with a new high efficiency Ground Source Heat Pump system.
   ii. Note the baseline in this case is the existing equipment being replaced. The calculation of savings is dependent on whether an incentive for the installation has been provided by both a gas and electric utility, just an electric utility or just a gas utility.
   iii. Additional DHW savings are calculated based upon the fuel and efficiency of the existing unit.
   iv. Early Replacement determination will be based on meeting the following conditions:
      - The existing unit is operational when replaced, or
      - The existing unit requires minor repairs, defined as costing less than:[556]

Existing System	Maximum repair cost
Air Source Heat Pump	$276 per ton
Central Air Conditioner	$190 per ton
Boiler	$709
Furnace	$528
Ground Source Heat Pump	<$249 per ton

      - All other conditions will be considered Time of Sale.
   v. The Baseline efficiency of the existing unit replaced:
      - Is the actual efficiency value of the unit replaced if known.
      - If the efficiency of the existing unit is unknown, use assumptions in variable list below (SEER2, HSPF2 or AFUE exist).
      - If the operational status or repair cost of the existing unit is unknown use time of sale

[556] The Technical Advisory Committee agreed that if the cost of repair is less than 20% of the new baseline replacement cost it can be considered early replacement.

assumptions.

This measure was developed to be applicable to the following program types: TOS, NC, EREP. If applied to other program types, the measure savings should be verified.

For ground source heat pump central systems in multifamily buildings, use Volume 2 Commercial and Industrial Measures.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, the efficient equipment must be a Ground Source Heat Pump unit meeting the minimum efficiency level standards determined by the program effective at the time of installation. For reference, the current ENERGY STAR[557] specifications are detailed below:

ENERGY STAR Requirements (Effective January 1, 2012)

Product Type	Cooling EER	Heating COP
Water-to-air		
Closed Loop	17.1	3.6
Open Loop	21.1	4.1
Water-to-Water		
Closed Loop	16.1	3.1
Open Loop	20.1	3.5
DGX		
DGX-to-Air	16	3.6
DGX-to-Water	15	3.1

The following conversion factors are recommended for use if the efficient equipment is not rated under the new testing procedure:[558]

SEER2 = SEER * X

EER2 = EER2 * X

HSPF2 = HSPF2 * X

Where:

X	SEER	EER	HSPF
Ducted	0.95	0.95	0.85

DEFINITION OF BASELINE EQUIPMENT

For these products, baseline equipment includes Air Conditioning, Space Heating and Water Heating.

New Construction:

To calculate savings with an electric baseline, the baseline equipment is assumed to be an Air Source Heat Pump meeting the Federal Standard efficiency level and a Federal Standard electric hot water heater. The Federal Standard

[557] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[558] Consortium for Energy Efficiency (CEE), Testing, Testing, M1, 2, 3, Transitioning to New Federal Minimum Standards, CEE Summer Program Meeting, June 10, 2022.

efficiency levels for an Air Source Heat Pump are as follows[559]:

- Split system heat pump – 14.3 SEER2, 9.4 EER2 and 7.5 HSPF2
- Single-package heat pump – 13.4 SEER2, 8.5 EER2 and 6.7 HSPF2

To calculate savings with a furnace/central AC baseline, the baseline equipment is assumed to be an 80% AFUE Furnace and central AC meeting the Federal Standard efficiency level; 13.4 SEER2, 10.6 EER2[560]. If a gas water heater, the Federal Standard baseline is calculated as follows; 0.6483 – (0.0017 * storage capacity in gallons) for tanks<=55 gallons and 0.7897 − (0.0004 × storage capacity in gallons) for greater than 55 gallon storage water heaters.[561] For a 40-gallon storage water heater this would be 0.58 EF.

Time of Sale: The baseline for this measure is a new replacement unit of the same system type as the existing unit, meeting the baselines provided below.

Unit Type	Efficiency Standard
ASHP	14.3 SEER2 9.4 EER2, 7.5 HSPF2
Natural Gas or LP Furnace	80% AFUE
Natural Gas or LP Boiler	84% AFUE
Oil Furnace	83% AFUE
Oil Boiler	86% AFUE
Central AC	13.4 SEER2, 10.6 EER2

Early replacement / Retrofit: The baseline for this measure is the efficiency of the *existing* heating, cooling and hot water equipment for the assumed remaining useful life of the existing unit and a new baseline heating and cooling system for the remainder of the measure life (as provided in table above).

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 25 years.[562]

For early replacement, the remaining life of existing equipment is assumed to be 6 years for ASHP and Central AC, 6 years for furnace, 8 years for boilers and GSHP[563] and 25 years for electric resistance.[564]

DEEMED MEASURE COST

New Construction and Time of Sale: The actual installed cost of the Ground Source Heat Pump (including any necessary electrical or distribution upgrades required) should be used (default of $3957 per ton),[565] minus the

[559] The 2023 federal standards (10 CFR 430.32(c)(5)) are in terms of an updated metric, depicted as SEER2 and HSPF2 and manufacturers must certify their products meet the standard according to the new test procedure and new metrics. The updated test method as well as the updated energy conservation standards were negotiated under the appliance standards and rulemaking federal advisory committee (ASRAC) in accordance with the Federal Advisory Committee Act (FACA) and the negotiated rulemaking act. An equivalent stringency of these new standards for split system heat pumps are 15 SEER and 8.8 HSPF and for single-package heat pumps are 14 SEER and 8 HSPF, as detailed in: Federal Code of Regulations, Energy Conservation Program: Energy Conservations Standards for residential Central Air Conditioners and Heat Pumps; Confirmation of effective date and compliance date for direct final rule, May 26, 2017, Docket: EERE-2014-BT-STD-0048 (https://www.regulations.gov/document/EERE-2014-BT-STD-0048-0200)

[560] The Federal Standard does not include an EER requirement. The value provided is based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018'.

[561] Minimum Federal standard as of 4/16/2015.

[562] System life of indoor components as per DOE estimate (see 'Geothermal Heat Pumps Department of Energy'). The ground loop has a much longer life, but the compressor and other mechanical components are the same as an ASHP.

[563] Assumed to be one third of effective useful life of replaced equipment.

[564] Assume full measure life (16 years) for replacing electric resistance as we would not expect that resistance heat would fail during the lifetime of the efficient measure.

[565] Based on data provided in 'Results of HomE geothermal and air source heat pump rebate incentives documented by IL electric cooperatives'.

assumed installation cost of the baseline equipment from table below for electric equipment, or assume $4,019 for a new baseline 80% AFUE furnace or $8,820 for a new baseline 84% AFUE boiler.[566]

Baseline Equipment Type	Capacity Range	Baseline Cost per Ton[567]
Centrally Ducted Air Source Heat Pumps	< 2 tons	$4,602
	≥ 2 to < 3 tons	$3,691
	≥ 3 to < 4 tons	$3,093
	≥ 4 tons	$2,992
Ductless Minisplit Heat Pumps	< 1 ton	$8,156
	≥ 1 to < 2 tons	$5,356
	≥ 2 to < 3 tons	$3,704
	≥ 3 tons	$3,670
Central Air Conditioning	< 2 tons	$2,340
	≥ 2 to < 3 tons	$1,900
	≥ 3 tons	$1,500

Early Replacement: The actual full installation cost of the Ground Source Heat Pump should be used (including any necessary electrical or distribution upgrades required). If the install cost is unknown a default is provided above, however because these assumptions do not include any additional costs that may be required for fuel switch scenarios, these defaults should not be used and actual costs should always be used for fuel switch measures.

The assumed deferred cost (after the appropriate number of years described above in the 'Deemed Lifetime of Efficient Equipment' section) of replacing existing equipment with a new baseline unit is presented in the table below for electric equipment, or assume $4,601 for a new baseline 80% AFUE furnace or $10,563 for a new baseline 84% AFUE boiler.[568] This future cost should be discounted to present value using the nominal societal discount rate.

Equipment Type	Capacity Range	Deferred Baseline Cost per Ton
Centrally Ducted Air Source Heat Pumps	< 2 tons	$5,268
	≥ 2 to < 3 tons	$4,226
	≥ 3 to < 4 tons	$3,541
	≥ 4 tons	$3,425
Ductless Minisplit Heat Pumps	< 1 ton	$9,337
	≥ 1 to < 2 tons	$6,132
	≥ 2 to < 3 tons	$4,240
	≥ 3 tons	$4,202
Central Air Conditioning	< 2 tons	$2,679
	≥ 2 to < 3 tons	$2,175
	≥ 3 tons	$1,717

Fuel switch scenarios are likely to require additional installation work which may include adding new electrical circuits, capping existing gas lines and upgrading electrical panels. These costs are likely to range significantly and actual values should be used wherever possible. The total of any additional electrification costs should be divided across all applicable measures weighted by total MMBtu savings.

[566] In 2025, a working group was created to update costs for residential HVAC equipment. Heat Pump and Central Air Conditioning costs are based upon Ameren program data. Furnace and Boiler costs are based on Ameren, Nicor, People's Gas, and North Shore Gas program data. Baseline costs have been determined using ratios from Updated Buildings Sector Appliance and Equipment Costs and Efficiencies by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration, March 2023. See file "HVAC Costs – 071825_VEIC.xlsx" for more details.

[567] Ibid

[568] All baseline replacement costs are consistent with their respective measures and include inflation rate of 2.28%.

LOADSHAPE

Loadshape R10 - Residential Electric Heating and Cooling (if replacing gas heat and central AC)[569]

Loadshape R09 - Residential Electric Space Heat (if replacing electric heat with no cooling)

Loadshape R10 - Residential Electric Heating and Cooling (if replacing ASHP)

Note for purpose of cost effectiveness screening a fuel switch scenario, the heating kWh increase and cooling kWh decrease should be calculated separately such that the appropriate loadshape (i.e., Loadshape R09 - Residential Electric Space Heat and Loadshape R08 – Residential Cooling respectively) can be applied.

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Heat Pumps (during utility peak hour)

= 72%[570]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Heat Pumps (average during PJM peak period)

= 46.6%[571]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS AND FOSSIL FUEL SAVINGS

Non-fuel switch measures:

ΔkWh = GSHPSiteCoolingImpact + GSHPSiteHeatingImpact + ElectricFurnaceFanSavings + GSHPSiteDHWImpact

GSHPSiteCoolingImpact = $[FLHcool * Capacity_cooling * (1/SEER2_{base} – 1/EER2_{PL})/1000]$

GSHPSiteHeatingImpact = $[HeatLoad* (1/HSPF2_{base} – 1/(COP_{PL} * 3.412))/1000]$ +

ElectricFurnaceFanSavings[572] = FurnaceFlag * [Heating savings] * F_e

GSHPSiteDHWImpact = $[ElecDHW * \%DHWDisplaced * ((1/EF_{ELEC} * GPD * Household * 365.25 * \gamma Water * (T_{OUT} – T_{IN}) * 1.0) / 3412)]$

Fuel switch measures:

Fuel switch measures must produce positive total lifecycle energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows (note for early replacement measures the lifetime savings should be calculated by calculating savings for the remaining useful life of the existing equipment and for the remaining

[569] The baseline for calculating electric savings is an Air Source Heat Pump.
[570] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[571] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[572] If replacing an electric furnace only. The HSPF rating of a heat pump accounts for the fan consumption, however the HSPF rating of an electric furnace does not. Therefore, additional fan savings should be claimed.

measure life):

SiteEnergySavings (MMBTUs) = FuelSwitchSavings + NonFuelSwitchSavings

FuelSwitchSavings = GasHeatReplaced – GSHPSiteHeatConsumed

NonFuelSwitchSavings = GasFurnaceFanSavings + GSHPSiteCoolingImpact + GSHPSiteWaterImpact

GasHeatReplaced = [(HeatLoad * 1/$AFUE_{base}$) / 1,000,000]

GasFurnaceFanSavings = (FurnaceFlag * HeatLoad * 1/$AFUE_{base}$ * F_e) / 1,000,000

GSHPSiteHeatConsumed = [HeatLoad * (1/(COP_{PL} * 3.412))/1000] * 3412) / 1,000,000

GSHPSiteCoolingImpact = [FLHcool * Capacity_GSHPcool * (1/$SEER2_{base}$ – 1/$EER2_{PL}$)/1000] * 3412) / 1,000,000

$GSHPSiteWaterImpact_{Gas}$ = (%DHWDisplaced * (1/EF_{Gas} * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0)) / 1,000,000)

$GSHPSiteWaterImpact_{Electric}$ = (%DHWDisplaced * (1/EF_{Elec} * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0)) / 1,000,000

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Note for Early Replacement measures, the efficiency and Fe terms of the existing unit should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 6 years for furnace, 8 years for boilers or GSHP, 15 years for electric resistance), and the efficiency and Fe terms for a new baseline unit should be used for the remaining years of the measure. See assumptions below.

Where:

FLHcool = Full load cooling hours

Dependent on location as below:[573]

[573] Based on Full Load Hours from ENERGY STAR with adjustments made in a Navigant Evaluation, other cities were scaled using those results and CDD. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

Climate Zone (City based upon)	FLHcool Single Family	FLHcool Multifamily	FLH_cooling (weatherized multifamily) [574]
1 (Rockford)	547	499	320
2 (Chicago)	709	629	403
3 (Springfield)	779	707	453
4 (Belleville)	1082	982	630
5 (Marion)	956	868	557
Weighted Average[575]			
ComEd	676	603	386
Ameren	875	791	507
Statewide	731	655	420

Use Multifamily if: Building meets utility's definition for multifamily and system serves single unit. For residential sized systems serving 2 or more units, assume single family hours. For central systems use Volume 2 Commercial and Industrial Measures.

Capacity_GSHPcool = Cooling Output Capacity of Ground Source Heat Pump (Btu/hr)

= Actual (1 ton = 12,000Btu/hr)

SEER2base = SEER2 Efficiency of baseline unit. For early replacment measures, the actual SEER/SEER2 rating where it is possible to measure or reasonably estimate should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 8 years for GSHP). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[576] or if unknown assume default provided below. If unknown value is used, it should not be derated by age.

Baseline/Existing Cooling System	SEER2base		
	Early Replacement (Remaining useful life of existing equipment)	Early Replacement (Remaining measure life)	Time of Sale or New Construction
Air Source Heat Pump	9.2 SEER2[577]	14.3 SEER2[578]	
Ground Source Heat Pump	13.4 SEER2[579]	14.3 SEER2	
Central AC	9.2 SEER2[580]	13.4 SEER2[581]	
No central cooling	13.4 SEER2[582]	13.4 SEER2	

[574] *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015. The multifamily units within this study had undergone significant shell improvements (air sealing and insulation) and therefore this set of assumptions is only appropriate for units that have recently participated in a weatherization or other shell program. Note that the FLHcool where recalculated based on existing efficiencies consistent with the TRM rather than from the metering study.

[575] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[576] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[577] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018', converted to SEER2.

[578] Minimum Federal Standard as of 1/1/2023

[579] Estimate of existing GSHP efficiency is based converting 12 EER (estimate based upon Navigant, 2018 "EIA – Technology Forecast Updates – Residential and Commercial Building Technologies – Reference Case") to SEER. Converted to SEER2.

[580] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018' Converted to SEER2.

[581] Minimum Federal Standard; Federal Register, Vol. 66, No. 14, Monday, January 22, 2001/Rules and Regulations, p. 7170-7200.

[582] Assumes that the decision to replace existing systems includes desire to add cooling.

$EER2_{PL}$ = Part Load EER2 Efficiency of efficient GSHP unit[583]

= Actual installed

HeatLoad = Calculated heat load for the building

= FLH_GSHPheat * Capacity_GSHPheat

FLH_GSHPheat = Full load hours of heat pump heating

Dependent on location as below:[584]

Climate Zone (City based upon)	FLH_heat
1 (Rockford)	1924
2 (Chicago)	1726
3 (Springfield)	1708
4 (Belleville)	1195
5 (Marion)	1270
Weighted Average[585] ComEd Ameren Statewide	 1766 1547 1700

Capacity_GSHPheat = Heating Output Capacity of Ground Source Heat Pump (Btu/hr)

= Actual (1 ton = 12,000Btu/hr)

$HSPF2_{base}$ =Heating Seasonal Performance Factor of baseline heating system (kBtu/kWh), converted to HSPF2 if rating is in HSPF. For early replacement measures, use actual HSPF/HSPF2 rating where it is possible to measure or reasonably estimate for the remaining useful life of the existing equipment (6 years for ASHP, 8 years for GSHP or 15 years for electric resistance). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[586] or if unknown assume default. If unknown value is used, it should not be derated by age.

[583] As per conversations with David Buss territory manager for Connor Co, the SEER and COP ratings of an ASHP equate most appropriately with the part load EER and COP of a GSHP.

[584] Heating EFLH based on ENERGY STAR EFLH for Rockford, Chicago, and Springfield and on NCDC/NOAA HDD for the other two cities. In all cases, the hours were adjusted based on average natural gas heating consumption in IL. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of HDD60, NCDC/NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHheat values

[585] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[586] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

Baseline/ Existing Heating System	HSPF2_base		
	Early Replacement (Remaining useful life of existing equipment)	Early Replacement (Remaining measure life)	Time of Sale or New Construction
Air Source Heat Pump	4.91 HSPF2[587]	7.5 HSPF2[588]	
Ground Source Heat Pump	7.5 HSPF2[589]	7.5 HSPF2	
Electric Resistance (Baseboard or Electric Furnace)	3.41 HSPF2[590]		

COP_{PL} = Part Load Coefficient of Performance of efficient unit[591]

= Actual Installed

3.412 = Constant to convert the COP of the unit to the Heating Season Performance Factor (HSPF2)

ElecDHW = 1 if existing DHW is electrically heated

= 0 if existing DHW is not electrically heated

%DHWDisplaced = Percentage of total DHW load that the GSHP will provide

= Actual if known

= If unknown and if desuperheater installed, assume 44%[592]

= 0% if no desuperheater installed

EF_{ELEC} = Energy Factor (efficiency) of electric water heater

= Actual. If unknown or for new construction, assume federal standard:[593]

For <=55 gallons: 0.96 – (0.0003 * rated volume in gallons)

For >55 gallons: 2.057 – (0.00113 * rated volume in gallons)

GPD = Gallons Per Day of hot water use per person

= 45.5 gallons hot water per day per household/2.59 people per household[594]

= 17.6

Household = Average number of people per household

[587] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018' Converted to HSPF2.

[588] Based on Minimum Federal Standard effective 1/1/2023.

[589] Estimate of existing GSHP efficiency is assumed equivalent to a new baseline ASHP. It is recommended that this value be evaluated and adjusted for a future version.

[590] Electric resistance has a COP of 1.0 which equals 1/0.293 = 3.41 HSPF.

[591] As per conversations with David Buss territory manager for Connor Co, the SEER and COP ratings of an ASHP equate most appropriately with the part load EER and COP of a GSHP.

[592] Assumes that the desuperheater can provide two thirds of hot water needs for eight months of the year (2/3 * 2/3 = 44%). Based on input from Doug Dougherty, Geothermal Exchange Organization.

[593] Minimum Federal Standard as of 4/1/2015;.

Household Unit Type	Household[595]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[596]
Custom	Actual Occupancy or Number of Bedrooms[597]		

Use Multifamily if: Building meets utility's definition for multifamily

365.25 = Days per year

γWater = Specific weight of water

= 8.33 pounds per gallon

T_{OUT} = Tank temperature

= 125°F

T_{IN} = Incoming water temperature from well or municiplal system

= 50.7°F [598]

1.0 = Heat Capacity of water (1 Btu/lb*°F)

3412 = Conversion from Btu to kWh

AFUEbase = Baseline Annual Fuel Utilization Efficiency Rating. For early replacement measures, use actual AFUE rating where it is possible to measure or reasonably estimate for the remaining useful life of the existing equipment (6 years for furnace, 8 years for boilers). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[599] or if unknown assume default. If unknown value is used, it should not be derated by age.

Baseline/ Existing Heating System	AFUEbase		
	Early Replacement (Remaining useful life of existing equipment)[600]	Early Replacement (Remaining measure life)	Time of Sale or New Construction
Furnace	64.4%	80%	80%
Boiler	61.6%	84%	84%

FurnaceFlag = 1 if system replaced is a gas furnace, 0 if not.

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

[595] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.
[596] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.
[597] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.
[598] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.
[599] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).
[600] Average nameplate efficiencies of all Early Replacement qualifying equipment in Ameren PY3-PY4.

For Early Replacement (1st 6 years) F_e_Exist = 3.14%[601]

For New Construction, Time of Sale and early replacement (remaining 10 years)
F_e_New = 1.88%[602]

$EF_{GAS\ EXIST}$ = Energy Factor (efficiency) of existing gas water heater

= Actual. If unknown, assume federal standard:[603]

For <=55 gallons: 0.6483 – (0.0017 * storage capacity in gallons)

For > 55 gallons 0.7897 − (0.0004 * storage capacity in gallons)

= If tank size unknown, assume 40 gallons and EF_Baseline of 0.58

3412 = Btu per kWh

%IncentiveElectric = % of total incentive paid by electric utility

= Actual

%IncentiveGas = % of total incentive paid by gas utility

= Actual

[601] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[602] New furnaces are required to have ECM fan motors installed. Comparing Eae to Ef for furnaces on the AHRI directory as above, indicates that Fe for new furnaces is on average 1.88%.

[603] Minimum Federal Standard as of 4/1/2015.

Non Fuel Switch Illustrative Examples

New Construction using ASHP baseline:

For example, a 3-ton unit with Part Load EER2 rating of 19 and Part Load COP of 4.4 with desuperheater is installed with a 50 gallon electric water heater in single family non- IQ house in Springfield:

ΔkWh = [779 * 36,000 * (1/13.4 – 1/19) / 1000] + [1708* 36,000 * (1/7.5 – 1/(4.4*3.412)) / 1000] + [1 * 0.44 * ((1/0.945 * 17.6 * 2.62 *365.25 * 8.33 * (125-50.7) * 1)/3412)]

= 617 + 4103 + 1422

= 6142 kWh

Early Replacement

For example, a 3-ton unit with Part Load EER2 rating of 19 and Part Load COP of 4.4 with desuperheater is installed in single family non-IQ house in Springfield with a 50 gallon electric water heater replacing an existing working Air Source Heat Pump with unknown efficiency ratings:

ΔkWH for remaining life of existing unit (1st 8 years):

= [779 * 36,000 * (1/9.3 - 1/19) / 1000] + [1708 * 36,000 * (1/6.8 - 1/(4.4 * 3.412)) / 1000] + [0.44 * 1 * ((1/0.945 * 17.6 * 2.62 *365.25 * 8.33 * (125-50.7) * 1)/3412)]

= 1540 + 4947 + 1422

= 7,909 kWh

ΔkWH for remaining measure life (next 17 years):

= (779 * 36,000 * (1/13.4 – 1/19) / 1000] + [1708 * 36,000 * (1/7.5 – 1/ (4.4 * 3.412)) / 1000] + [0.44 * 1 * ((1/0.945 * 17.6 * 2.62 *365.25 * 8.33 * (125-50.7) * 1)/3412)]

= 617 + 4103 + 1422

= 6142 kWh

Fuel Switch Illustrative Example

[for illustrative purposes 50:50 Incentive is used for joint programs]

New construction using gas furnace and central AC baseline:

For example, a 3-ton unit with Part Load EER2 rating of 19 and Part Load COP of 4.4 in single family non-IQ house in Springfield with a 40 gallon gas water heater is installed in place of a natural gas furnace and 3 ton Central AC unit:

SiteEnergySavings (MMBTUs) = GasHeatReplaced + FurnaceFanSavings – GSHPSiteHeatConsumed + GSHPSiteCoolingImpact + GSHPSiteWaterImpact

GasHeatReplaced = (HeatLoad * 1/$AFUE_{base}$) / 1,000,000

= (1708 * 36,000 * 1/0.8) / 1,000,000 = 76.9 MMBtu

FurnaceFanSavings = (FurnaceFlag * HeatLoad * 1/$AFUE_{base}$ * F_e_New) / 1,000,000

= (1 * 1708 * 36,000 * 1/0.8 * 0.0188) / 1,000,000

= 1.4 MMBtu

GSHPSiteHeatConsumed = (HeatLoad * 1/COP_{PL})/ 1,000,000

= (1708 * 36,000 * 1/4.4) /1,000,000 = 14.0 MMBtu

Continued on next page

Fuel Switch Illustrative Example continued

GSHPSiteCoolingImpact = (FLHcool * Capacity_GSHPcool * (1/SEER2$_{base}$ – 1/EER2$_{PL}$)/1000 * 3412)/ 1,000,000

= (779 * 36,000 * (1/13.4 – 1/19) / 1000 * 3412) /1,000,000 = 2.10 MMBtu

GSHPSiteWaterImpact$_{Gas}$ = ((%DHWDisplaced * ((1/EF$_{Gas}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 1,000,000)

= (0.44 * (1/ 0.58 * 17.6 * 2.62 *365.25 * 8.33 * (125-50.7) * 1)) / 1,000,000 = 7.9 MMBtu

SiteEnergySavings (MMBTUs) = 76.9 + 1.4 – 14.0 + 2.10 + 7.9 = 74.3 MMBtu (Measure is eligible)

Savings would be claimed as follows:

Measure supported by:	Electric Utility claims:	Gas Utility claims:
Electric utility only	74.3 * 1,000,000/3412 = 21,776 kWh	N/A
Electric and gas utility	0.5 * 74.3 * 1,000,000/3412 = 10,888 kWh	0.5 * 74.3 * 10 = 372 Therms
Gas utility only	N/A	74.3 * 10 = 743 Therms

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = (Capacity_cooling * (1/EER2base - 1/EER2$_{FL}$))/1000 * CF

Where:

EER2base = Energy Efficiency Ratio 2 of baseline unit (kBtu/kWh). For early replacment measures, the actual EER2 rating where it is possible to measure or reasonably estimate should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time.[604] If unknown, assume default provided below. If unknown value is used, it should not be derated by age.

Baseline/Existing Cooling System	EER2_base		
	Early Replacement (Remaining useful life of existing equipment)	Early Replacement (Remaining measure life)	Time of Sale or New Construction
Air Source Heat Pump	7.4 EER2[605]	9.4 EER2[606]	
Ground Source Heat Pump	11.2 EER2	11.2 EER2	
Central AC	7.4 EER2	10.6 EER2	
No central cooling	10.6 EER2[607]	10.6 EER2	

[604] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[605] Based on Opinion Dynamics and Cadmus metering study of Ameren HVAC program participants; See 'AIC HVAC Metering Study Memo FINAL 2_28_2018' Converted to EER2.

[606] Assumed consistent with the EER2 requirements in the Federal Standard for Southwest standards (in the absence of standards for Northen states).

[607] Assumes that the decision to replace existing systems includes desire to add cooling.

$EER2_{FL}$ = Full Load EER2 Efficiency of ENERGY STAR GSHP unit [608]

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)

= 72%[609]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during peak period)

= 46.6%[610]

New Construction or Time of Sale:

For example, a 3-ton unit with Full Load EER2 unit rating of 19:

ΔkW_{SSP} = (36,000 * (1/9.4 – 1/19))/1000 * 0.72

= 0.9 kW

ΔkW_{PJM} = (36,000 * (1/9.4 – 1/19))/1000 * 0.466

= 0.71 kW

Early Replacement:

For example, a 3-ton Full Load 19 EER2 unit replaces an existing working Air Source Heat Pump with unknown efficiency ratings in Marion:

ΔkW_{SSP} for remaining life of existing unit (1st 8 years):

= (36,000 * (1/7.4 – 1/19))/1000 * 0.72

= 2.14 kW

ΔkW_{SSP} for remaining measure life (next 17 years):

= (36,000 * (1/9.4 – 1/19))/1000 * 0.72

= 1.39 kW

ΔkW_{PJM} for remaining life of existing unit (1st 8 years):

= (36,000 * (1/7.4 – 1/19))/1000 * 0.466

= 1.38 kW

ΔkW_{PJM} for remaining measure life (next 17 years):

= (36,000 * (1/9.4 – 1/19))/1000 * 0.466

= 0.902 kW

FOSSIL FUEL SAVINGS

Calculation provided together with Electric Energy Savings above

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

[608] As per conversations with David Buss territory manager for Connor Co, the EER rating of an ASHP equate most appropriately with the full load EER of a GSHP.

[609] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[610] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from gas to electric.

For the purposes of forecasting load reductions due to fuel switch GSHP projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above.Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure. For Early Replacement measures, the efficiency terms of the existing unit should be used for the remaining useful life of the existing equipment (6 years for ASHP and Central AC, 6 years for furnace, 8 years for boilers or GSHP, 15 years for electric resistance), and the efficiency terms for a new baseline unit should be used for the remaining years of the measure.

ΔTherms = [Heating Consumption Replaced] + [DHW Savings if gas]

= [(HeatLoad * 1/$AFUE_{base}$) / 100,000] + [(1 – ElecDHW) * %DHWDisplaced * (1/ $EF_{GAS\ EXIST}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 100,000)]

ΔkWh = [FurnaceFanSavings] - [GSHP heating consumption] + [Cooling savings] + [DHW savings if electric]

= [FurnaceFlag * HeatLoad * 1/$AFUE_{base}$ * F_e * 0.000293] - [(HeatLoad * (1/COP_{PL} * 3.412))/1000] + [(FLHcool * Capacity_GSHPcool * (1/SEER2base - 1/$EER2_{PL}$))/1000] + [ElecDHW * %DHWDisplaced * ((1/EF_{ELEC} * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412)]

Illustrative Example of Cost Effectiveness Inputs for Fuel Switching

For example, a 3-ton unit with Part Load EER2 rating of 19 and Part Load COP of 4.4 in single family non-IQ house in Springfield with a 40-gallon gas water heater replaces an existing working natural gas furnace and 3-ton Central AC unit with unknown efficiency ratings. [Note the calculation provides the annual savings for the first 6 years of the measure life, an additional calculation (not shown) would be required to calculate the annual savings for the remaining life (years 7-25)]:

ΔTherms = [(HeatLoad * 1/$AFUE_{exist}$) / 100,000] + [(1 – ElecDHW) * %DHWDisplaced * (1/ $EF_{GAS\ EXIST}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 100,067)]

= [1708 * 36,000 * 1/0.644) / 100,000] + [((1 – 0) * 0.44 * (1/ 0.58 * 17.6 * 2.62 *365.25 * 8.33 * (125-54) * 1) / 100,067)]

= 955 + 76

= 1031 therms

ΔkWh = [FurnaceFlag * HeatLoad * 1/$AFUE_{base}$ * F_e_Exist * 0.000293] - [(HeatLoad * (1/COP_{PL} * 3.412))/1000] + [(FLHcool * Capacity_GSHPcool * (1/SEERexist - 1/EER_{PL}))/1000] + [ElecDHW * %DHWDisplaced * (((1/EF_{ELEC}) * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412)]

= [1 * 1708 * 3600 * 1/0.644 * 0.0314 * 0.000293] - [(1708 * 36,000 * (1/(4.4 * 3.412)))/ 1000] + [(779 * 36,000 * (1/9.2 - 1/19))/ 1000)] + [0 * 0.44 * (((1/0.904) * 17.6 * 2.62 *365.25 * 8.33 * (125-50.7) * 1)/3412)]

= 88 - 4096 + 1572 + 0

MEASURE CODE: RS-HVC-GSHP-V16-260101

REVIEW DEADLINE: 1/1/2027

5.3.9 High Efficiency Bathroom Exhaust or Radon Mitigation Fan

DESCRIPTION

This market opportunity measure is split into the purchase of a new bathroom fan for typical usage, meet the need for continuous mechanical ventilation due to reduced air-infiltration from a tighter building shell, and for Radon mitigation. In retrofit projects, existing fans may be too loud, or insufficient in other ways, to be operated as required. This measure assumes fan capacities between 10 and 200 CFM rated at a sound level of less than 2.0 sones at 0.1 inches of water column static pressure, or 50 CFM if used for continuous ventilation, or 120 CFM for Radon mitigation. All eligible installations shall be sized to provide the mechanical ventilation rate indicated by ASHRAE 62.2 or for Radon mitigation.

This measure was developed to be applicable to the following program types: TOS, NC, RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

New efficient ENERGY STAR[611] or ENERGY STAR Most Efficient exhaust-only ventilation fan, quiet (< 2.0 sones) operating in accordance with recommended ventilation rate indicated by ASHRAE 62.2 – 2016 or for Radon mitigation. ENERGY STAR specifications (effective October 1, 2015) and 2018 Most Efficient specifications are provided below:

Efficiency Level	Fan Capacity	Minimum Efficacy Level (CFM/Watts)	Maximum Allowable Sound Level (sones)
ENERGY STAR	10 – 89 CFM	2.8	2.0
	90 – 200 CFM	3.5	
ENERGY STAR Most Efficient	All	10	
ENERGY STAR (In-Line)	All	3.8	

DEFINITION OF BASELINE EQUIPMENT

New standard efficiency exhaust-only ventilation fan.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 19 years.[612]

DEEMED MEASURE COST

Incremental cost per installed fan is $48 for ENERGY STAR qualified fans.[613]

LOADSHAPE

Loadshape R11 - Residential Ventilation

COINCIDENCE FACTOR

The summer Peak Coincidence Factor is assumed to be 100% because the fan runs continuously.

[611] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[612] Conservative estimate based upon GDS Associates Measure Life Report "Residential and C&I Lighting and HVAC measures" 25 years for whole-house fans, and 19 for thermostatically-controlled attic fans.
[613] VEIC analysis using cost data collected from wholesale and retail vendors.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (CFM * (1/\eta_{,BASELINE} - 1/\eta_{EFFICIENT})/1000) * Hours$$

Where:

CFM = Nominal Capacity of the exhaust fan
= Actual or use defaults provided below
= Assume 50CFM for continuous ventilation[614]

$\eta_{BASELINE}$ = Average efficacy for baseline fan (CFM/watts)
= See table below

$\eta_{EFFCIENT}$ = Average efficacy for efficient fan (CFM/watts)
= Actual or use defaults provided below

Hours = assumed annual run hours,
= 1089 for standard usage[615]
= 8766 for continuous ventilation.

Defaults provided below:[616]

					ENERGY STAR		ENERGY STAR Most Efficient	
Application	Min CFM	Max CFM	Average CFM	Base CFM/Watts	CFM/Watts	ΔkWh Savings	CFM/Watts	ΔkWh Savings
Standard usage	10	89	71.0	1.7	4.7	28.9	11.9	38.9
	90	200	115.9	2.7	5.4	23.1	14.2	37.8
	Unknown		94.2	2.2	5.1	26.9	13.3	39.4
Continuous usage	N/A		50	1.7	5.0	164.6	11.3	213.8
Continuous usage (Radon)	N/A		120	2.5	5.0	203.2	n/a	n/a

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (CFM * (1/\eta_{BASELINE} - 1/_{EFFICIENT})/1000) * CF$$

Where:

[614] 50CFM is the closest available fan size to ASHRAE 62.2 Section 4.1 Whole House Ventilation rates based upon typical square footage and bedrooms.
[615] Assumed to be consistent with Residential Indoor Lighting hours of use.
[616] Based on review of Bathroom Exhaust Fan product available on CEC Appliance Database, accessed 4/6/2023. See 'CEC-res-vent-fans-4.6.23.xlsx' for more information.

CF = Summer Peak Coincidence Factor

= 0.135 for standard usage

= 1.0 for continuous operation

Other variables as defined above

Application	Min CFM	Max CFM	Average CFM	ENERGY STAR ΔkW Savings	ENERGY STAR Most Efficient ΔkW Savings
Standard usage	10	89	70.6	0.0036	0.0048

5.3.10 HVAC Tune Up (Central Air Conditioning or Air Source Heat Pump)

DESCRIPTION

This measure involves the measurement of refrigerant charge levels and airflow over the central air conditioning or heat pump unit coil, correction of any problems found and post-treatment re-measurement. Measurements must be performed with standard industry tools and the results tracked by the efficiency program.

Savings from this measure are developed using a reputable Wisconsin study. It is recommended that future evaluation be conducted in Illinois to generate a more locally appropriate characterization.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

For tune-up of central systems in multifamily buildings, use Volume 2 Commercial and Industrial Measures.

DEFINITION OF EFFICIENT EQUIPMENT

N/A

DEFINITION OF BASELINE EQUIPMENT

This measure assumes that the existing unit being maintained is either a residential central air conditioning unit or an air source heat pump that has not been serviced for at least 3 years.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 3 years.[617]

DEEMED MEASURE COST

If the implementation mechanism involves delivering and paying for the tune up service, the actual cost should be used. If however the customer is provided a rebate and the program relies on private contractors performing the work, the measure cost should be assumed to be $250.[618]

LOADSHAPE

Loadshape R08 - Residential Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[619]

CF_{SSP} = Summer System Peak Coincidence Factor for Heat Pumps (during system peak hour)

= 72%[620]

[617] Based on DEER 2014 EUL Table for "Clean Condenser Coils – Residential" and "Refrigerant Charge – Residential".
[618] Based on personal communication with HVAC efficiency program consultant Buck Taylor or Roltay Inc., 6/21/10, who estimated the cost of tune up at $125 to $225, depending on the market and the implementation details. The average value of $175 has been increased by inflation to give an estimate of $250 in 2026.
[619] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[620] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[621]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$\Delta kWh_{Central\ AC}$ = (FLHcool * Capacity_cooling* (1/$SEER2_{CAC}$))/1,000 * MFe

$\Delta kWh_{Air\ Source\ Heat\ Pump}$ = ((FLHcool * Capacity_cooling * (1/$SEER2_{ASHP}$))/1,000 * MFe) + (FLHheat * Capacity_heating * (1/$HSPF2_{ASHP}$))/1,000 * MFe)

Where:

FLHcool = Full load cooling hours

Dependent on location as below:[622]

Climate Zone (City based upon)	FLHcool Single Family	FLHcool Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1,082	982
5 (Marion)	956	868
Weighted Average[623] ComEd Ameren Statewide	 676 875 731	 603 791 655

Use Multifamily if: Building meets utility's definition for multifamily and system serves single unit. For residential sized systems serving 2 or more units, assume single family hours. For central systems use Volume 2 Commercial and Industrial Measures.

Capacity_cooling = Cooling cpacity of equipment in Btu/hr (note 1 ton = 12,000 Btu/hr)

= Actual

$SEER2_{CAC}$ = SEER2 Efficiency of existing central air conditioning unit receiving maintenence * Distribution Efficiency

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency if only equipment efficiency is available). If unknown assume 9.5 SEER2 [624] * 0.85 = 8.1 SEER2

MFe = Maintenance energy savings factor

[621] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[622] Based on Full Load Hours from ENERGY STAR with adjustments made in a Navigant Evaluation, other cities were scaled using those results and CDD. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[623] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[624] Use actual SEER2 rating where it is possible to measure or reasonably estimate. Unknown default of 9.5 SEER2 is a VEIC estimate of existing unit efficiency, based on minimum federal standard between the years of 1992 and 2006, converted to SEER2.

= 0.05[625]

$SEER2_{ASHP}$ = SEER2 Efficiency of existing air source heat pump unit receiving maintenence* Distribution Efficiency

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for ducted system if only equipment efficiency is available). If unknown assume 9.5 SEER2 [626] * 0.85 = 8.1 SEER2

FLHheat = Full load heating hours

Dependent on location:[627]

Climate Zone (City based upon)	FLHheat
1 (Rockford)	1924
2 (Chicago)	1726
3 (Springfield)	1708
4 (Belleville)	1195
5 (Marion)	1270
Weighted Average[628]	
ComEd	1766
Ameren	1547
Statewide	1700

Capacity_heating = Heating cpacity of equipment in Btu/hr (note 1 ton = 12,000 Btu/hr)

= Actual

$HSPF2_{ASHP}$ = Heating Season Performance Factor of existing air source heat pump unit receiving maintenence * Distribution Efficiency

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency if only equipment efficiency is available). If unknown assume 5.8 HSPF2 [629] * 0.85 = 4.9 HSPF2

[626] Use actual SEER2 rating where it is possible to measure or reasonably estimate. Unknown default of 9.5 SEER2 is a VEIC estimate of existing unit efficiency, based on minimum federal standard between the years of 1992 and 2006, converted to SEER2.

[627] Full load heating hours for heat pumps are provided for Rockford, Chicago and Springfield in the ENERGY STARCalculator. Estimates for the other locations were calculated based on the FLH to Heating Degree Day (from NCDC) ratio. VEIC consider ENERGY STARestimates to be high due to oversizing not being adequately addressed. Using average Illinois billing data (from Illinois Commerce Commission) VEIC estimated the average gas heating load and used this to estimate the average home heating output (using 83% average gas heat efficiency). Dividing this by a typical 36,000 Btu/hr ASHP gives an estimate of average ASHP FLH_heat of 1821 hours. We used the ratio of this value to the average of the locations using the ENERGY STAR data (1994 hours) to scale down the ENERGY STAR estimates. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[628] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[629] Use actual HSPF2 rating where it is possible to measure or reasonably estimate. Unknown default of 5.8 HSPF2 is a VEIC estimate based on minimum Federal Standard between 1992 and 2006, converted to HSPF2.

For example, maintenance of a 3-ton, SEER2 10 air conditioning unit in a single family house in Springfield:

ΔkWh_{CAC} = (779 * 36,000 * (1/10))/1,000 * 0.05

= 140 kWh

For example, maintenance of a 3-ton, SEER2 10, HSPF2 6.8 air source heat pump unit in a single family house in Springfield:

ΔkWh_{ASHP} = ((779 * 36,000 * (1/10))/1,000 * 0.05) + (1,708 * 36,000 * (1/6.8))/1,000 * 0.05)

= 592 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = Capacity_cooling * (1/EER2)/1,000 * MFd * CF

Where:

EER2 = EER2 Efficiency of existing unit receiving maintenance in Btu/H/Watts

= Calculate using Actual SEER2

= - 0.02*SEER2^2 + 1.12*SEER2 [630]

MFd = Maintenance demand savings factor

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)

= 68%[631]

CF_{SSP} = Summer System Peak Coincidence Factor for Heat Pumps (during system peak hour)

= 72%[632]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C and Heat Pumps (average during peak period)

= 46.6%[633]

For example, maintenance of 3-ton, SEER2 10 (equals EER2 9.2) CAC unit:

ΔkW_{SSP} = 36,000 * 1/(9.2)/1,000 * 0.02 * 0.68

= 0.0532 kW

ΔkW_{PJM} = 36,000 * 1/(9.2)/1,000 * 0.02 * 0.466

= 0.0365 kW

5.3.11 Programmable Thermostats

DESCRIPTION

This measure characterizes the household energy savings from the installation of a new or reprogramming of an existing Programmable Thermostat for reduced heating energy consumption through temperature set-back during unoccupied or reduced demand times. Because a literature review was not conclusive in providing a defensible source of prescriptive cooling savings from programmable thermostats, cooling savings from programmable thermostats are assumed to be zero for this version of the measure. It is not appropriate to assume a similar pattern of savings from setting a thermostat down during the heating season and up during the cooling season. Since energy savings are applicable at the household level, savings should only be claimed for one thermostat of any type (i.e., one programmable thermostat or one advanced thermostat), installation of multiple thermostats per home does not accrue additional savings.

This measure was developed to be applicable to the following program types: TOS, NC, RF, DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The criteria for this measure are established by replacement of a manual-only temperature control, with one that has the capability to adjust temperature setpoints according to a schedule without manual intervention. This category of equipment is broad and rapidly advancing in regards to the capability, and usability of the controls and their sophistication in setpoint adjustment and information display, but for the purposes of this characterization, eligibility is perhaps most simply defined by what it is not: a manual only temperature control.

For the thermostat reprogramming measure, the auditor consults with the homeowner to determine an appropriate set back schedule, reprograms the thermostat and educates the homeowner on its appropriate use.

DEFINITION OF BASELINE EQUIPMENT

For new thermostats the baseline is a non-programmable thermostat requiring manual intervention to change temperature setpoint.

For the purpose of thermostat reprogramming, an existing programmable thermostat that an auditor determines is being used in override mode or otherwise effectively being operated like a manual thermostat.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life of a programmable thermostat is assumed to be 16 years, however concerns over persistence over a population result in the application of a mid-life adjustment to reduce annual savings during the measure lifetime.[634] For reprogramming, the measure life of 2 years is assumed.

DEEMED MEASURE COST

Actual material and labor costs should be used if the implementation method allows. If unknown (e.g., through a retail program) the capital cost for the new installation measure is assumed to be $30.[635] The cost for reprogramming is assumed to be $10 to account for the auditor's time to reprogram and educate the homeowner.

LOADSHAPE

Loadshape R09 - Residential Electric Space Heat

[634] ASHRAE Applications (2003), Section 36, Table 3 provides an estimate of 16 years for the equipment life, however the TAC agreed to reduce by 50% to account for persistence issues. This is applied via a midlife adjustment (see later section) rather than a reduction in the measure life to 8 years.

[635] Market prices vary significantly in this category, generally increasing with thermostat capability and sophistication. The basic functions required by this measure's eligibility criteria are available on units readily available in the market for the listed price.

COINCIDENCE FACTOR

N/A due to no savings attributable to cooling during the summer peak period.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

ΔkWh[636] = $\Delta kWh_heatingElectric + \Delta kWh_heatingFurnace$

Where:

$\Delta kWh_heatingElectric$ = %ElectricHeat * Elec_Heating_Consumption * Heating_Reduction * HF * Eff_ISR

%ElectricHeat = Percentage of heating savings assumed to be electric

Heating fuel	%ElectricHeat
Electric	100%
Natural Gas	0%
Unknown	3%[637]

Elec_Heating_ Consumption = Estimate of annual household heating consumption for electrically heated homes.[638] If location and heating type is unknown, assume 15,683 kWh.[639]

Climate Zone (City based upon)	Electric Resistance (Baseboard or Electric Furnace) Elec_Heating_ Consumption (kWh)	Electric Heat Pump Elec_Heating_ Consumption (kWh)
1 (Rockford)	21,748	12,793
2 (Chicago)	20,777	12,222
3 (Springfield)	17,794	10,467
4 (Belleville)	13,726	8,074
5 (Marion)	13,970	8,218
Average	19,749	11,617

Heating_Reduction = Assumed percentage reduction in total household heating energy consumption due to programmable thermostat

[636] Note the second part of the algorithm relates to furnace fan savings if the heating system is Natural Gas.
[637] Value used is based on known PY8 percent of electric heat provided by Navigant as part of the ongoing evaluation work source: "Slide 21: May 22, 2018, Second Addendum IL TRM Advanced Thermostat Cooling Savings Evaluation"
[638] Values in table are based on converting an average household heating load (834 therms) for Chicago based on 'Table E-1, Energy Efficiency/Demand Response Nicor Gas Plan Year 1: Research Report: Furnace Metering Study, Draft, Navigant, August 1 2013 to an electric heat load (divide by 0.03412) to electric resistance and ASHP heat load (resistance load reduced by 15% to account for distribution losses that occur in furnace heating but not in electric resistance while ASHP heat is assumed to suffer from similar distribution losses) and then to electric consumption assuming efficiencies of 100% for resistance and 200% for HP (see 'Household Heating Load Summary Calculations_08222018.xls'). Finally these values were adjusted to a statewide average using relative HDD assumptions to adjust for the evaluation results focus on northern region. Values for individual cities are then calculated by comparing average HDD to the individual city's HDD.
[639] Assumption that 1/2 of electrically heated homes have electric resistance and 1/2 have Heat Pump, based on 2010 Residential Energy Consumption Survey for Illinois.

= 6.2%[640]

HF = Household factor, to adjust heating consumption for non-single-family households.

Household Type	HF
Single-Family	100%
Mobile home	83%[641]
Multifamily	65%[642]
Unknown	96.5%[643]
Actual	Custom[644]

Use Multifamily if: Building meets utility's definition for multifamily and system serves single unit. For residential sized systems serving 2 or more units, assume single family hours. For central systems use Volume 2 Commercial and Industrial Measures.

Eff_ISR = Effective In-Service Rate, the percentage of thermostats installed and programmed effectively

Program Delivery	Eff_ISR
Direct Install	100%
Other, or unknown	56%[645]

ΔkWh_heatingFurnace = If *furnace* (fossil fueled or electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = ΔTherms * F_e * 29.3

If electric furnace: = ΔkWh_heatingElectric * F_e

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[646]

29.3 = kWh per therm

[640] The savings from programmable thermostats are highly susceptible to many factors best addressed, so far for this category, by a study that controlled for the most significant issues with a very large sample size. To the extent that the treatment group is representative of the program participants for IL, this value is suitable. Higher and lower values would be justified based upon clear dissimilarities due to program and product attributes. Future evaluation work should assess program specific impacts associated with penetration rates, baseline levels, persistence, and other factors which this value represents.

[641] Since mobile homes are similar to Multifamily homes with respect to conditioned floor area but to single-family homes with respect to exposure (i.e., all four wall orientations are adjacent to the outside), this factor is estimated as an average of the single family and multifamily household factors.

[642] Multifamily household heating consumption relative to single-family households is affected by overall household square footage and exposure to the exterior. This 65% factor is applied to MF homes based on professional judgment that average household size, and heat loads of MF households are smaller than single-family homes

[643] When Household type is unknown, a value of 96.5% may be used as a weighted average of 90% SF and 10% MF (96.5% = 100%*90% + 65%*10%) based on a Navigant evaluation of PY8 participants in ComEd's advanced thermostat program.

[644] Program-specific household factors may be utilized on the basis of sufficiently validated program evaluations.

[645]"Programmable Thermostats. Report to KeySpan Energy Delivery on Energy Savings and Cost Effectiveness," GDS Associates, Marietta, GA. 2002GDS

[646] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

For example, a programmable thermostat direct-installed in an electric resistance heated, single-family home in Springfield:

ΔkWH = 1 * 17,794 * 0.062 * 100% * 100% + (0 * 0.0314 * 29.3)

= 1,103 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A due to no savings from cooling during the summer peak period.

NATURAL GAS ENERGY SAVINGS

ΔTherms = %FossilHeat * Gas_Heating_Consumption * Heating_Reduction * HF * Eff_ISR

Where:

%FossilHeat = Percentage of heating savings assumed to be Natural Gas

Heating fuel	%FossilHeat
Electric	0%
Natural Gas	100%
Unknown	97%[647]

Gas_Heating_Consumption

= Estimate of annual household heating consumption for gas heated single-family homes. If location is unknown, assume the average below:[648]

Climate Zone (City based upon)	Gas_Heating_ Consumption (therms)
1 (Rockford)	1,052
2 (Chicago)	1,005
3 (Springfield)	861
4 (Belleville)	664
5 (Marion)	676
Average	955

For example, a programmable thermostat directly-installed in a gas heated single-family home in Chicago:

ΔTherms = 1.0 * 1005 * 0.062 * 100% * 100%

= 62.3 therms

Mid-Life Baseline Adjustment

[647] Value used is based on known PY8 percent of electric heat provided by Navigant as part of the ongoing evaluation work source: "Slide 21: May 22, 2018, Second Addendum IL TRM Advanced Thermostat Cooling Savings Evaluation"

[648] Values are based on adjusting the average household heating load (834 therms) for Chicago based on 'Table E-1, Energy Efficiency / Demand Response Nicor Gas Plan Year 1, Research Report: Furnace Metering Study', divided by standard assumption of existing unit efficiency of 83% (estimate based on 24% of furnaces purchased in Illinois were condensing in 2000 (based on data from GAMA, provided to Department of Energy), assuming typical efficiencies: (0.24*0.92) + (0.76*0.8) = 0.83) to give 1005 therms. This Chicago value was then adjusted to a statewide average using relative HDD assumptions to adjust for the evaluation results focus on northern region. Values for individual cities are then calculated by comparing average HDD to the individual city's HDD.

Due to concerns that across a population the savings for programmable thermostats are likely to decline through the technical lifetime of the thermostat,[649] a mid-life adjustment should be applied. The mid-life adjustment should be applied in year 6 (i.e., after five years of full savings) and is calculated as 28%. This results in a consistent lifetime savings as applying a 50% reduction to the technical lifetime. This adjustment should be applied to both electric and therm heating savings.

MEASURE CODE: RS-HVC-PROG-V10-260101

REVIEW DEADLINE: 1/1/2029

[649] This concern is based on consideration of the findings from a number of evaluations, including Sachs et al, *"Field Evaluation of Programmable Thermostats",* US DOW Building Technologies Program, December 2012, p35; "low proportion of households that ended up using thermostat-enabled energy saving settings", and Meier et al., *"Usability of residential thermostats: Preliminary investigations",* Lawrence Berkeley National Laboratory, March 2011, p1; "The majority of occupants operated thermostats manually, rather than relying on their programmable features and almost 90% of respondents reported that they rarely or never adjusted the thermostat to set a weekend or weekday program. Photographs of thermostats were collected in one on-line survey, which revealed that about 20% of the thermostats displayed the wrong time and that about 50% of the respondents set their programmable thermostats on "long term hold" (or its equivalent)."

5.3.12 Ductless Heat Pumps – Removed in v12

Measure now combined with 5.3.1 Air Source Heat Pump (Centrally Ducted and Ductless)

5.3.13 Residential Furnace Tune-Up

DESCRIPTION

This measure is for a natural gas Residential furnace that provides space heating. The tune-up will improve furnace performance by inspecting, cleaning and adjusting the furnace and appurtenances for correct and efficient operation. Additional savings maybe realized through a complete system tune-up.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure an approved technician must complete the tune-up requirements listed below:[650]

- Measure combustion efficiency using an electronic flue gas analyzer
- Check and clean blower assembly and components per manufacturer's recommendations
- Where applicable Lubricate motor and inspect and replace fan belt if required
- Inspect for gas leaks
- Clean burner per manufacturer's recommendations and adjust as needed
- Check ignition system and safety systems and clean and adjust as needed
- Check and clean heat exchanger per manufacturer's recommendations
- Inspect exhaust/flue for proper attachment and operation
- Inspect control box, wiring and controls for proper connections and performance
- Check air filter and clean or replace per manufacturer's
- Inspect duct work connected to furnace for leaks or blockages
- Measure temperature rise and adjust flow as needed
- Check for correct line and load volts/amps
- Check thermostat operation is per manufacturer's recommendations(if adjustments made, refer to 'Residential Programmable Thermostat' measure for savings estimate)
- Perform Carbon Monoxide test and adjust heating system until results are within standard industry acceptable limits

DEFINITION OF BASELINE EQUIPMENT

The baseline is furnace assumed not to have had a tune-up in the past 3 years.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for the clean and check tune up is 3 years.[651]

DEEMED MEASURE COST

The incremental cost for this measure should be the actual cost of tune up.

DEEMED O&M COST ADJUSTMENTS

There are no expected O&M savings associated with this measure.

LOADSHAPE

Loadshape R09 - Residential Electric Space Heat

[650] American Standard Maintenance for Indoor Units (see 'HVAC Maintenance American Standard')

5.3.14 Boiler Reset Controls

DESCRIPTION

This measure relates to improving system efficiency by adding controls to residential heating boilers to vary the boiler entering water temperature relative to heating load as a function of the outdoor air temperature to save energy. The water can be run a little cooler during fall and spring, and a little hotter during the coldest parts of the winter. A boiler reset control has two temperature sensors - one outside the house and one in the boiler water. As the outdoor temperature goes up and down, the control adjusts the water temperature setting to the lowest setting that is meeting the house heating demand. There are also limits in the controls to keep a boiler from operating outside of its safe performance range.[655]

This measure was developed to be applicable to the following program types: RF.

DEFINITION OF EFFICIENT EQUIPMENT

Natural gas single family residential customer adding boiler reset controls capable of resetting the boiler supply water temperature in an inverse fashion with outdoor air temperature. The system must be set so that the minimum temperature is not more than 10 degrees above manufacturer's recommended minimum return temperature. This boiler reset measure is limited to existing condensing boilers serving a single family residence. Boiler reset controls for non-condensing boilers in single family residences should be implemented as a custom measure, and the cost-effectiveness should be confirmed.

DEFINITION OF BASELINE EQUIPMENT

Existing condensing boiler in a single family residential setting without boiler reset controls.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The life of this measure is 16 years, which is assumed to be the remaining life of the existing boiler.[656]

DEEMED MEASURE COST

The cost of this measure is $612.[657]

LOADSHAPE

COINCIDENCE FACTOR

N/A

Algorithm

[655] Energy Solutions Center, a consortium of natural gas utilities, equipment manufacturers and vendors, See 'Boiler Reset Control – NaturalGasEfficiency.org'.
[656] This is intentionally longer than the assumptions found in the early replacement residential HVAC measures as the application of boiler reset controls will occur in a variety of homes that will not be targeted for early replacement HVAC systems.
[657] Nexant. Questar DSM Market Characterization Report. August 9, 2006.

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

N/A

SUMMER COINCIDENT PEAK DEMAND SAVINGS

NA

FOSSIL FUEL SAVINGS

ΔTherms = Gas_Boiler_Load * (1/AFUE) * Savings Factor

Where:

Gas_Boiler_Load[658]

= Estimate of annual household Load for gas boiler heated single-family homes. If location is unknown, assume the average below.[659]

= or Actual if informed by site-specific load calculations, ACCA Manual J, or equivalent.[660]

Climate Zone (City based upon)	Gas_Boiler Load (therms)
1 (Rockford)	1275
2 (Chicago)	1218
3 (Springfield)	1043
4 (Belleville)	805
5 (Marion)	819
Average	1158

AFUE = Existing Condensing Boiler Annual Fuel Utilization Efficiency Rating

= Actual. If unknown, default to 90%.[661]

SF = Savings Factor, 5%[662]

[658] Boiler consumption values are informed by an evaluation which did not identify any fraction of heating load due to domestic hot water (DHW) provided by the boiler. Thus these values are an average of both homes with boilers only providing heat, and homes with boilers that also provide DHW. Heating load is used to describe the household heating need, which is equal to (gas heating consumption * AFUE)

[659] Values are based on household heating consumption values and inferred average AFUE results from Table 3-4, Program Sample Analysis, *Nicor R29 Res Rebate Evaluation Report 092611_REV FINAL to Nicor*). Adjusting to a statewide average using relative HDD values to adjust for the evaluation results focus on northern region. Values for individual cities are then calculated by comparing average HDD to the individual city's HDD.

[660] The Air Conditioning Contractors of America Manual J, Residential Load Calculation 8th Edition produces equipment sizing loads for Single Family, Multi-single, and Condominiums using input characteristics of the home. A best practice for equipment selection and installation of Heating and Air Conditioning, load calculations should be completed by contractors during the selection process and may be readily available for program data purposes.

[661] Condensing boilers typically have an AFUE greater than 90%. This is also a consistent assumption with the '5.3.6 High Efficiency Boiler' measure.

[662] Energy Solutions Center, a consortium of natural gas utilities, equipment manufacturers and vendors. See 'Boiler Reset Control – NaturalGasEfficiency.org'. This savings value is also supported by Cadmus impact evaluation for the Electric and Gas Program Administrators of Massachusetts: Cadmus, Home Energy Services Impact Evaluation, August 2012.

For example, boiler reset controls on a 92.5 AFUE boiler at a household in Rockford, IL

ΔTherms = 1275 * (1/0.925) * 0.05

= 69 Therms

5.3.15 ENERGY STAR Ceiling Fan

DESCRIPTION

A ceiling fan/light unit meeting the efficiency specifications of ENERGY STAR[663] version 4.0 is installed in place of a model meeting the federal standard. ENERGY STAR qualified ceiling fan/light combination units are over 60% more efficient than conventional fan/light units and use improved motors and blade designs.

Due to the savings from this measure being derived from more efficient ventilation and more efficient lighting, and the loadshape and measure life for each component being very different, the savings are split into the component parts and should be claimed together. Lighting savings should be estimated utilizing the 5.5.9 LED Fixtures measure.

This measure was developed to be applicable to the following program types: TOS, NC, RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as an ENERGY STAR certified ceiling fan with integral LED bulbs.[664] Concurrently, ENERGY STAR criteria require ceiling fans with light kits to provide the consumer with LEDs. In the cases where light kits require screw-base sockets, the efficient lamps have to be included in the packaging of the ceiling fan.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be a standard fan with efficient incandescent or halogen light bulbs. Production of 100W, standard efficacy incandescent lamps ended in 2012 followed by restrictions on 75W in 2013 and 60W and 40W in 2014, due to the Energy Independence and Security Act of 2007 (EISA). Finally, a provision in the EISA regulations requires that by January 1, 2020, all lamps meet efficiency criteria of at least 45 lumens per watt, in essence making the baseline equivalent to a current day CFL. Therefore the measure life (number of years that savings should be claimed) for the lighting portion of the savings should be reduced once the assumed lifetime of the bulb exceeds 2020. Due to expected delay in clearing retail inventory and to account for the operating life of a halogen incandescent potentially spanning over 2020, this shift is assumed not to occur until 2021.

Effective January 21, 2020, all ceiling fan light kits manufactured after this date must be packaged with lamps to fill all screw-base sockets, further limiting the potential for inefficient light bulbs to be utilized. Additionally, ceiling fan light kits with pin-based sockets for fluorescent lamps must use electronic ballasts. Integrated ceiling fan light kits must adhere to the same lighting efficiency requirements.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The fan savings measure life is assumed to be 10 years.[665]

The lighting savings measure life is assumed to be 1 year for lighting savings for units installed in 2020 (see 5.5.9 LED Fixtures measure).[666]

DEEMED MEASURE COST

Incremental cost of a ceiling fan with light kit is $46.

Incremental cost of only a ceiling fan is $30.71. [667]

[663] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[664] ENERGY STAR version 4.0, Product Specification for Residential Ceiling Fans and Ceiling Fan Light Kits, effective June 15, 2018.
[665] Lifetime estimate is sourced from the ENERGY STAR Ceiling Fan Savings Calculator.
[666] Since the replacement baseline bulb from 2020 on will be equivalent to a CFL, no additional savings should be claimed from that point. Due to expected delay in clearing stock from retail outlets and to account for the operating life of a halogen incandescent potentially spanning over 2020, this shift is assumed not to occur until 2021.
[667] The incremental cost of $46 is sourced from the ENERGY STAR Ceiling Fan Savings Calculator, which is based on a ceiling fan

LOADSHAPE

R06 - Residential Indoor Lighting

R11 - Residential Ventilation

COINCIDENCE FACTOR

The summer peak coincidence factor for the ventilation savings is assumed to be 30%.[668]

For lighting savings, see 5.5.9 LED Fixtures measure.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$\Delta kWh = \Delta kWh_{fan} + \Delta kWh_{Light}$

ΔkWh_{fan} = [Days * FanHours * (($\%Low_{base}$ * $WattsLow_{base}$) + ($\%Med_{base}$ * $WattsMed_{base}$) + ($\%High_{base}$ * $WattsHigh_{base}$))/1000] - [Days * FanHours * (($\%Low_{ES}$ * $WattsLow_{ES}$) + ($\%Med_{ES}$ * $WattsMed_{ES}$) + ($\%High_{ES}$ * $WattsHigh_{ES}$))/1000]

ΔkWh_{light} = see 5.5.9 LED Fixtures measure.

Where:[669]

Days = Days used per year

= Actual. If unknown use 365.25 days/year

FanHours = Daily Fan "On Hours"

= Actual. If unknown use 3 hours

$\%Low_{base}$ = Percent of time spent at Low speed of baseline

= 40%

$WattsLow_{base}$ = Fan wattage at Low speed of baseline

= Actual. If unknown use 15 watts

$\%Med_{base}$ = Percent of time spent at Medium speed of baseline

= 40%

$WattsMed_{base}$ = Fan wattage at Medium speed of baseline

= Actual. If unknown use 34 watts

$\%High_{base}$ = Percent of time spent at High speed of baseline

and a light kit. In order to determine the incremental cost of only a ceiling fan, the incremental cost of the lights were factored in and removed accordingly. Through review of the ENERGY STAR Qualified Products List, accessed on October 11, 2018, the average ceiling fan LED light kit had 1.2 lamps, with an average wattage of 11.8W. The comparable baseline wattage, baseline cost, and efficient lamp cost is based on a scaled equivalence from the 5.5.9 LED Fixtures measure.

[668] Assuming that the CF same as a Room AC. Consistent with coincidence factors found in: RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008.

[669] All fan operating conditions and baseline default assumptions are based upon assumptions provided in the ENERGY STAR Ceiling Fan Savings Calculator. The efficient wattages at the low and high speed settings are sourced from the average of available products on the ENERGY STAR Qualified Products List (QPL), as pulled on 5/9/2025. The efficient wattage at the medium speed is interpolated based on the varying speed wattages from the ENERGY STAR version 4.0 specifications. For more information on the QPL data set, please see "Illinois Residential Ceiling Fan Analysis_2025.xlsx".

= 20%

$WattsHigh_{base}$ = Fan wattage at High speed of baseline

= Actual. If unknown use 67 watts

%LowES = Percent of time spent at Low speed of ENERGY STAR

= 40%

$WattsLow_{ES}$ = Fan wattage at Low speed of ENERGY STAR

= Actual. If unknown use 5 watts

$\%Med_{ES}$ = Percent of time spent at Medium speed of ENERGY STAR

= 40%

$WattsMed_{ES}$ = Fan wattage at Medium speed of ENERGY STAR

= Actual. If unknown use 16 watts

$\%High_{ES}$ = Percent of time spent at High speed of ENERGY STAR

= 20%

$WattsHigh_{ES}$ = Fan wattage at High speed of ENERGY STAR

= Actual. If unknown use 36 watts

For ease of reference, the fan assumptions are provided below in table form:

	Low Speed	Medium Speed	High Speed
Percent of Time at Given Speed	40%	40%	20%
Conventional Unit Wattage	15	34	67
ENERGY STAR Unit Wattage	5	16	36
ΔW	10	18	31

If the lighting WattsBase and WattsEE is unknown, assume the following:[670]

WattsBase = 1.2 x 46.5 = 55.8 W

WattsEE = 1.2 x 17.3 = 20.1 W

For example, an ENERGY STAR ceiling fan with one, 22.4W LED lamp as part of its light kit were purchased and installed to replace an existing ceiling fan that was no longer operational, the savings are:

ΔkWh_{fan} = [365.25*3*((0.4*15)+(0.4*34)+(0.2*67))/1000] – [365.25*3*((0.4*5)+(0.4*16)+(0.2*36))/1000]

= 36.2 – 17.1 = 19.1 kWh

ΔkWh_{light} =((88.5 – 22.4)/1000) *759 * 1.06

= 53.2 kWh

ΔkWh = 19.1+53.2

= 72.3 kWh

[670] Through review of the ENERGY STAR Qualified Products List, accessed on May 5, 2022, the average ceiling fan LED light kit had 1.2 lamps, with an average wattage of 17.3 W. The comparable baseline is based on a scaled equivalent wattage from the 5.5.9 LED Fixtures measure.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$\Delta kW = \Delta kW_{Fan} + \Delta kW_{light}$

$\Delta kW_{Fan} = ((WattsHigh_{base} - WattsHigh_{ES})/1000) * CF_{fan}$

ΔkW_{Light} = see 5.5.9 LED Fixtures measure.

Where:

CF_{fan} = Summer Peak coincidence factor for ventilation savings

= 30%[671]

CF_{light} = Summer Peak coincidence factor for lighting savings

= 11.9%[672]

For example, an ENERGY STAR ceiling fan with one 22.4W LED lamp as part of its light kit were purchased and installed to replace an existing ceiling fan that was no longer operational, the savings are:

ΔkW_{fan} = ((67-36)/1000) * 0.3

= 0.0093 kW

ΔkW_{light} =((88.5 – 22.4)/1000) * 1.11 * 0.071

= 0.0052 kW

ΔkW = 0.0093 + 0.0052

= 0.015 kW

MEASURE CODE: RS-HVC-CFAN-V05-260101

REVIEW DEADLINE: 1/1/2030

[671] Assumes the CF is the same as a Room AC. Consistent with coincidence factors found in: RLW Report: Final Report Coincidence Factor Study Residential Room Air Conditioners, June 23, 2008.

[672] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs. Average of values for standard and specialty bulbs.

5.3.16 Advanced Thermostats

DESCRIPTION

This measure characterizes the household energy savings from the installation of a new thermostat(s) for reduced heating and cooling consumption through a configurable schedule of temperature setpoints (like a programmable thermostat) *and* automatic variations to that schedule to better match HVAC system runtimes to meet occupant comfort needs. These schedules may be defaults, established through user interaction, and be changed manually at the device or remotely through a web or mobile app. Automatic variations to that schedule could be driven by local sensors and software algorithms, and/or through connectivity to an internet software service. Data triggers to automatic schedule changes might include, for example: occupancy/activity detection, arrival & departure of conditioned spaces, optimization based on historical or population-specific trends, weather data and forecasts.[673] This class of products and services are relatively new, diverse, and rapidly changing. Generally, the savings expected for this measure aren't yet established at the level of individual features, but rather at the system level and how it performs overall. Like programmable thermostats, it is not suitable to assume that heating and cooling savings follow a similar pattern of usage and savings opportunity, and so here too this measure treats these savings independently. Note that this is an active area of ongoing work to better map features to savings value, and establish standards of performance measurement based on field data so that a standard of efficiency can be developed.[674] Since energy savings are applicable at the household level, savings should only be claimed for one thermostat of any type (i.e., one programmable thermostat or one advanced thermostat), and installation of multiple thermostats per home does not accrue additional savings.

Note that though these devices and service could potentially be used as part of a demand response program, the costs, delivery, impacts, and other aspects of DR-specific program delivery are not included in this characterization at this time, though they could be added in the future.

This measure was developed to be applicable to the following program types: TOS, NC, RF, DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The criteria for this measure are established by replacement of a manual-only or programmable thermostat, with one that has the default enabled capability—or the capability to automatically—establish a schedule of temperature setpoints according to driving device inputs above and beyond basic time and temperature data of conventional programmable thermostats. As summarized in the description, this category of products and services is broad and rapidly advancing in regard to their capability, usability, and sophistication, but at a minimum must be capable of two-way communication[675] and exceed the typical performance of manual and conventional programmable thermostats through the automatic or default capabilities described above.

DEFINITION OF BASELINE EQUIPMENT

The baseline is either the actual type (manual or programmable) if it is known,[676] or an assumed mix of these two types based upon information available from evaluations or surveys that represent the population of program

[673] For example, the capabilities of products and added services that use ultrasound, infrared, or geofencing sensor systems, automatically develop individual models of home's thermal properties through user interaction, and optimize system operation based on equipment type and performance traits based on weather forecasts demonstrate the type of automatic schedule change functionality that apply to this measure characterization.

[674] The ENERGY STAR program released version 1.0 of its Connected Thermostats Specification in 2017. Details and active discussion can be found on ENERGY STAR website; 'Connected Thermostats Specifications v1.0'.

[675] This measure recognizes that field data may be available, through this 2-way communication capability, to better inform characterization of efficiency criteria and savings calculations. It is recommended that program implementations incorporate this data into their planning and operation activities to improve understanding of the measure to manage risks and enhance savings results.

[676] If the actual thermostat is programmable and it is found to be used in override mode or otherwise effectively being operated like a manual thermostat, then the baseline may be considered to be a manual thermostat.

participants. This mix may vary by program, but as a default, 51% programmed programmable and 49% manual or non-programmed programmable thermostats may be assumed.[677]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for advanced thermostats is assumed to be 11 years.[678]

DEEMED MEASURE COST

For DI and other programs for which installation services are provided, the actual material, labor, and other costs should be used. For retail, Bring Your Own Thermostat (BYOT) programs,[679] or other program types, actual costs are still preferable,[680] but if unknown, then the average incremental cost for the new installation measure is assumed to be $79.[681]

LOADSHAPE

ΔkWh → Loadshape R10 - Residential Electric Heating and Cooling
$\Delta kWh_{heating}$ → Loadshape R09 - Residential Electric Space Heat
$\Delta kWh_{cooling}$ → Loadshape R08 - Residential Cooling

COINCIDENCE FACTOR

In the absence of conclusive results from empirical studies on peak savings, the TAC agreed to a temporary assumption of 50% of the cooling coincidence factor, acknowledging that while the savings from the advanced Thermostat will track with the cooling load, the impact during peak periods may be lower. This is an assumption that could use future evaluation to improve these estimates.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)
= 34%[682]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)
= 23.3%[683]

[677] Based on Opinion Dynamics Corporation, "ComEd Residential Saturation/End Use, Market Penetration & Behavioral Study", Appendix 3: Detailed Mail Survey Results, p34, April 2013.
[678] Based on 2017 Residential Smart Thermostat Workpaper, prepared by SCE and Nest for SCE (Work Paper SCE17HC054, Revision #0). Estimate ability of smart systems to continue providing savings after disconnection and conduct statistical survival analysis which yields 9.2-13.8 year range.
[679] In contrast to program designs that utilize program affiliated contractors or other trade ally partners that support customer participation through thermostat distribution, installation and other services , BYOT programs enroll customers *after* the time of purchase through online rebate and program integration sign-ups.
[680] Including any one-time software integration or annual software maintenance, and or individual device energy feature fees.
[681] Market prices vary considerably in this category, generally increasing with thermostat capability and sophistication. The core suite of functions required by this measure's eligibility criteria are available on units readily available in the market roughly in the range of $100 and $150, excluding the availability of time or market-limited wholesale or volume pricing. Analysis of the 2021 Pricing data from AIC's Retail Products Program finds an average retail cost of $129 for Advanced Thermostats. The assumed cost for the baseline equipment (blend of manual and programmable thermostats) is $50 which leads to an incremental cost of $79 for the measure. See AIC_RetailProducts_2021Costdata_AdvThermostats_051322.xlsx for analysis of the AIC program data. Note that any add-on energy service costs, which may include one-time setup and/or annual per device costs are not included in this assumption.
[682] Assumes 50% of the cooling coincidence factor (based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory).
[683] Assumes 50% of the cooling coincidence factor (based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.)

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

ΔkWh[684] = $\Delta kWh_heatingElectric + \Delta kWh_heatingFurnace + \Delta kWh_{cooling}$

$\Delta kWh_heatingElectric$ = %ElectricHeat * Elec_Heating_Consumption * Heating_Reduction * HF * Eff_ISR_Heat

$\Delta kWh_heatingFurnace$ = If *furnace* (fossil fueled or electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = $\Delta Therms * F_e * 29.3$

If electric furnace: = $\Delta kWh_heatingElectric * F_e$

ΔkWh_{cool} = %AC * ((FLH * Capacity * 1/ηCool)/1000) * Cooling_Reduction * Eff_ISR_Cool

Where:

%ElectricHeat = Percentage of heating savings assumed to be electric

Heating fuel	%ElectricHeat
Electric	100%
Natural Gas	0%
Unknown	3%[685]

Elec_Heating_Consumption

= Estimate of annual household heating consumption for electrically heated homes.[686] If location and heating type is unknown, assume 15,683 kWh.[687]

Climate Zone (City based upon)	Electric Resistance (Baseboard or Electric Furnace) Elec_Heating_ Consumption (kWh)	Electric Heat Pump Elec_Heating_ Consumption (kWh)
1 (Rockford)	21,748	12,793
2 (Chicago)	20,777	12,222
3 (Springfield)	17,794	10,467
4 (Belleville)	13,726	8,074
5 (Marion)	13,970	8,218
Average	19,749	11,617

[684] Electrical savings are a function of both heating and cooling energy usage reductions. For heating this is a function of the percent of electric heat (heat pumps) and fan savings in the case of a natural gas furnace.

[685] Value used is based on known PY8 percent of electric heat provided by Navigant as part of the ongoing evaluation work source: "Slide 21: May 22, 2018, Second Addendum IL TRM Advanced Thermostat Cooling Savings Evaluation"

[686] Values in table are based on converting an average household heating load (834 therms) for Chicago based on 'Table E-1, Energy Efficiency/Demand Response Nicor Gas Plan Year 1: Research Report: Furnace Metering Study, Draft, Navigant, August 1 2013 to an electric heat load (divide by 0.03412) to electric resistance and ASHP heat load (resistance load reduced by 15% to account for distribution losses that occur in furnace heating but not in electric resistance while ASHP heat is assumed to suffer from similar distribution losses) and then to electric consumption assuming efficiencies of 100% for resistance and 200% for HP (see 'Household Heating Load Summary Calculations_08222018.xls'). Finally these values were adjusted to a statewide average using relative HDD assumptions to adjust for the evaluation results focus on northern region. Values for individual cities are then calculated by comparing average HDD to the individual city's HDD.

[687] Assumption that 1/2 of electrically heated homes have electric resistance and 1/2 have Heat Pump, based on 2010 Residential Energy Consumption Survey for Illinois.

Heating_Reduction = Assumed percentage reduction in total household heating energy consumption due to advanced thermostat including accounting for Thermostat Optimization services[688]

Existing Thermostat Type	Heating_Reduction[689]				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Manual	10.20%				
Programmable	7.10%				
Unknown (Blended)[690]	8.0%	8.5%	8.7%	8.9%	8.4%

HF = Household factor, to adjust heating consumption for non-single-family households.

Household Type	HF
Single-Family	100%
Mobile home	83%[691]
Multifamily	65%[692]
Actual	Custom[693]
Unknown	96.5%[694]

Use Multifamily if: Building meets utility's definition for multifamily and system serves single unit. For residential sized systems serving 2 or more units, assume single family hours. For central systems use Volume 2 Commercial and Industrial Measures.

Eff_ISR_Heat = Effective In-Service Rate for heating, the percentage of thermostats installed and configured effectively for 2-way communication. Note that retrospective adjustments should be made during evaluation verification activities through the use of a realization rate if the program design does not ensure that each advanced thermostat is actually installed and/or if the evaluation determines that the advanced thermostat is not actually installed in the Program Administrator's service territory.

[688] This estimate is based on a consumption data analysis with matching to non-participants and is therefore net with respect to participant spillover and between net and gross with respect to free ridership. Like all consumption data analyses, it is gross with respect to non-participant spillover. For more detail, see Table 5-3 in Volume 4 of the IL-TRM. Consistent with Section 7.2 of the Illinois EE Policy Manual, applicable net-to-gross adjustments to these factors will be determined as part of the annual SAG net-to-gross process.

[689] These values represent adjusted baseline savings values (8.8% for manual, and 5.6% for programmable thermostats) as presented in Navigant's PowerPoint on Impact Analysis from Preliminary Gas savings findings (slide 28 of 'IL SAG Smart Thermostat Preliminary Gas Impact Findings 2015-12-08 to IL SAG.ppt'), and incorporate any inherent in service rate impact. These values are adjusted upwards in v9 to account for inclusion of Thermostat Optimization savings in an estimated 40% of future participants (based on reported share of Nest and ecobee participants and 2020 rates of Thermostat Optimization and including an assumed 90% ISR consistent with the Guidehouse cooling savings study). The basis for the Thermostat Optimization savings is Navigant "ComEd CY2018 Seasonal Savings Heating Season Impact Evaluation Report", March 2019.

[690] The weighting of manual to programmable thermostats by market sector is based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential baseline Study Results", Oct 31 2024. See "Res Baseline Study Workbook.xls" for more detail.

[691] Since mobile homes are similar to Multifamily homes with respect to conditioned floor area but to single-family homes with respect to exposure (i.e., all four wall orientations are adjacent to the outside), this factor is estimated as an average of the single family and multifamily household factors.

[692] Multifamily household heating consumption relative to single-family households is affected by overall household square footage and exposure to the exterior. This 65% reduction factor is applied to MF homes, based on professional judgment that average household size, and heat loads of MF households are smaller than single-family homes

[693] Program-specific household factors may be utilized on the basis of sufficiently validated program evaluations.

[694] When Household type is unknown, a value of 96.5% may be used as a weighted average of 90% SF and 10% MF (96.5% = 100%*90% + 65%*10%) based on a Navigant evaluation of PY8 participants in ComEd's advanced thermostat program.

Program Delivery	Eff_ISR_Heat
Direct Install	100%
Self-install with Thermostat provided free of charge	54%[695]
Other programs where not evaluated	100%[696]

ΔTherms = Therm savings if Natural Gas heating system

= See calculation in Fossil Fuel section below

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[697]

29.3 = kWh per therm

%AC = Fraction of customers with thermostat-controlled air-conditioning

Thermostat control of air conditioning?	%AC[698]
Yes	100%
No	0%
Unknown (AC-targeted program)	99%
Unknown (general program)	82.5%

FLH = Estimate of annual household full load cooling hours for air conditioning equipment based on location and home type. If climate zone is unknown, assume the weighted average for the relevant home type. If both climate zone and home type are unknown, assume 723 hours.[699]

Climate zone (city based upon)	FLH (single family) [700]	FLH (general multifamily) [701]	FLH_cooling (weatherized multifamily) [702]
1 (Rockford)	547	499	320

[695] The 2022 and 2023 Opinion Dynamics evaluations showed that many single family participants who signed up to receive a self-install advanced thermostat did not install it. The value represents an average of the two evaluation years.

[696] As a function of the method for determining savings impact of these devices, in-service rate effects are already incorporated into the savings value for heating_reduction above.

[697] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBTU/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STARversion 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[698] 99% of ComEd PY8 program participants (AC targeted programs) have Central AC per communication with Navigant's ongoing 2017/2018 cooling savings evaluation. Non-targeted programs are still expected to have participation with %AC above general population rates. 82.5% is an average of the 99% program participation rate, and the 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey ;

[699] When both climate zone and home type are unknown, a value of 723 hours may be used as a weighted average of 90% SF and 10% MF (723 = 731*90% + 655*10%) based on a Navigant evaluation of PY8 participants in ComEd's advanced thermostat program.

[700] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[701] Ibid.

[702] *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

Climate zone (city based upon)	FLH (single family) [700]	FLH (general multifamily) [701]	FLH_cooling (weatherized multifamily) [702]
2 (Chicago)	709	629	403
3 (Springfield)	779	707	453
4 (Belleville)	1082	982	630
5 (Marion/Murphysboro)	956	868	557
Weighted Average[703]			
ComEd	676	603	386
Ameren	875	791	507
Statewide	731	655	420

Use Multifamily if: Building meets utility's definition for multifamily and system serves single unit. For residential sized systems serving 2 or more units, assume single family hours. For central systems use Volume 2 Commercial and Industrial Measures.

Capacity = Size of AC unit. (Note: One refrigeration ton is equal to 12,000 Btu/hr)

= Use actual when program delivery allows size of AC unit to be known. If unknown assume 33,600 Btu/hr for single family homes, 28,000 Btu/hr for multifamily or 24,000 Btu/hr for mobile homes.[704] If building type is unknown, assume 33,040 Btu/hr.[705]

ηCool = the cooling equipment's Seasonal Energy Efficiency Ratio rating (kBtu/kWh) * Distribution Efficiency

= Use actual SEER2 rating where it is possible to measure or reasonably estimate (assuming 85% distribution efficiency if only equipment efficiency is available). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[706]. If unknown, use the following assumption (do not derate further by age):

Cooling System	SEER2[707]	ηCool (SEER2 * 0.85)
Air Source Heat Pump	11.4	9.7
Central AC		

1/1000 = kBtu per Btu

Cooling_Reduction = Assumed average percentage reduction in total household cooling energy consumption due to installation of advanced thermostat including accounting

[703] Weighted based on number of occupied residential housing units in each zone. Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[704] Single family cooling capacity based on Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), October 19, 2010, ComEd, Navigant Consulting. Multifamily capacity based on weighted average of PY9 Ameren and ComEd MF cooling capacities. Mobile home capacity based on ENERGY STAR's Manufactured Home Cooling Equipment Sizing Guidelines which vary by climate zone and home size. The average size of a mobile home in the East North Central region (1,120 square feet) from the 2015 RECS data is used to calculated appropriate size.

[705] Unknown is based on statewide weighted average of 90% single family and 10% multifamily, based on a Navigant evaluation of PY8 participants in ComEd's advanced thermostat program.

[706] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[707] Estimate based upon Navigant, 2018 "EIA – Technology Forecast Updates – Residential and Commercial Building Technologies – Reference Case", converted to SEER2.

for Thermostat Optimization:[708]

= 8.4% [709]

Eff_ISR_Cool = Effective In-Service Rate for cooling, the percentage of thermostats installed and configured effectively for 2-way communication. Note that retrospective adjustments should be made during evaluation verification activities through the use of a realization rate if the program design does not ensure that each advanced thermostat is actually installed and/or if the evaluation determines that the advanced thermostat is not actually installed in the Program Administrator's service territory.

Program Delivery	Eff_ISR_Cool
Direct Install	100%
Self-install with Thermostat provided free of charge	54%[710]
Other programs where not evaluated	90%[711]

For example, an advanced thermostat replacing a programmable thermostat direct-installed in an electric heat pump heated, single-family home in Springfield with advanced thermostat-controlled air conditioning of a system of unknown size and seasonal efficiency rating:

$\Delta kWH = \Delta kWh_{heating} + \Delta kWh_{cooling}$

= 1 * 10,464 * 7.1% * 100% * 100% + (0 * 0.0314 * 29.3) + 100% * ((779 * 33,600 * (1/9.7))/1000) * 8.4% * 100%

= 743kWh + 227 kWh

= 970 kWh

[708] Note that "Cooling_Reduction" percentage is the savings expected from reduced cooling use, and is not the same as % cooling savings that are based on total kWh saved (including fan and heating kWh savings) as a percent of total kWh used for cooling.

[709] The Cooling_Reduction assumption is based on a TAC agreement to weight the consumption data analysis result (econometric) and the adjusted ENERGY STAR method for estimating runtime savings for advanced thermostats with stakeholder assumptions about baseline behavior (ENERGY STAR), provided by Guidehouse in 2020. The econometric result (7.8%) is weighted at 90%, and the ENERGY STAR result (10-14% range taken as reasonable by stakeholders, however 14% is used to account for increased Thermostat Optimization) weighted at 10%.

This econometric value is based upon the non-weather normalized savings percentage, adjusted for selection bias, %AC and ISR, with additional adjustment to account for the anticipated growth in Thermostat Optimization savings, from 12% of participants in the study to 45% of future participants (based on reported share of Nest and ecobee participants and 2020 rates of Thermostat Optimization). The basis for the Thermostat Optimization savings is Navigant's "ComEd CY2018 Seasonal Savings Cooling Season Impact Evaluation Report", March 2019. The estimate of cooling reduction factor includes an adjustment for apparent selection bias, per stakeholder request as part of a 2020 study by Guidehouse involving a consumption analysis of ComEd advanced thermostat rebate recipients. Guidehouse acknowledges that this adjustment is a coarse method of addressing potential bias, but believes that this adjustment may not be accurate or applicable for future studies of this type.

The adjusted ENERGY STAR analysis is gross with respect to all components of net-to-gross (free ridership, and participant and non-participant spillover). The econometric analysis uses matching to future participants and is therefore gross with respect to free ridership. Like all consumption data analyses, it is net with respect to participant spillover and gross with respect to non-participant spillover. For more detail, see Table 5-3 in Volume 4 of the IL-TRM. Consistent with Section 7.2 of the Illinois EE Policy Manual, applicable net-to-gross adjustments to these factors will be determined as part of the annual SAG net-to-gross process.

[710] The 2022 and 2023 Opinion Dynamics evaluations showed that many single family participants who signed up to receive a self-install advanced thermostat did not install it. The value represents an average of the two evaluation years.

[711] The 2020 Guidehouse evaluation indicated that 6.75% of participants installed the advanced thermostat out of state. An additional reduction is applied to account for purchases that are never installed. Based on the available data this is estimated as an additional 3.75%.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = %AC * (Cooling_DemandReduction * Btu/hr * (1/EER2)/1000) * EFF_ISR_Cool * CF

Where:

Cooling_DemandReduction = Assumed average percentage reduction in total household cooling demand due to installation of advanced thermostat including accounting for Thermostat Optimization services

= 16.4%[712]

EER2 = Energy Efficiency Ratio of existing cooling system (kBtu/hr / kW)

= Use actual EER2 rating where it is possible to measure or reasonably estimate. If EER2 unknown but SEER2 available convert using the equation:

$EER2 = (-0.02 * SEER2_exist^2) + (1.12 * SEER2_exist)$ [713]

If SEER2 or EER2 rating unavailable, use:

Cooling System	EER2[714]
Air Source Heat Pump	10.0
Central AC	

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)
= 34%[715]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)
= 23.3%[716]

For example, an advanced thermostat replacing a programmable thermostat directly installed in an electric resistance heated, single-family home in Springfield with advanced thermostat-controlled air conditioning of a system of unknown size and seasonal efficiency rating:

ΔkW_{SSP} = 100% * (16.4% * 33,600 * (1/10.0)/1000) * 100% * 34%
= 0.1874 kW

ΔkW_{PJM} = 100% * (16.4% * 33,600 * (1/10.0)/1000) * 100% * 23.3%
= 0.1284 kW

[712] The current Cooling_DemandReduction assumption is based on results presented on August 4th, 2020 from a Guidehouse econometric analysis and further refinements discussed throughout August.
The final value is based upon the non-weather normalized savings percentage, adjusted for selection bias, %AC and ISR, provided by the Guidehouse econometric results, and includes an additional adjustment to account for the anticipated growth in Thermostat Optimization savings, The estimate of cooling reduction factor includes an adjustment for apparent selection bias, per stakeholder request as part of a 2020 study by Guidehouse involving a consumption analysis of ComEd advanced thermostat rebate recipients. Guidehouse acknowledges that this adjustment is a coarse method of addressing potential bias, but believes that this adjustment may not be accurate or applicable for future studies of this type.
[713] From Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder.
[714] Based on converting SEER2 assumption to EER2.
[715] Assumes 50% of the cooling coincidence factor (based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.)
[716] Assumes 50% of the cooling coincidence factor (based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.)

FOSSIL FUEL SAVINGS

$$\Delta Therms = \%FossilHeat * Gas_Heating_Consumption * Heating_Reduction * HF * Eff_ISR_Heat$$

Where:

%FossilHeat = Percentage of heating savings assumed to be Natural Gas

Heating fuel	%FossilHeat
Electric	0%
Natural Gas	100%
Unknown	97%[717]

Gas_Heating_Consumption

= Estimate of annual household heating consumption for gas heated single-family homes. If location is unknown, assume the average below.[718]

Climate Zone (City based upon)	Gas_Heating_ Consumption (therms)
1 (Rockford)	1,052
2 (Chicago)	1,005
3 (Springfield)	861
4 (Belleville)	664
5 (Marion)	676
Average	955

Other variables as provided above.

For example, an advanced thermostat replacing a programmable thermostat directly-installed in a gas heated single-family home in Chicago:

ΔTherms = 1.0 * 1005 * 7.1% * 100% * 100%

= 71.4 therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

[717] Value used is based on known PY8 percent of electric heat provided by Navigant as part of the ongoing evaluation work source: "Slide 21: May 22, 2018, Second Addendum IL TRM Advanced Thermostat Cooling Savings Evaluation"

[718] Values are based on adjusting the average household heating consumption (849 therms) for Chicago based on 'Table 3-4, Program Sample Analysis, Nicor R29 Res Rebate Evaluation Report 092611_REV FINAL to Nicor', calculating inferred heating load by dividing by average efficiency of new in program units in the study (94.4%) and then applying standard assumption of existing unit efficiency of 83% (estimate based on 24% of furnaces purchased in Illinois were condensing in 2000 (based on data from GAMA, provided to Department of Energy), assuming typical efficiencies: (0.24*0.92) + (0.76*0.8) = 0.83). This Chicago value was then adjusted to a statewide average using relative HDD assumptions to adjust for the evaluation results focus on northern region. Values for individual cities are then calculated by comparing average HDD to the individual city's HDD.

MEASURE CODE: RS-HVC-ADTH-V11-260101

REVIEW DEADLINE: 1/1/2028

5.3.17 Gas High Efficiency Combination Boiler

DESCRIPTION

Space heating boilers are pressure vessels that transfer heat to water for use in space heating. Boilers either heat water using a heat exchanger that works like an instantaneous water heater or by adding/connecting a separate tank with an internal heat exchanger to the boiler. A combination boiler contains a separate heat exchanger that heats water for domestic hot water use. Qualifying combination boilers must be whole-house units used for both space heating and domestic water heating with one appliance and energy source. Only participants who have a natural gas account with a participating natural gas utility are eligible for this rebate.

Optionally, when applying an early replacement rate for two-in-one boiler upgrades, the following weighted average is provided for use in downstream programs when the actual baseline early replacement rates are unknown.[719]

Deemed Early Replacement Rates for Boilers

	Deemed Early Replacement Rate
Early Replacement Rate for Boiler participants	7%

This measure was developed to be applicable to the following program types: TOS or ER. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is a condensing combination boiler unit with boiler AFUE of 90% or greater. The combination boiler must have a sealed combustion unit and be capable of modulating the firing rate and must be accompanied by a programmed outdoor reset control.[720] Measures that do not qualify for this incentive include boilers with a storage tank and redundant or backup boilers.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a boiler with the federal minimum of 84% AFUE and a residential, natural gas-fueled storage water heater meeting minimum Federal efficiency standards as described below:

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[721]
Residential Gas Storage Water Heaters ≤75,000 Btu/h	≤55 gallon tanks	Very small	UEF = 0.3456 – (0.0020 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5982 – (0.0019 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6483 – (0.0017 * Rated Storage Volume in Gallons)
		High	UEF = 0.6920 – (0.0013 * Rated Storage Volume in Gallons)
	>55 gallon and ≤100 gallon tanks	Very small	UEF = 0.6470 – (0.0006 * Rated Storage Volume in Gallons)
		Low	UEF = 0.7689 – (0.0005 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.7897 – (0.0004 * Rated Storage Volume in Gallons)
		High	UEF = 0.8072 – (0.0003 * Rated Storage Volume in Gallons)

[719] Based upon research from "Home Energy Efficiency Rebate Program GPY2 Evaluation Report" which outlines early replacement rates for both primary and secondary central air cooling (CAC) and residential furnaces. This is used as a reasonable proxy for boiler installations since boiler specific data is not available. Report presented to Nicor Gas Company February 27, 2014.

[720] In a 2015 study, the Cadmus Group team conducted an analysis of optimal outdoor reset curves and discovered that "a boiler in Massachusetts with well-programmed outdoor reset controls could see an operating efficiency improvement of up to 3 to 4 percentage points from the average efficiency of 88.4% observed".

[721] DOE Standard 10 CFR 430, Residential-Duty and Commercial Federal Standard are from DOE Standard 10 CFR 431. Minimum Federal standard as of 4/16/2015, confirmed no changes as of 6/20/2021; https://www.ecfr.gov/cgi-bin/text-idx?SID=80dfa785ea350ebeee184bb0ae03e7f0&mc=true&node=se10.3.430_132&rgn=div8

Draw patterns are based on first hour rating (gallons) for storage tanks as shown below:[722]

Storage Water Heater Draw Pattern	
Draw Pattern	**First Hour Rating (gallons)**
Very Small	≥ 0 and < 18
Low	≥ 18 and < 51
Medium	≥ 51 and < 75
High	≥ 75

If using a deemed approach, for storage water heaters with a storage capacity equal to or less than 55 gallons, the Federal energy factor requirement is calculated as 0.6483 – (0.0017 * storage capacity in gallons) assuming a Medium draw and 50 gallon tank (resulting in 0.5633 EF).

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 21.5 years.[723]

DEEMED MEASURE COST

The incremental measure cost is assumed to be $1,663 for a 90-94% AFUE unit and $2,421 for a unit greater than or equal to 95% AFUE.[724]

FOSSIL FUEL SAVINGS

$$\Delta Therms = \Delta Therm_{Boiler} + \Delta Therm_{WH}$$

$$\Delta Therms_{Boiler} = (EFLH * CAP_{Input} * (AFUE_{Eff} / AFUE_{Base} -1)) / 100{,}000$$

$$\Delta Therms_{WH} = (1/UEF_{Base} - 1/UEF_{Eff}) * (GPD * Household * 365.25 * \gamma_{Water} * (T_{OUT} – T_{IN}) * 1.0) / 100{,}000$$

Where:

CAP_{Input} = Gas Furnace input capacity (Btuh)

= Actual

EFLH = Equivalent Full Load Hours for gas heating

Climate Zone (City based upon)	EFLH[725]
1 (Rockford)	1022
2 (Chicago)	976
3 (Springfield)	836
4 (Belleville)	645
5 (Marion)	656
Weighted Average[726]	
ComEd	978
Ameren	800
Statewide	928

$AFUE_{Base}$ = Baseline boiler annual fuel utilization efficiency rating

= 84%

$AFUE_{Eff}$ = Efficent boiler annual fuel utilization efficiency rating

= Actual. If unknown, use defaults dependent on tier as listed below:[727]

Measure Type	$AFUE_{Eff}$
AFUE ≥ 90%	92.5%
AFUE ≥ 95%	95%

[725] Full load hours for Chicago, are based on findings in 'Energy Efficiency / Demand Response Nicor Gas Plan Year 1 (6/1/2011-5/31/2012) Research Report: Furnace Metering Study (August 1, 2013), prepared by Navigant Consulting, Inc. Values for other cities are then calculated by comparing relative HDD at base 60F.

[726] Weighting for Ameren is based on gas accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[727] Default values per tier selected based upon the average AFUE value for the tier range except for the top tier where the minimum is used due to proximity to the maximum possible.

UEF_{Base} = Uniform Energy Factor rating of standard storage water heater according to federal standards provided in table in baseline section. For a deemed approach:

= For gas storage water heaters ≤55 gallons: 0.6483 – (0.0017 * storage capacity in gallons)

= For gas storage water heaters >55 gallons: 0.8072 − (0.0003 × storage capacity in gallons)

= If tank size is unknown, assume 0.563 for a gas storage water heater with a 50-gallon storage capacity

UEF_{Eff} =Uniform Energy Factor rating for efficient combination boiler. This is assumed consistent with a condensing instantaneous gas-fired water heater.

= 0.954 [728]

GPD = Gallons per day of hot water use per person

= 45.5 gallons hot water per day per household/2.59 people per household [729]

= 17.6

Household = Average number of people per household

Household Unit Type	Household[730]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[731]
Custom	Actual Occupancy or Number of Bedrooms[732]		

Use Multifamily if: Building meets utility's definition for multifamily

365.25 = Days per year, on average

γ_{Water} = Specific weight of water

= 8.33 pounds per gallon

T_{OUT} = Tank temperature

= 125°F

T_{IN} = Incoming water temperature from well or municipal system

= 50.7°F [733]

1.0 = Heat capacity of water (1 Btu/lb*°F)

[728] Average Uniform Energy Factor from CAC appliance database accessed 4/22/2022 for instantaneous gas-fired water heaters. The water heater portion of a gas high efficiency combination boiler is essentially a tankless water heater.

[729] Deoreo, B., and P. Mayer. Residential End Uses of Water Study Update. Forthcoming. ©2015 Water Research Foundation. Reprinted With Permission.

[730] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.

[731] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.

[732] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

[733] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

For example, a Rockford single-family IQ home installing an 80,000 Btuh condensing combination boiler unit with boiler AFUE of 95%:

$\Delta Therms_{Boiler}$ = (1,022 * 80,000 * (0.95/0.84 - 1))/100,000

$\Delta Therms_{WH}$ = (1/0.5863 – 1/0.954) * (17.6 * 2.76 * 365.25 * 8.33 * (125-50.7) *1.0)/100,000

ΔTherms = 107.1 + 72.2

= 179.3 Therms

5.3.18 Furnace Filter Alarm – Provisional Measure

Measure has been removed in v9.0 due to evaluation results showing filter alarms being ineffectual at indicating a dirty filter.

5.3.19 Thermostatic Radiator Valves – Provisional Measure

DESCRIPTION

Thermostatic Radiator Valves (TRVs) are installed on hydronic or steam radiators to provide temperature control within a room or space. The TRV is a self-regulating valve requiring no auxiliary power, allowing the user to set the temperature to their preferred set point. On hydronic and two-pipe steam systems, as the room temperature rises the valve head expands, blocking the flow of hot water or steam into the radiator. On a one-pipe steam system the TRVs are installed on the air vent and limit the amount of air escaping the radiator, which in turn limits the amount of steam filling the radiator.

The current measure is limited to retrofit application in Multifamily buildings. TRVs are particularly effective in large multifamily buildings where some rooms tend to be overheated resulting in tenants leaving windows open even in winter.

From limited evaluation results, savings appear to be dependent on being part of a whole system commissioning and balancing project.

This measure was developed to be applicable to the following program types: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the TRV is installed on an existing hydronic or steam heated radiator in a multifamily building.

DEFINITION OF BASELINE EQUIPMENT

The baseline is an existing hydronic or steam heated radiator without a TRV installed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life of a TRV is estimated as 15 years.[734]

DEEMED MEASURE COST

The actual cost per TRV should be used. If unknown assume a measure cost of $200 for steam systems and $250 for hot water per TRV.[735] If the heating system is required to be drained, the full cost should be used and split between all TRVs installed.

FOSSIL FUEL SAVINGS

$$\Delta Therms = Gas_Heating_Load/(\mu Boiler * \#Radiators) * \%TRVSavings$$

Where:

ΔTherms = Therm savings per TRV installed

Gas_Heating_Load = Estimated Gas heating Load per multi family unit.[736]

Climate Zone (City based upon)	Gas_Heating_ Load per Multi family unit (therms)
1 (Rockford)	567
2 (Chicago)	542
3 (Springfield)	464
4 (Belleville)	358
5 (Marion)	365
Average	515

µBoiler = AFUE Efficiency of the boiler system

= Actual. If unknown assume 75%

#Radiators = Number of radiators in the multifamily unit.

= Actual. If unknown estimated as five.

%TRVSavings = Estimate of heating consumption savings from installing a TRV[737]

= 15% when part of a system balancing project to address overheated spaces

= 5% if installed without system balancing

[736] This assumption is based on the Single Family Gas Heating Consumption for boiler values provided in 5.3.14 Boiler Reset Controls (based on Table 3-4, Program Sample Analysis, *Nicor R29 Res Rebate Evaluation Report 092611_REV FINAL to Nicor)* multiplied by a 65% adjustment factor, which is used to account for the expected lower multifamily heating consumption relative to single-family households due to overall household square footage and exposure to the exterior.

[737] Based on literature review of a limited number of studies available including:
Department of Energy, Dentz et al, "Thermostatic Radiator Valve Evaluation", January 2015.
NYSERDA "Thermostatic Radiator Valve Demonstration Project", 1995.
Lublin University of Technology Cholewa et al "Actual energy savings from the use of thermostatic radiator valves in residential buildings – Long term field evaluation", July 2017.

For example, a TRV is installed on three of five radiators in a multifamily unit with a central 75% AFUE hydronic boiler, as part of a system balancing project in Chicago.

ΔTherms per TRV = Gas_Heating_Load/(µBoiler * #Radiators) * %TRVSavings

= 542 / (0.75 * 5) * 0.15

= 21.7 Therms

Total of 19.6 * 3 = 65.1 Therms for the multi family unit

5.3.20 Residential Energy Recovery Ventilator (ERV)

DESCRIPTION

Unconditioned outdoor air is typically warmer or cooler than desired by the occupants and is often also more humid than desired. A Residential ERV system provides necessary outdoor air ventilation while preheating or precooling the outdoor air, and, in some Residential ERV systems, pre-dehumidifying the outdoor air as well. This saves energy required for heating, cooling, and dehumidifying the residence.

An ERV generally comprises two fans (Exhaust and Outdoor Intake) that pass the two streams of air through a heat exchanger, which may be a fixed plate heat exchanger or a rotary heat recovery wheel. Sensible heat from the warmer air stream is transferred to the cooler air stream, thereby reducing the amount of heating energy or cooling energy needed to condition the outdoor air to desired indoor air temperature and humidity levels. The heat exchanger surfaces, in some ERV models, may be coated with a hydroscopic material that absorbs/releases or transfers latent moisture from one air stream to the other. This increases the overall energy transfer efficiency during humid summer months by partially dehumidifying moist outdoor air using the relatively drier indoor exhaust air. In the winter, this same effect serves to humidify the outdoor air, making the space more comfortable, but not saving significant energy.

The current measure serves all residential single family and Group R2, R3 and R4 dwellings of 3 stories or less, both existing and new, where ERV is not required to comply with energy code.

This measure was developed to be applicable to electric cooling systems and electric or natural gas heating systems in the following program types: RF, NC, TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The Residential ERV, proposed for installation, must be listed in the Home Ventilation Institute's HVI-Certified Ratings Listing by its Brand and Model Number, and the HVI-Certified Ratings Listing must include the Model's Maximum CFM, ASRE (Adjusted Sensible Recovery Efficiency) and ATRE (Adjusted Total Recovery Efficiency) ratings values.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a residential HVAC system with no energy recovery ventilator installed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life of an ERV is estimated as 15 Years.[738]

DEEMED MEASURE COST

The actual cost of the ERV should be used. If unknown assume an incremental measure cost of $25.00 per Maximum CFM HVI-Certified Rating of proposed Brand and Model Number.[739]

LOADSHAPE

R11 - Residential Ventilation

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate

[738] State of Minnesota Technical Reference Manual, version 3, pp. 350+.
https://mn.gov/commerce/industries/energy/utilities/cip/technical-reference-manual/

[739] This installed cost amount is estimated by Leidos based on 2Q2021 list prices from SupplyHouse.com for a variety of ERVs of nominally 95-117 CFM capacity plus an estimated $2,000 per ERV for electrical and mechanical installation services, divided by the Maximum listed CFM specified in the Home Ventilating Institute's Certified Products Directory for the specific ERVs offered by SupplyHouse.com. Unit installed prices ranged from $24.27 to $28.93 per CFM based on the above.

peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period and is presented so that savings can be bid into PJM's Forward Capacity Market.

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for ERV (during utility peak hour)

= 95%[740]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for ERV (average during PJM peak period)

= 95%[741]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

ERV Electric Heating Savings

If residence uses Electric heating,

ΔkWh_heating = 1.08 * HVI_Max_CFM * HDD60 * 24 * HVI_Rated_ASRE / ηHeat / 3412 * Daily_Hrs_Ventilation / 24 * %ElectricHeat

Where:

1.08 = Specific heat of air x density of inlet air @ 70F x 60 min/hr in BTU/hr-F-CFM

HVI_Max_CFM = HVI-Certified Maximum CFM of the Brand/Model of ERV proposed to be used[742]

If ERV Brand and Model are unknown, use the appropriate values in following Table of ERV Default Values[743]:

ERV Default Values:

	ERV Default Heating and Cooling CFM	ERV Default ASRE	ERV Default ATRE	ERV Default Watts
Single-family	114	70%	56%	94
Multi-family	64	65%	53%	49
Unknown Residence[744]	99	68%	55%	80
Custom	*Actual*	*Actual*	*Actual*	*Actual*

HDD60 = Heating Degree Days, base 60F, for the Climate Zone of Customer's site, from the following Table [745]

Table 1: Climate Variables

[740] Based on 24 hr /day, 7 day/w operation.

[741] Ibid.

[742] Please see file 'HVIProd_ER.xlsx' for all related values. This is a lookup based on Customer inputs of ERV Brand and Model Number, which must match one of the HVI-Certified listings.

[743] Table of ERV Default Values is based on all available ERV Certified Data from file 'HVIProd_ER.xlsx' published by Home Ventilating Institute (https://www.hvi.org/hvi-certified-products-directory/section-iii-hrv-erv-directory-listing/). This table lists certified values of 387 models of ERVs. The default values above assume that Single-family residences will install ERVs with Heating CFM > 75 and Multi-family residences will install ERVs with Heating CFM <= 75 cfm. The respective default values represent arithmetic averages of the respective HVI ERV values separated into these two ERV CFM ranges.

[744] Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions, and States, 2009. 69% Multi-Family and 31% Single Family.

[745] National Climatic Data Center, Cooling Degree Days are based on a base temp of 65°F and Heating Degree Days are based on a base temp of 60F. There is a county mapping table Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

Climate Zone (City based upon)	Climate Heating Factor (CHF)	Heating based on Sensible: HDD60	Cooling based on Sensible: CDD65	Heating Design Day DBT	Cooling Design Day DBT	Cooling Design Day OA Enthalpy	Heating Design Day OA Enthalpy	Cooling Design Day RA Enthalpy	Heating Design Day RA Enthalpy	ΔEnthalpy [746] (Btu-hr/lb)	Daily fan use[747]
1 (Rockford)	58%	5,230	877	0.3	88.0	41.0	0.07	28.36	25.34	6,375	17.8

5 (Marion)	46%	3,390	1,450	12.1	92.7	44.5	2.90	28.36	25.34	11,885	18.4

24 = Number of Hours in a Day [748]

HVI_Rated_ASRE = HVI-Certified Adjusted Sensible Recovery Efficiency of the Brand/Model of ERV proposed to be used[749]

= If ERV Brand and Model are unknown, use default values in previous table of ERV Default Values.

ηHeat = Efficiency of heating system

= Actual (where new or where it is possible to measure or reasonably estimate, assuming heat pump 85% distribution efficiency if only equipment efficiency is available). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[750] or if not available refer to default table below[751]. If unknown value is used, it should not be derated by age.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate)= (HSPF2/3.412)*0.85
Heat Pump (if age unknown assume 2006-2014)	Before 2006	5.8	1.44
	2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1
Unknown (for use in program evaluation only)[752]	N/A	N/A	1.28

[746] Base: 28.4 BTU/lb Return Air

[747] Based on defrost oversizing factor.

[748] Used to convert Annual HDD (F-Days) to total deltaT-hours (F-Hr) per year. Also used to convert daily ERV run hours to % runtime.

[749] Please see file 'HVIProd_ER.xlsx' for all related values. This is a lookup based on Customer inputs of ERV Brand and Model Number, which must match one of the HVI-Certified listings.

[750] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[751] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps.

[752] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North

3412 = Converts Btu to kWh

Daily_Hrs_Ventilation = Average annual daily ERV run time during which heat/cooling is being recovered, based on the assumption that ERV is selected to provide adequate ventilation rate when operated continuously on the coldest day of the year, when the defrost cycle interrupts heat recovery for a period of time depending on outdoor air temperature. ERV is assumed to be oversized so that on this coldest day, the ERV will provide the total ventilation air quantity during the minutes that is is not in defrost. As an example, if a coldest day results in 20% defrost time, the ERV is assumed to be selected at 1/0.8 or 125% oversizing. On the coldest day, the fan would operate 100% of the time. When not in defrost, it is assumed the homeowner would reduced fan operation to 80% runtime to avoid overventilating the residence. This assumed behavior results in an average annual runtime per day ranging from 17.8 to 18.9 hours/day.

The following defrost schedule is typical of ERV manufacturers and was used to calcuate average daily run hours:

OA DBT	Defrost	On	Total	% Runtime
27 F	3.0 Min.	25.0 Min.	28.0 Min.	89.3%
-4 F	4.5 Min.	17.0 Min.	21.5 Min.	79.1%
-31 F	7.0 Min.	15.0 Min.	22.0 Min.	68.2%

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= 0 % for Natural Gas

= If unknown[753], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[754]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[753] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[754] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

For example, assuming HVI Max CFM = 117 cfm; HDD60 = 5,552 (Rockford, IL); Electric Resistance Heat (COP=1.0); HVI Rated ASRE = 75%; Heating COP = 1.0; Daily_Hrs_Ventilation = 17.8; %ElectricHeat = 100%

ΔkWh_heating = ((1.08 * 117 * 5,552 * 24) * 75% / 1.0 / 3,412) * 17.8 / 24 * 100%

= 2,742 kWh of heating energy saved

ERV Electric Cooling Savings

If residence uses Electric cooling, the cooling savings is calculated by the following equation:

ΔkWh_cooling = 4.5 * HVI_Max_CFM * ΔEnthalpy * HVI_Rated_ATRE / 1000 / ηCool * Daily_Hrs_Ventilation / 24 * %Cool

Where:

4.5 = Density of inlet air at 70F x 60 min/hr in lb-min/ft3 -hr

HVI_Max_CFM = HVI-Certified Maximum CFM of the Brand/Model of ERV proposed to be used[755]

= If ERV Brand and Model are unknown, use default values in previous "Table of ERV Default Values".

ΔEnthalpy = Difference between Outdoor Air and Return Air Enthalpies (Btu/lb air) for each weather bin of the Climate Zone of Customer's site[756] times the number of hours of occurrence per year of each weather bin

= Values contained in Table 1, above, for 5 representative climate zones

= $\sum$ [($H_OA_Cool_{bin}$ - $H_RA_Cool_{bin}$) * $Annual\ Hours_{bin}$] summed over all temperature bins where $H_OA_Cool_{bin} > H_RA_Cool_{bin}$.

Where:

H_OA_Cool = Weather Bin Outdoor Air Enthalpy

H_RA_Cool = Cooling Mode Return Air Enthalpy = 28.36 Btu/lb, a deemed value.

1000 = Conversion of btu to kbtu.

ηCool = Efficiency (SEER2) of Air Conditioning equipment (kBtu/kWh) * Distribution Efficiency

= Actual (where new or where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for central cooling with ducts if only equipment efficiency is available). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[757] or if unknown assume the following.[758]

[755] Please see HVI Table at the end of this document. This is a lookup based on Customer inputs of ERV Brand and Model Number, which must match one of the HVI-Certified listings".

[756] This is based the Climate Zone based on the Customer's Site Address, informed by the Minnesota Technical Reference Manual v.3, page 350, commercial ERV measure assumptions modified for Illinois climate conditions using ASHRAE Design Data Tables. The table recreates enthalpy assumptions originating in the Minnesota TRM v3 for commercial ERV measure, page 350, tables 1 and 2, modified for Illinois climate conditions

[757] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[758] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

If unknown value is used, it should not be derated by age.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3
Room AC[759]		
Non-IQ	10.9	10.9
IQ	9.7	9.7
Unknown (for use in program evaluation only)[760]		
Single Family Non-IQ		10.6
Single Family IQ		10.3
Multi Family Non-IQ		10.3
Multi Family IQ		9.9
Unknown		10.3

HVI_Rated_ATRE = HVI-Certified Adjusted Total Heat Recovery Efficiency of the Brand/Model of ERV proposed to be used[761].

Daily_Hrs_Ventilation = As previously defined

24 = Hours in a day

%Cool = Percent of homes that have cooling

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[762]	98.9%	96.5%	99.8%	98.7%	98.6%

For example, assuming HVI Max CFM = 117 cfm; ΔEnthalpy = 6,375 BTU-hr/lb (Rockford, IL); Air Conditioner, vintage older than 2006 (ηCool = 9.5); HVI Rated ATRE = 48%; Daily_Hrs_Ventilation = 17.8; %Cool = 100%

ΔkWh_cooling = 4.5 * 117 * 6,375 / 1,000 / 9.5 * 48% * 17.8 / 24 * 100%

= 126 kWh

ERV Fan Energy Savings

For all heating or heating/cooling ERV applications, the ERV fan savings represents the change in energy usage of the ERV fan annual energy use versus the base case standard (non-ERV) exhaust fan energy use.

[759] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[760] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[761] Please see file 'HVIProd_ER.xlsx' for all related values. This is a lookup based on Customer inputs of ERV Brand and Model Number, which must match one of the HVI-Certified listings.

[762] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

The base case non-ERV exhaust fan energy use is deemed to be equal to the average ERV daily exhaust volume of air exhausted, times the deemed fan efficiency of a continuously-operated bathroom exhaust fan, as defined in Section 5.3.9 of IL-TRM_Effective_010122_v10.0_Vol_3_Res_08062021_DRAFT.docx: 1.7 CFM/Watt. The daily average total exhaust volume of the existing bathroom exhaust fan(s) is deemed to be equal to the proposed ERV daily average total exhaust volume, after taking into account the defrost cycle periods wherein ERV fan energy is consumed but no ventilation occurs.

Therefore:

Exist_Exh_Fan_Use = HVI_Rated_CFM * Daily_Hrs_Ventilation / 24 / 1.7 CFM/Watt / 1000 * Daily_Hrs_Fan_Use * 365.25

Where:

HVI_Rated_CFM = HVI-Certified Heating CFM at Maximum Air Flow of the Brand/Model of ERV proposed to be used[763]

= If ERV Brand and Model are unknown, use default values in previous "Table of ERV Default Values".

Daily_Hrs_Ventilation = As previously defined.

1.7 CFM/Watt = Deemed base case bathroom exhaust fan efficiency

24 = Hours in a Day

Daily_Hrs_Fan_Use = Deemed 24 hr/day because of continuous ERV fan use whether ERV is in defrost cycle or in ventilation cycle

365.25 = Days in a Year

1000 = Conversion of watts to kW

8766 = Annual Hours of Bathroom Fan Use

ERV_Fan_Use = HVI_Rated_W / 1000 * Daily_Hrs_Fan_Use * 365

Where:

HVI_Rated_W = HVI-Certified Wattage at Maximum Air Flow of the Brand/Model of ERV proposed to be used[764]

= If ERV Brand and Model are unknown, use default Watts/CFM in previous "Table of ERV Default Values" x ERV CFM (also from "Table of ERV Default Values").

1000 = Conversion of watts to kW

Daily_Hrs_Fan_Use = Deemed to be 24 hr/day because of continuous ERV fan use whether ERV is in defrost cycle or in ventilation cycle.

Savings (positive or negative) therefore are calculated by the following equation:

Exist_Exh_Fan_Use - ERV_Fan_Use

Where both terms in the equation are as previously defined.

[763] Please see file 'HVIProd_ER.xlsx' for all related values. This is a lookup based on Customer inputs of ERV Brand and Model Number, which must match one of the HVI-Certified listings.

[764] Please see file 'HVIProd_ER.xlsx' for all related values. This is a lookup based on Customer inputs of ERV Brand and Model Number, which must match one of the HVI-Certified listings".

For Example, assuming HVI_Rated_CFM = 117 CFM; HVI Rated Watts = 106 W; Daily_Hrs_Ventilation = 17.8; Daily_Hrs_Fan_Use = 24; Base Case Bathroom Exhaust Fan Efficiency = 1.7 CFM/Watt.

Exist_Exh_Fan_Use = 117 * 17.8 / 24 / 1.7 / 1000 * 24 * 365.25 = 447 kWh/Year

ERV_Fan_Use = 106 / 1,000* 24 * 365.25 = 929 kWh

ERV Fan Energy Savings = 447 kWh - 929 kWh = - (482) kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$\Delta kW = \Delta kWh_{Annual} / HOU * CF * Daily_Hrs_Ventilation / 24$

Where:

ΔkWh_{Annual} = ΔkWh_heating + ΔkWh_cooling

HOU = Annual Hours of Use of ERV, including defrost hours where fan recirculates indoor air through outdoor air heat exchanger.

= Actual. Use 8,766 hours/year if actual is not available.[765]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for ERV (during utility peak hour)

= 95%[766]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for ERV (average during PJM peak period)

= 95%[767]

Daily_Hrs_Ventilation = As defined previously.

24 = Hours in a day

For example, assuming Annual kWh Saved = 1,989 kWh/year; HOU = 8,766 Hr/Yr; CF = 0.95; Daily_hr_use = 17.8

ΔkW = 1,989 / 8,766 * 0.95 * 17.8 / 24

= 0.16 kW

FOSSIL FUEL SAVINGS

$\Delta Therms_{Annual}$ = 1.08 * HVI_Max_CFM * HDD60 * 24 * HVI_Rated_ASRE / ηHeat / 100,000 * Daily_Hrs_Ventilation / 24 * %FossilHeat

Where:

1.08 = Conversion of CFM air * delta T to BTU/hr

HVI_Max_CFM = HVI-Certified Maximum CFM of the Brand/Model of ERV proposed to be used[768]

[765] Deemed continual operation of ERV throughout year.
[766] Based on 24 hr /day, 7 day/w operation.
[767] Ibid.
[768] Please see file 'HVIProd_ER.xlsx' for all related values. This is a lookup based on Customer inputs of ERV Brand and Model Number, which must match one of the HVI-Certified listings.

HDD60 = Heating Degree Days base 60F, for the Climate Zone of Customer's site

= Value obtained from Table 1, above.

24 = Converts Days to Hours[769]

HVI_Rated_ASRE = HVI-Certified Adjusted Sensible Recovery Efficiency of the Brand/Model of ERV proposed to be used[770]

= If ERV Brand and Model are unknown, use default values in previous table of ERV Default Values.

ηHeat = Efficiency of heating system

= Equipment efficiency * distribution efficiency

= Actual (where new or where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency if only equipment efficiency is available).[771] If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[772] or if Equipment Efficiency is not available, use Section 5.3 to select the appropriate equipment efficiency for the project. If unknown value is used, it should not be derated by age.

100,000 = Converts Btu/hr to Therms

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for fossil fuel

= 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= If unknown[773], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[774]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

[769] Used to convert Annual HDD (F-Days) to total deltaT-hours (F-Hr) per year.

[770] Please see file 'HVIProd_ER.xlsx' for all related values. This is a lookup based on Customer inputs of ERV Brand and Model Number, which must match one of the HVI-Certified listings.

[771] Ideally, the System Efficiency should be obtained either by recording the AFUE of the unit, or performing a steady state efficiency test. The Distribution Efficiency can be estimated via a visual inspection and by referring to a look up table such as that provided by the Building Performance Institute: (see 'BPI Distribution Efficiency Table') or by performing duct blaster testing.

[772] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[773] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[774] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

Other factors as defined above.

For example, assuming: HVI_Max_CFM =117; HDD60 = 5,552; HVI_Rated_ASRE = 75%; ηHeat = 0.80 (Non-condensing Gas Heat); Daily_Hrs_Ventilation = 17.8, then

$\Delta Therms_{Annual}$ = 1.08 * 117 * 5,552 * 24 * 75% / 0.80 / 100,000 * 17.8 / 24

= 117 Therms

REVIEW DEADLINE: 1/1/2029

5.3.21 Air Handler Filter Cleaning/Replacement

DESCRIPTION

A dirty air handler filter increases electricity consumption for circulating fans and decreases system heating and cooling efficiencies. This measure characterizes a direct install style program whereby an existing dirty filter is either cleaned or replaced. This measure applies to central forced-air furnaces, central AC and heat pump systems. Where homes do not have central cooling, only the annual heating savings will apply.

This measure was developed to be applicable to the following program types: DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient condition is a cleaned or replaced air handler filter.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is an air handler filter with dirt build up and result in a blower fan motor working harder and the heating/cooling system efficiency degrading.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 3 years[775].

DEEMED MEASURE COST

The actual measure cost to clean or replace the filter should be used. If costs are unavailable assume $30 for a filter clean (assuming ½ hour at $60 an hour) or $50 for a new filter ($20 for the filter plus ½ hour at $60 an hour).

LOADSHAPE

Loadshape R10 - Residential Electric Heating and Cooling

Loadshape R09 - Residential Electric Space Heat

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's Forward Capacity Market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)
= 68%[776]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)
= 46.6%[777]

[775] Consistent with furnace tune-up measure.
[776] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[777] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = kW_{motor} * ((\%ElectricHeat * EFLH_{heat}) + (\%Cool * EFLHcool)) * \%FanSave$$

Where:

kW_{motor} = Average air handler fan motor full load electric demand

= 0.377 kW[778]

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= 0 % for Fossil fuel heating

= If unknown[779], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[780]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

$EFLH_{heat}$ = Equivalent Full Load Hours for heating. Depends on location. See table below:

Climate Zone (City based upon)	EFLH for Furnaces[781]	EFLH for Central Heat Pumps[782]
1 (Rockford)	1022	1924

[778] Typical blower motor capacity for gas furnace is ¼ to ¾ HP. Midpoint is ½ HP. ½ HP × 0.746 (kW/hp)=0.377kW.

[779] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[780] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[781] Full load hours for Chicago, are based on findings in 'Energy Efficiency / Demand Response Nicor Gas Plan Year 1 (6/1/2011-5/31/2012) Research Report: Furnace Metering Study (August 1, 2013), prepared by Navigant Consulting, Inc. Values for other cities are then calculated by comparing relative HDD at base 60F.

[782] Full load heating hours for heat pumps are provided for Rockford, Chicago and Springfield in the ENERGY STAR Calculator. Estimates for the other locations were calculated based on the FLH to Heating Degree Day (from NCDC) ratio. VEIC consider ENERGY STAR estimates to be high due to oversizing not being adequately addressed. Using average Illinois billing data (from ICC Commerce Commission) VEIC estimated the average gas heating load and used this to estimate the average home heating output (using 83% average gas heat efficiency). Dividing this by a typical 36,000 Btu/hr ASHP gives an estimate of average ASHP

Climate Zone (City based upon)	EFLH for Furnaces[781]	EFLH for Central Heat Pumps[782]
2 (Chicago)	976	1726
3 (Springfield)	836	1708
4 (Belleville)	645	1195
5 (Marion)	656	1270
Weighted Average[783]		
ComEd	978	1766
Ameren	800	1547
Statewide	928	1700

%Cool = Fraction of customers with thermostat-controlled air-conditioning

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[784]	98.9%	96.5%	99.8%	98.7%	98.6%

$EFLH_{cool}$ = Equivalent Full Load Hours for cooling. If no cooling, assume 0.

= dependent on location and building type:[785]

Climate Zone (City based upon)	FLHcool (single family)	FLHcool (multifamily)	FLH_cooling (weatherized multifamily)[786]
1 (Rockford)	547	499	320
2 (Chicago)	709	629	403
3 (Springfield)	779	707	453
4 (Belleville)	1,082	982	630
5 (Marion)	956	868	557

FLH_heat of 1821 hours. We used the ratio of this value to the average of the locations using the ENERGY STAR data (1994 hours) to scale down the ENERGY STAR estimates. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of HDD60, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHheat values

[783] Weighting for Ameren is based on gas accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[784] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[785] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[786] *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015. The multifamily units within this study had undergone significant shell improvements (air sealing and insulation) and therefore this set of assumptions is only appropriate for units that have recently participated in a weatherization or other shell program. Note that the FLHcool where recalculated based on existing efficiencies consistent with the TRM rather than from the metering study. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

Climate Zone (City based upon)	FLHcool (single family)	FLHcool (multifamily)	FLH_cooling (weatherized multifamily) [786]
Weighted Average[787]			
ComEd	676	603	386
Ameren	875	791	507
Statewide	731	655	420

%FanSave = Assumed percent fan savings

= 10%[788]

For example, replacing an air handler filter in a home with a gas furnace and central cooling in Chicago:

ΔkWh = 0.377 * (976 + (1 * 709)) * 0.1

= 63.5 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = kW_{motor} * \%AC * \%FanSave * CF$$

Where:

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)

= 68%[789]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during peak period)

= 46.6%[790]

For example, replacing an air handler filter in a home with a gas furnace and central cooling in Chicago:

ΔkW_{SSP} = 0.377 * 1 * 0.1 * 0.68

= 0.0256 kW

FOSSIL FUEL SAVINGS

$$\Delta Therms = \%FossilHeat * Gas_Heating_Consumption * EI$$

Where:

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for Fossil Fuel heating

[787] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[788] Based on Energy.gov website; "Maintaining Your Air Conditioner". Accessed 7/16/2014, which states that replacing a dirty air filter with a clean one can lower total air conditioner energy consumption by 5-15%. Since most savings will be to the fan motor, assuming 10%.

[789] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[790] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

= 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= If unknown[791], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[792]					75.4%

Gas_Heating_Consumption

= Estimate of annual household heating consumption for gas heated single-family homes. If location is unknown, assume the average below[793].

Climate Zone (City based upon)	Gas_Heating_ Consumption (therms)
1 (Rockford)	1,052
2 (Chicago)	1,005
3 (Springfield)	861
4 (Belleville)	664
5 (Marion)	676
Average	955

EI = Estimated savings from efficiency Improvement

= 1%[794]

For example, replacing an air handler filter in a home with a gas furnace and central cooling in Chicago:

ΔTherms = 1.0 * 976 * 0.01

= 9.76 therms

[791] All values except for People's Gas and Northshore Gas are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential baseline Study Results", Oct 31 2024. People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[792] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

[793] Values are based on adjusting the average household heating load (834 therms) for Chicago based on 'Table E-1, Energy Efficiency / Demand Response Nicor Gas Plan Year 1, Research Report: Furnace Metering Study', divided by standard assumption of existing unit efficiency of 83% (estimate based on 24% of furnaces purchased in Illinois were condensing in 2000 (based on data from GAMA, provided to Department of Energy), assuming typical efficiencies: (0.24*0.92) + (0.76*0.8) = 0.83) to give 1005 therms. This Chicago value was then adjusted to a statewide average using relative HDD assumptions to adjust for the evaluation results focus on northern region. Values for individual cities are then calculated by comparing average HDD to the individual city's HDD.

[794] Based on Michael Blasnik estimate of 1% gas savings for 25% air flow change; final slide of presentation: https://buildingscience.com/sites/default/files/01_Lies_Damned_Lies_and_Modeling_rev.pdf

5.3.22 High Efficiency Kitchen Exhaust Fans

DESCRIPTION

This measure will serve to capture the savings from the installation of a new kitchen exhaust fan, also known as a Range Hood, for typical usage. Existing kitchen exhaust fans may be too noisy, inefficient, or in need of replacement if beyond repair. This measure assumes fan capacities between 10 and 200 CFM rated at a sound level of maximum 2.0 sones at 0.1 inches of water column static pressure. All eligible installations shall be sized to provide the mechanical ventilation rate indicated by ASHRAE 62.2.

This measure was developed to be applicable to the following program types: TOS, NC, RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

New efficient ENERGY STAR[795] exhaust-only ventilation fan, quiet (≤ 2.0 sones) operating in accordance with recommended ventilation rate indicated by ASHRAE 62.2 – 2016. ENERGY STAR specifications (effective October 1, 2015) are provided below:

Efficiency Level	Fan Capacity	Minimum Efficacy Level (CFM/Watts)	Maximum Allowable Sound Level (sones)
ENERGY STAR	≤ 75 W	2.8	2.0

DEFINITION OF BASELINE EQUIPMENT

New standard efficiency exhaust-only ventilation fan.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 19 years.[796]

DEEMED MEASURE COST

Incremental cost per installed fan is $107.[797]

LOADSHAPE

Loadshape R11 - Residential Ventilation

COINCIDENCE FACTOR

N/A

[795] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[796] Conservative estimate based upon GDS Associates Measure Life Report "Residential and C&I Lighting and HVAC measures" 25 years for whole-house fans, and 19 for thermostatically-controlled attic fans.
[797] Analysis using cost data collected from online resources. See 'Kitchen Exhaust Fans Supplementary Data' workbook for more information.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (CFM * (1/\eta_{,BASELINE} - 1/\eta_{EFFICIENT})/1000) * Hours$$

Where:

CFM = Nominal Capacity of the exhaust fan
= Actual or use defaults provided below

$\eta_{BASELINE}$ = Average efficacy for baseline fan (CFM/watts)
= Actual or use defaults provided below

$\eta_{EFFCIENT}$ = Average efficacy for efficient fan (CFM/watts)
= Actual or use defaults provided below

Hours = assumed annual run hours of stove
= 120[798]

Defaults provided below:[799]

[798] Assumes that 50% of cooking events utilize the kitchen exhaust fan. Number of cooking events is consistent with the 5.1.14 Residential Induction Cooktop measure which assumes 1 hours per cycle and 239 cycles per year therefore 239 operating hours per year. 239 cycles per year is based on a 2016 CASE study for PG&E modeling Plug Loads.
[799] Average CFM and EnergyStar CFM/Watts calculated using EnergyStar's list of qualified products, accessed 5/2023.
[800] Based on review of Range Hood products available on CEC Appliance Database, accessed 5/12/2023. See 'Kitchen Exhaust Fans Supplementary Data' spreadsheet, "All Fans less than 75W" tab for more details.

5.3.23 Residential Gas Heat Pump

DESCRIPTION

Heat pumps generally involve the use of a refrigerant and operate based on a refrigeration cycle to produce heating effect as energy output[801]. An electric compressor for energy output drives traditional electric heat pump operation. Gas-powered heat pumps (GHP) are a subset of heat pumps whose operation is driven by a gaseous fuel, instead of an electrically driven compressor for energy output. This measure addresses the installation of factory-made gas heat pumps that use natural gas as the primary fuel. GHPs can be separated into two categories: work-activated technologies, where a delivered fuel drives a prime mover (e.g., internal combustion engine) which supplies work to a refrigerant compressor, and heat-activated, where the primary energy input to the heat pump cycle is thermal energy, often from fuel combustion, driving a sorption-type or other thermally-driven heat pump cycle. This measure protocol applies specifically to heat-activated sorption-type gas GHPs. The measure applies to single and multifamily (in-unit) residential applications for space heating and combination ("Combi") type applications with combined space heating and domestic hot water (DHW) heating operation. For centrally heated multifamily applications, refer to measure "4.4.55 Commercial Gas Heat Pump". This measure characterizes the installation of a residential gas-powered heat pump for the following scenarios: NC, TS, and EREP.

The measure will focus on the following cases:

New Construction: The installation of a GHP system certified to ANSI Z21.40.1 or ANSI Z21.40.2, respectively, that meets the criteria laid out in ANSI Z21.40.4 performance testing and rating of gas-fired, air Conditioning, and heat Pump Appliances and meets the Coefficient of Performance (COP) requirements outlined in this measure in place of standard baseline equipment during the construction of a new building or a major renovation. This will focus on energy savings by adding GHP equipment during the construction of the new residence.

Time of Sale: The installation of the GHP system meeting the Coefficient of Performance (COP) requirements outlined in this measure, replacing an existing baseline system at the end of its useful life, or installing a new GHP system in a new home. This will focus on energy savings by adding a GHP to replace existing space heating equipment at the end of its life.

Early Replacement: The early removal of existing functioning baseline system prior to the end of its effective useful life, for installation of a GHP system meeting the COP requirements outlined in this measure. This will focus on energy savings through addition of GHP equipment at an existing residence where the existing space heating equipment has not reached the end of their useful life.

DEFINITION OF EFFICIENT EQUIPMENT

For all measure cases the efficient equipment is a residential GHP with an input rating of less than 225,000 Btu/hr for both space heating application, and combi applications (space heat and domestic water heating). Since gas heat pumps do not have a U.S. DOE federal standard test procedure, coefficient of performance should be based on ANSI Z21.40.4 test conditions at 7°F DB/ 5.5°F WB outdoor air and 95°F return water temperature.

DEFINITION OF BASELINE EQUIPMENT

Baseline equipment for all measure cases, defined for both space heating and combi applications are as follows:

New Construction: To calculate savings with a central furnace baseline, the baseline equipment is a natural gas-fired furnace with minimum Annual Fuel Utilization Efficiency (AFUE) as required by federal standards[802], 80% AFUE for a non-weatherized furnace. To calculate savings with an electric baseline, the baseline equipment is assumed to be an

[801] While most heat pump equipment can also be used for cooling applications, this measure is applicable to gas-fired heat pumps for space heating, domestic water heating and combination (space heating and domestic water heating combined) applications.
[802] Federal minimum AFUE requirement for residential furnaces. eCFR :: 10 CFR Part 430 Subpart C -- Energy and Water Conservation Standards

Air Source Heat Pump meeting the Federal Standard Efficiency level[803] , 14.3 SEER2, and 7.5 HSPF2. Note the baseline in this case should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition. For space heating, if the baseline is unknown, then it is assumed to be a gas furnace compliant with the federal minimum standards. For combi application, if the baseline is unknown, then it is assumed to be a gas furnace and a gas storage water heater compliant with the federal minimum standards.

Time of Sale: The baseline for this measure is a new replacement unit of the same system type as the existing unit, meeting the baselines provided below[804].

Unit Type	Efficiency Standard
Standard sized Ducted ASHP	14.3 SEER2, 9.4 EER2, 7.5 HSPF2
Standard sized Ductless ASHP	14.3 SEER2, 8.5 EER2, 7.5 HSPF2
Space constrained ASHP	11.9 SEER2, 7.8 EER2, 6.3 HSPF2
Room AC (baseline for portable HP only)	Select appropriate baseline from measure 5.1.7. Assume same capacity as efficient.
Electric Resistance (default for portable HP)	3.412 HSPF2
Natural Gas or LP Furnace	80% AFUE
Natural Gas or LP Boiler	84% AFUE
Oil Furnace	83% AFUE
Oil Boiler	86% AFUE
Standard sized Central AC	13.4 SEER2, 10.6 EER2
Space constrained Central AC	11.7 SEER2, 9.2 EER2

[803] Federal minimum requirement for residential furnaces. eCFR :: 10 CFR Part 430 Subpart C -- Energy and Water Conservation Standards

[804] Federal Standard as provided in DOE 10 CFR 430.32.

The baseline condition for water heating is a new water heater meeting federal minimum efficiency standards, dependent on the storage volume (in gallons) of the water heater. Note the baseline in this case should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition. If the baseline is unknown, then it is assumed to be a gas storage water heater type compliant with the federal minimum standards.

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[805]
Residential Electric Storage Water Heaters ≤ 75,000 Btu/h	≤55 gallon tanks	Very small	UEF = 0.8808 – (0.0008 * Rated Storage Volume in Gallons)
		Low	UEF = 0.9254 – (0.0003 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.9307 – (0.0002 * Rated Storage Volume in Gallons)
		High	UEF = 0.9349 – (0.0001 * Rated Storage Volume in Gallons)
	>55 gallon and ≤120 gallon tanks [806]	Very small	UEF = 1.9236 – (0.0011 * Rated Storage Volume in Gallons)
		Low	UEF = 2.0440 – (0.0011 * Rated Storage Volume in Gallons)
		Medium	UEF = 2.1171 – (0.0011 * Rated Storage Volume in Gallons)
		High	UEF = 2.2418 – (0.0011 * Rated Storage Volume in Gallons)
Residential Electric Instantaneous Water Heaters	≤12kW and ≤2 gal	All other	UEF = 0.91
		High	UEF = 0.92
Residential Gas Storage Water Heaters ≤75,000 Btu/h	≤55 gallon tanks	Very small	UEF = 0.3456 – (0.0020 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5982 – (0.0019 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6483 – (0.0017 * Rated Storage Volume in Gallons)
		High	UEF = 0.6920 – (0.0013 * Rated Storage Volume in Gallons)
	>55 gallon and ≤100 gallon tanks	Very small	UEF = 0.6470 – (0.0006 * Rated Storage Volume in Gallons)
		Low	UEF = 0.7689 – (0.0005 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.7897 – (0.0004 * Rated Storage Volume in Gallons)
		High	UEF = 0.8072 – (0.0003 * Rated Storage Volume in Gallons)
Residential Gas Fired Instantaneous Water Heaters	< 2 gal and >50,000 Btu/h	Very small	UEF = 0.80
		All other	UEF = 0.81
Residential Oil Storage Water Heater	≤50 gallon tanks	Very small	UEF = 0.2509 − (0.0012 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5330 − (0.0016 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6087 − (0.0016 * Rated Storage Volume in Gallons)
		High	UEF = 0.6815 − (0.0014 * Rated Storage Volume in Gallons)

Draw patterns are based on first hour rating (gallons) for storage tanks and maximum flow (GPM) for instantaneous as shown below:[807]

Storage Water Heater Draw Pattern	
Draw Pattern	**First Hour Rating (gallons)**
Very Small	≥ 0 and < 18
Low	≥ 18 and < 51
Medium	≥ 51 and < 75
High	≥ 75

Instantaneous Water Heater Draw Pattern	
Draw Pattern	**Max GPM**
Very Small	≥ 0 and < 1.7

[805] All Residential sized Federal Standards are from DOE Standard 10 CFR 430, Residential-Duty and Commercial Federal Standard are from DOE Standard 10 CFR 431.
[806] It is assumed that tanks <75,000Btu/h and >55 gallons will not be eligible measures due to the high baseline.
[807] Definitions provided in 10 CFR 430, Subpart B, Appendix E, Section 5.4.1.

Instantaneous Water Heater Draw Pattern	
Draw Pattern	**Max GPM**
Low	≥ 1.7 and < 2.8
Medium	≥ 2.8 and < 4
High	≥ 4

Early Replacement: The baseline for this measure is the efficiency of the existing heating equipment for the assumed remaining useful life of the existing unit and a new baseline heating system for the remainder of the measure's life. The baseline for an EREP measure is the efficiency of the existing space heating and water heating equipment (if installed in a combi application) for the remainder of its useful life, and the new federal minimum standard for the remainder of the new, efficient equipment's life as specified in the TOS section.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected life is assumed to be 15 years[808].

The remaining life of existing equipment is assumed to be 6 years for ASHP, 7 years for furnace, 8 years for boilers,[809] and 16 years for electric resistance[810]. For example, for a natural gas-fired furnace post the effective useful life of the existing equipment, the second baseline efficiency will be set as required by applicable federal standards[811]. Remaining life of existing gas storage and instantaneous water heaters is assumed to be 4.8 and 6.7 years, respectively.[812]

DEEMED MEASURE COST

New Construction and Time of Sale: For space heating, the actual installed cost of the gas heat pump should be used minus the assumed installation cost of the baseline equipment from table below for electric equipment, or assume $4,019 for a new baseline 80% AFUE furnace or $8,820 for a new baseline 84% AFUE boiler.[813]

Baseline Equipment Type	Capacity Range	Baseline Cost per Ton[814]
Centrally Ducted Air Source Heat Pumps	< 2 tons	$4,602
	≥ 2 to < 3 tons	$3,691
	≥ 3 to < 4 tons	$3,093
	≥ 4 tons	$2,992
Ductless Minisplit Heat Pumps	< 1 ton	$8,156
	≥ 1 to < 2 tons	$5,356
	≥ 2 to < 3 tons	$3,704
	≥ 3 tons	$3,670
Central Air Conditioning	< 2 tons	$2,340
	≥ 2 to < 3 tons	$1,900
	≥ 3 tons	$1,500

[808] U.S. Energy Information Administration | Assumptions to the Annual Energy Outlook 2021. https://www.eia.gov/outlooks/aeo/assumptions/pdf/residential.pdf

[809] Assumed to be one third of effective useful life of replaced equipment.

[810] Assume full measure life (16 years) for replacing electric resistance as we would not expect that resistance heat would fail during the lifetime of the efficient measure.

[811] Federal minimum AFUE requirement for residential furnaces. eCFR :: 10 CFR Part 430 Subpart C -- Energy and Water Conservation Standards

[812] Assumed to be one third of effective useful life.

[813] In 2025, a working group was created to update costs for residential HVAC equipment. Heat Pump and Central Air Conditioning costs are based upon Ameren program data. Furnace and Boiler costs are based on Ameren, Nicor, People's Gas, and North Shore Gas program data. Baseline costs have been determined using ratios from Updated Buildings Sector Appliance and Equipment Costs and Efficiencies by Guidehouse and Leidos, prepared for the U.S. Energy Information Administration, March 2023. See file "HVAC Costs – 071825_VEIC.xlsx" for more details.

[814] Ibid

For combi installations, the full installation cost of a baseline water heater should be added to the above installation cost for space heating with baseline equipment. Defaults are provided below.[815] Actual efficient costs can also be used although care should be taken as installation costs can vary significantly due to complexities of a particular site.

Water Heater Type	Baseline Installed Cost	Deferred Baseline Replacement Cost[816]
Electric Resistance	$1,078	$1,162
Gas-Fired	$1,397	$1,507

Early Replacement: The actual full installation cost of the gas heat pump should be used. If the installation cost of the efficient gas-fired heat pump is unknown, assume the following:

GHP Installation Types	Installed Cost ($/unit) [817]
Space Heating Equipment & Labor	$27,000
Combi Equipment & Labor	$33,754

The assumed deferred cost (after the appropriate number of years described above in the 'Deemed Lifetime of Efficient Equipment' section) of replacing existing equipment with a new baseline unit is presented in the table below for electric equipment, or assume $4,601 for a new baseline 80% AFUE furnace or $10,563 for a new baseline 84% AFUE boiler.[818] This future cost should be discounted to present value using the nominal societal discount rate.

Equipment Type	Capacity Range	Deferred Baseline Cost per Ton
Centrally Ducted Air Source Heat Pumps	< 2 tons	$5,268
	≥ 2 to < 3 tons	$4,226
	≥ 3 to < 4 tons	$3,541
	≥ 4 tons	$3,425
Ductless Minisplit Heat Pumps	< 1 ton	$9,337
	≥ 1 to < 2 tons	$6,132
	≥ 2 to < 3 tons	$4,240
	≥ 3 tons	$4,202
Central Air Conditioning	< 2 tons	$2,679
	≥ 2 to < 3 tons	$2,175
	≥ 3 tons	$1,717

[815] RS MEANS 2025 data for Chicago, IL. Costs shown are average of minimum and maximum values for "Residential Appliances, electric/ gas, glass lined, 30gal". See reference document "RS MEANS – water heater costs.xlsx"

[816] The baseline full cost is inflated applying an inflation rate of 1.91% for 4 years. See reference document "RS MEANS – water heater costs.xlsx"

[817] Based on ongoing field demonstrations done by GTI Energy. These costs are based on actual equipment and installation costs from multiple field demonstrations in the 2024-25 heating season. The following costs and equipment make up the gas heat pump system: Gas Heat pump ($9,055), Air Handler Unit ($4,415), Indirect Storage Tank for Combi systems ($2,360).

[818] All baseline replacement costs are consistent with their respective measures and include inflation rate of 2.28%.

Algorithm

CALCULATION OF ENERGY SAVINGS

Energy savings algorithms for residential GHPs were developed for calculating space heating, and space heating with water heating (combi) applications.

ELECTRIC ENERGY SAVINGS AND FOSSIL FUEL SAVINGS

Non-fuel switch measures:

Space Heating Only Savings:

$$\Delta Therms = \Delta Therms_{SPACE\ HEAT}$$

$$\Delta Therms_{SPACE\ HEAT} = (EFLH_{gasheat} * Capacity * (1/Efficiency_{Base} - 1/Efficiency_{EE})) / 100{,}000$$

Where:

$EFLH_{gasheat}$ = Equivalent Full Load Hours for gas heating

Climate Zone (City based upon)	EFLH[819]
1 (Rockford)	1,022
2 (Chicago)	976
3 (Springfield)	836
4 (Belleville)	645
5 (Marion)	656
Weighted Average[820]	
ComEd	978
Ameren	800
Statewide	928

Capacity = Nominal Heating Output Capacity Size (Btu/hr) for efficient unit

= Actual

$Efficiency_{Base}$ = Baseline Efficiency Rating

= For NC and TOS, use the efficiencies from Table 1[821]

[819] Full load hours for Chicago, are based on findings in 'Energy Efficiency / Demand Response Nicor Gas Plan Year 1 (6/1/2011-5/31/2012) Research Report: Furnace Metering Study (August 1, 2013), prepared by Navigant Consulting, Inc. Values for other cities are then calculated by comparing relative HDD at base 60°F.

[820] Weighting for Ameren is based on gas accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[821] Federal Standard as provided in DOE 10 CFR 430.32

= For EREP, use Actual Annual Fuel Utilization Efficiency Rating if known, for the remainder of equipments useful life

= Use actual AFUE rating where it is possible to measure or reasonably estimate. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[822] or if unknown, assume 64.4 AFUE%[823] for furnaces and 61.6 AFUE%[824] for boilers. If unknown value is used, it should not be derated by age.

$Efficiency_{EE}$ = Rated Gas Heat Pump space heating efficiency, expressed as a fuel-input only COP_{Gas} for nominal capacity rating condition

100,000 = Converts Btu to Therms

Space Heating and Domestic Hot Water (Combi) Savings:

$$\Delta Therms = \Delta Therms_{SPACE\ HEAT} + \Delta Therms_{DHW}$$

Please refer to the section above for the algorithm to calculate $\Delta therms_{SPACE\ HEAT}$

Please refer to the section below for the algorithm to calculate $\Delta therms_{DHW}$

$$\Delta Therms_{DHW} = \frac{(T_{out} - T_{in}) \ * \ GPD * Household * 365.25 * \gamma Water * 1.0 * \left(\frac{1}{TE_{base}} - \frac{1}{COP_{Eff}}\right)}{100{,}000}$$

Where:

T_{OUT} = Tank temperature
= If unknown, assume default value of 125°F

T_{IN} = Incoming water temperature from well or municipal system
= If unknown, assume default value of 50.7°F[825]

γWater = Specific weight capacity of water (lb/gal)

= 8.33 lbs/gal

1.0 = Specific heat of water (Btu/lb·°F)

100,000 = Converts Btu to Therms

$TE_{gasbase}$ = Rated efficiency of baseline water heater (expressed as Uniform Energy Factor (UEF) or Thermal Efficiency. For NC and TOS, refer to the table in DEFINITION OF BASELINE EQUIPMENT section)

= For EREP, use Actual UEF or Thermal Efficiency if known, for the remainder of equipments useful life

COP_{Eff} = Rated efficiency of the GHP as certified expressed as Coefficient of Performance

[822] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).
[823] Average nameplate efficiencies of all Early Replacement qualifying equipment in Ameren PY3-PY4.
[824] Ibid
[825] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

365.25 = Days per year

GPD = Gallons Per Day of hot water use per person
= 45.5 gallons hot water per day per household/2.59 people per household [826]

= 17.6 gallons

Household = Average number of people per household

Household Unit Type	Household[827]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[828]
Custom	Actual Occupancy or Number of Bedrooms[829]		

Note the same draw pattern (very small, low, medium, and high draw) should be used for both baseline and efficient units.

Example:

A single family home in Chicago is replacing the existing space heating and water heating baseline equipment with an 80,000 Btu/hr output gas heat pump system rated for a COP of 1.3. The baseline equipment being replaced is gas furnace and a gas-fired storage hot water heater. Measure type is TOS.

Baseline equipment efficiency: Gas furnace – 80% AFUE; Gas-fired storage hot water heater – 0.78 TE for a high draw pattern and 80 gallon tank.

$$\Delta therms = \Delta therms_{SPACE\ HEAT} + \Delta therms_{DHW}$$

$$\Delta therms_{SPACE\ HEAT} = (EFLH_{gasheat} * Capacity * ((1/Efficiency_{Base} – 1/Efficiency_{EE})) / 100{,}000$$

$$= (976 * 80{,}000 * ((1/0.80 – 1/1.3)) / 100{,}000$$

$$= 375 \text{ therms}$$

$$\Delta therms_{DHW} = (T_{out} – T_{in}) * GPD * Household * 365.25 * \text{ɣ}Water * 1.0 * (1/TE_{base} – 1/COP_{Eff}))/100{,}000$$

$$= ((125 – 50.7) * 17.6 * 2.67 * 365.25 * 8.33 * 1.0 * (1/0.78 – 1/1.3))/100{,}000$$

$$= 54 \text{ therms}$$

Total Therm Savings = 375 + 54
= 429 therms

[826] Deoreo, B., and P. Mayer. Residential End Uses of Water Study Update. Forthcoming. ©2015 Water Research Foundation. Reprinted With Permission.
[827] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.
[828] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.
[829] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

Fuel switch measures:

Fuel switch measures must produce positive total lifecycle energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows: (note for early replacement measures that the lifetime savings should be calculated by calculating savings for the remaining useful life of the existing equipment and for the remaining measure life):

SiteEnergySavings (MMBTUs) = (ElectricHeatReplaced - $GHPEnergyConsumed_{Heat}$)+ (ElectricWaterHeatReplaced – $GHPEnergyConsumed_{DHW}$)

If SiteEnergySavings calculated above is positive, the measure is eligible.

Electric Space Heating Replaced with GHP (Space Heating Application)

ElectricHeatReplaced [$MMBTU_{source}$] = ($Capacity_{heat}$ * $EFLH_{electricheat}$ * (1/COP_{base})) / 1,000

$GHPEnergyConsumed_{Heat}$ [$MMBTU_{source}$] = (($Capacity_{heat}$ * $EFLH_{gasheat}$ * (1/COP_{GHP})) / 1,000)

Where:

$Capacity_{heat}$ = Nominal heating output capacity of the efficient equipment in kBtu per hour (1 ton of heating capacity equals 12 kBtu/hr).

COP_{base} = Coefficient of performance of the baseline equipment, or thermal efficiency if applicable, at nominal condition

$EFLH_{electricheat}$ = Heating Equivalent Full Load Hours for electric heating[830]

Climate Zone (City based upon)	FLH_heat
1 (Rockford)	1,924
2 (Chicago)	1,726
3 (Springfield)	1,708
4 (Belleville)	1,195
5 (Marion/Murphysboro)	1,270
Weighted Average[831]	
ComEd	1,766
Ameren	1,547
Statewide	1,700

$EFLH_{gasheat}$ = Heating Equivalent Full Load Hours for gas heating

= See previous section

COP_{GHP} = Coefficient of performance of the GHP equipment
= Actual installed

[830] Heating EFLH based on ENERGY STAR EFLH for Rockford, Chicago, and Springfield and on NCDC/NOAA HDD for the other two cities. In all cases, the hours were adjusted based on average natural gas heating consumption in IL.
[831] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

Electric Water Heating Replaced with GHP (Combi Application)

ElectricWaterHeatReplaced [$MMBTU_{site}$] = ((T_{out}-T_{in}) * $GPD * Household * 365.25$ * γWater * 1.0 * ($1/TE_{elecbase}$)) /1,000,000

$GHPEnergyConsumed_{DHW}$ [$MMBTU_{site}$] = (T_{out}-T_{in}) * $GPD * Household * 365.25$ * γWater * 1.0 * ($1/COP_{GHP}$) / 1,000,000)

**See previous sections for most descriptions

$TE_{elecbase}$ = Rated efficiency of baseline water heater expressed as Uniform Energy Factor (UEF) or Thermal Efficiency (TE) or Coefficient of Performance (COP)

COP_{GHP} = Coefficient of performance of the GHP equipment
= Actual installed

Total Therm Savings = SiteEnergySavings * 10

Example:

A single family home in Chicago is replacing the existing space heating and water heating baseline equipment with an 80,000 Btu/hr output gas heat pump system rated for a COP of 1.3. The baseline equipment being replaced is an electric baseboard and an electric resistance storage hot water heater. Measure type is EREP.

Baseline equipment efficiency: electric baseboard – 1.0 COP; Electric Resistance storage hot water heater – 0.95 TE for a 50 gallon gallon tank.

$$\Delta therms = \Delta therms_{SPACE\ HEAT} + \Delta therms_{DHW}$$

$\Delta therms_{SPACE\ HEAT} = (EFLH_{gasheat} * Capacity_{heat} * (1/Efficiency_{Base} – 1/Efficiency_{EE})) / 100,000$

= (976 * 80,000 * (1/1.0 – 1/1.30)))) / 100,000

= 180 therms

$\Delta therms_{DHW} = (T_{out} – T_{in}) * GPD * Household * 365.25 * ɣWater * 1.0 * (1/TE_{base} – 1/COP_{Eff}))/100,000$

= ((125 – 50.7) * 17.6 * 2.67 * 365.25 * 8.33 * 1.0 * (1/0.95 – 1/1.3))/100,000

= 30 therms

Total Therm Savings = 180 + 30

= 210

= 264 therms

REVIEW DEADLINE: 1/1/2029

5.4 Hot Water End Use

5.4.1 Domestic Hot Water Pipe Insulation

DESCRIPTION

This measure describes adding insulation to un-insulated domestic hot water pipes. The measure assumes the pipe wrap is installed either to the first length of both the hot and cold pipe (this is the most cost-effective section to insulate in non-circulating systems, since the water pipes act as an extension of the hot water tank) or to a hot water recirculating loop. Insulating this length therefore helps reduce standby losses. Default savings are provided per 3ft length and are appropriate up to 6ft of the hot water pipe and 3ft of the cold. Where a hot water recirculating pump is in use, this measure is viable for the entire hot water loop.

This measure was developed to be applicable to the following program types: TOS, NC, RF, KITS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient case is installing pipe wrap insulation to a length of hot water pipe.

DEFINITION OF BASELINE EQUIPMENT

The baseline is an un-insulated hot water pipe.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 12 years.[832]

DEEMED MEASURE COST

The actual installation cost should be used if known. If unknown, the measure cost including material and installation is assumed to be $3 per linear foot.[833] For foam pipe insulation assume a measure cost of $0.26/ft for ½" insulation and $0.31/ft for ¾" insulation.[834]

LOADSHAPE

Loadshape C53 - Flat

COINCIDENCE FACTOR

This measure assumes a flat loadshape since savings relate to reducing standby losses and as such the coincidence factor is 1.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \%Electric_DHW * ((1 / R_{exist} - 1 / R_{new}) * C_{inside} * L_{effective} * \Delta T * 8{,}766 * ISR) / \eta DHW / 3{,}412$$

Where:

%Electric_DHW = Percentage of DHW savings assumed to be electric

= 100 % for Electric

[832] . California DEER EUL Table Update 2014-02-05. Average of values for electric DHW (13 years) and gas DHW (11 years).
[833] Consistent with DEER 2008 Database Technology and Measure Cost Data (www.deeresources.com).
[834] Review of website cost data for Homedepot.com, Lowes.com, and Menards.com for locations in Peoria, IL.

= 0 % for Fossil Fuel

= If unknown[835], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	19.7%	30.6%	63.3%	67.3%	31.4%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
People's Gas	2.1%	2.0%	1.7%	2.4%	2.2%
Northshore Gas	1.5%	1.8%	10.0%	2.4%	2.4%
Nicor Gas	7.6%	9.9%	14.4%	22.6%	10.0%
All DUs[836]					**29%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

R_{exist} = Pipe heat loss coefficient of uninsulated pipe (existing) [(hr-°F-ft)/Btu]

= Varies based on pipe size and material. See table below for values.

R_{new} = Pipe heat loss coefficient of insulated pipe (new) [(hr-°F-ft)/Btu]

= Actual (R_{exist} + R value of insulation[837])

C_{inside} = Inside circumference of the pipe [ft]

= Actual (0.5" pipe = 0.1427 ft, 0.75" pipe = 0.2055 ft); See table below for values.

$L_{effective}$ = Effective length of pipe from water heating source covered by pipe insulation (ft) [838]

= $L_{Horizontal} + \alpha L_{Vertical}$

= Actual; See table below for α values. If unknown, assume 3ft of vertical and remaining horizontal.

ΔT = Average temperature difference between supplied water and outside air temperature (°F)

= 60°F [839]

8,766 = Hours per year

[835] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[836] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[837] Where possible it should be ensured that the R-value of the insulation is at the appropriate mean rating temperature (100F).

[838] In cases with zero wind, heat loss (and therefore) savings is larger from horizontal pipe configurations than vertical pipe configurations due, perhaps to the way in which convective losses are handled. Given that most DHW pipe insulation installations begin with a vertical orientation from the water heater, an adjustment to the engineering calculation is needed. An analysis of the 3E PLUS tool by NAIMA (https://insulationinstitute.org/tools-resources/free-3e-plus/) yielded adjustment factors for horizontal to vertical loss and savings values. See DHW_PipeInsulationCalcs_062121.xlsx for details of the analysis and comparisons.

[839] Assumes 125°F water leaving the hot water tank and average temperature of basement of 65°F.

ISR = In Service Rate

= 0.50 for Kits distribution[840], 0.78 for Virtual Assessment followed by Self-Installation[841], and 1.0 for Direct Install, TOS, or Verified Install program types

ηDHW = Recovery efficiency of electric hot water heater

= 0.98 [842]

3412 = Conversion from Btu to kWh

Parameter assumptions for various pipe sizes and materials:

Type and Size	C_{inside}[843] (I.D.*π/12) (ft)	Product of Overall Heat Transfer Coefficient and Pipe Area (UA) per foot[844] from bare pipe (BTU/hr·ft·°F)	Pipe Area per linear foot (ft^3)[845]	R_{exist} ((hr·ft·°F)/BTU)	Horizontal to Vertical Adjustment Factor (α)
½" Copper Pipe	0.1427	0.345	0.153	0.444	0.67
¾" Copper Pipe	0.2055	0.417	0.217	0.521	0.72
½" PEX	0.1270	0.438	0.145	0.332	0.73
¾" PEX	0.1783	0.545	0.204	0.374	0.77

For example, insulating 6 feet of 0.75" copper pipe (4ft vertical + 2ft horizontal) with R-5 wrap for electric DHW through a Direct Install program:

$\Delta kWh = \%Electric_DHW * (((1 / R_{exist} - 1 / R_{new}) * C_{inside} * L_{effective} * \Delta T * 8{,}766 * 1.0) / \eta DHW) / 3{,}412$

$= 1 * (((1/0.521 - 1/3.521) * 0.2055 * (2 + 4 * 0.72) * 60 * 8{,}766 * 1.0) / 0.98)/3{,}412$

$= 258$ kWh

The following table provides annual energy savings per foot of pipe insulation for various configurations with electric DHW:

[840] Results from Home Energy Worksheets completed by student/families in 2020, 2021, and 2022 were nearly the same as values from: 2020 survey research by Guidehouse, conducted with Peoples Gas income qualified recipients of self-install efficiency kits distributed by mail in late 2019 (with 117 survey respondents) and research from 2021 Ameren Illinois Income Qualified participant survey, available on IL SAG website: https://ilsag.s3.amazonaws.com/AIC-Income-Qualified-Initiative-Participant-Survey-Results-Memo-FINAL-2022-02-01.pdf. Home Energy Worksheets also establish the fraction of participants who indicate they "will install later" for specific measures. Follow-up research completed by Guidehouse for Nicor Gas in 2022 found that, on average, 51.3% of respondents who initially reported that they hadn't installed specific kit measures, but "planned to" subsequently had installed the measures. Combining these findings allows for an ISR that accounts for initial and one round of subsequent installations. To maintain a conservative estimate of ISR, the remaining 48.7% are presumed uninstalled. See: EESchoolKitSubsequentInstall_HEW.xlsx for data and calculations.

[841] An equal weighted average of Direct Install and Kit ISRs. Interest and applicability of measures confirmed through virtual assessment followed by self-installation without verification of install.

[842] Electric water heaters have recovery efficiency of 98%.

[843] See: https://energy-models.com/pipe-sizing-charts-tables (last accessed 5/7/21) for copper pipe sizes and https://www.garagesanctum.com/size-chart/pex-tubing-size-chart/ (last accessed 5/7/21) for PEX pipe sizes.

[844] Laboratory measured values from Hoeschele and Weitzel (2012), Figure 1.

[845] Calculated using the average pipe thickness (I.D. + O.D.)*0.5.

	ΔkWh Savings per Foot of Insulation (kWh/ft)	
Measure Configuration	**Kit Distribution (ISR = 50%)**	**All Other Programs (ISR = 100%)**
Horizontal Pipe Orientation		
½" Copper Pipe insulated with R-3, ½" thick insulation	22	44.0
¾" Copper Pipe insulated with R-3, ½" thick insulation	26.5	52.9
½" PEX insulated with R-3, ½" thick insulation	27.1	54.2
¾" PEX insulated with R-3, ½" thick insulation	33.4	66.7
Vertical Pipe Orientation		
½" Copper Pipe insulated with R-3, ½" thick insulation	14.8	29.5
¾" Copper Pipe insulated with R-3, ½" thick insulation	19.1	38.1
½" PEX insulated with R-3, ½" thick insulation	19.8	39.5
¾" PEX insulated with R-3, ½" thick insulation	25.7	51.3
Unknown		
R-3, ½" thick insulation for ½" pipes – pipe type and configuration unknown (average of vertical and horizontal configurations for ½"pipe)	20.9	41.8
R-3, ½" thick insulation for ¾" pipes – pipe type and configuration unknown (average of vertical and horizontal configurations for ¾"pipe)	26.1	52.2
Unknown pipe type (straight average) and configuration (average of all vertical and horizontal configurations) insulated with R-3, ½" thick insulation	23.5	46.9

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh / 8766$$

Where:

ΔkWh = kWh savings from pipe wrap installation

8766 = Number of hours in a year (since savings are assumed to be constant over year).

For example, insulating 6 feet of 0.75" copper pipe (4ft vertical + 2ft horizontal) with R-5 wrap through a Direct Install program:

$$\Delta kW = 258/8766$$
$$= 0.0294kW$$

The following table provides peak demand savings per foot of pipe insulation for various configurations with electric DHW:

Measure Configuration	ΔkW Savings per Foot of Insulation (kW/ft)	
	Kit Distribution (ISR = 50%)	All Other Programs (ISR = 100%)
Horizontal Pipe Orientation		
½" Copper Pipe insulated with R-3, ½" thick insulation	0.0025	0.0050
¾" Copper Pipe insulated with R-3, ½" thick insulation	0.0030	0.0060
½" PEX insulated with R-3, ½" thick insulation	0.0031	0.0062
¾" PEX insulated with R-3, ½" thick insulation	0.0038	0.0076
Vertical Pipe Orientation		
½" Copper Pipe insulated with R-3, ½" thick insulation	0.0017	0.0034
¾" Copper Pipe insulated with R-3, ½" thick insulation	0.0022	0.0043
½" PEX insulated with R-3, ½" thick insulation	0.0023	0.0045
¾" PEX insulated with R-3, ½" thick insulation	0.0030	0.0059
Unknown		
R-3, ½" thick insulation for ½" pipes – pipe type and configuration unknown (average of vertical and horizontal configurations for ½"pipe)	0.0024	0.0048
R-3, ½" thick insulation for ¾" pipes – pipe type and configuration unknown (average of vertical and horizontal configurations for ¾"pipe)	0.0030	0.0060
Unknown pipe type (straight average) and configuration (average of vertical and horizontal configurations for all pipes) insulated with R-3, ½" thick insulation	0.0027	0.0053

FOSSIL FUEL SAVINGS

For Natural Gas DHW systems:

$$\Delta Therm = \%Fossil_DHW * (((1 / R_{exist} - 1 / R_{new}) * C_{inside} * L_{effective} * \Delta T * 8{,}766 * ISR) / \eta DHW) / 100{,}000$$

Where:

%Fossil_DHW = Percentage of DHW savings assumed to be fossil fuel

= 100 % for Fossil Fuel

= 0 % for Electric

= If unknown[846], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%

[846] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

	Location				
Utility	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs[847]					**71%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

ηDHW = Recovery efficiency of fossil hot water heater

= 0.78 [848]

Other variables as defined above

For example, insulating 6 feet of 0.75" copper pipe (4ft vertical + 2ft horizontal) with R-5 wrap for Gas DHW through a Direct Install program:

$\Delta Therm = \%Fossil_DHW * (((1 / R_{exist} - 1 / R_{new}) * C_{inside} * L_{effective} * \Delta T * 8{,}766 * ISR) / \eta DHW) /100{,}000$

$= 1 * (((1/0.521 - 1/3.521) * 0.2055 * (2 + 4 * 0.72) * 60 * 8766 * 1.0) / 0.78 / 100{,}000$

= 11.06 therms

The following table provides Natural Gas savings per foot of pipe insulation for various configurations for natural gas DHW:

	ΔTherm Savings per Foot of Insulation (Therms/ft)	
Measure Configuration	Kit Distribution (ISR = 50%)	All Other Programs (ISR = 100%)
Horizontal Pipe Orientation		
½" Copper Pipe insulated with R-3, ½" thick insulation	0.95	1.89
¾" Copper Pipe insulated with R-3, ½" thick insulation	1.14	2.27
½" PEX insulated with R-3, ½" thick insulation	1.16	2.32
¾" PEX insulated with R-3, ½" thick insulation	1.43	2.86
Vertical Pipe Orientation		
½" Copper Pipe insulated with R-3, ½" thick insulation	0.63	1.26
¾" Copper Pipe insulated with R-3, ½" thick insulation	0.82	1.63
½" PEX insulated with R-3, ½" thick insulation	0.85	1.70
¾" PEX insulated with R-3, ½" thick insulation	1.1	2.20
Unknown		
R-3, ½" thick insulation for ½" pipes – pipe type and	0.9	1.79

[847] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

[848] Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 78%

	ΔTherm Savings per Foot of Insulation (Therms/ft)	
Measure Configuration	Kit Distribution (ISR = 50%)	All Other Programs (ISR = 100%)
configuration unknown (average of vertical and horizontal configurations for ½"pipe)		
R-3, ½" thick insulation for ¾" pipes – pipe type and configuration unknown (average of vertical and horizontal configurations for ¾"pipe)	1.12	2.24
Unknown pipe type (straight average) and configuration (average of vertical and horizontal configurations for all pipes) insulated with R-3, ½" thick insulation	1.01	2.01

5.4.2 Gas Water Heater

DESCRIPTION

This measure characterizes:

a) Time of sale or new construction:

The purchase and installation of a new efficient gas-fired water heater, in place of a Federal Standard unit in a residential setting. Savings are provided for power-vented, condensing storage, and whole-house tankless units meeting specific Uniform Energy Factor (UEF) criteria.

b) Early replacement:

The early removal of an existing functioning natural gas water heater from service, prior to its natural end of life, and replacement with a new high efficiency unit. Savings are calculated between existing unit and efficient unit consumption during the remaining life of the existing unit, and between new baseline unit and efficient unit consumption for the remainder of the measure life.

This measure was developed to be applicable to the following program types: TOS, NC, EREP.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, the installed equipment must be a residential gas-fired storage water heater or Instantaneous (tankless) water heater meeting ENERGY STAR[849] criteria. [850]

Water Heater Type	Water Heater Tank Volume (gallons)	Draw Pattern	Minimum Uniform Energy Factor
Gas Storage	≤ 55	Medium	≥ 0.81
		High	≥ 0.86
	> 55	All	≥ 0.86
Gas Instantaneous	All	All	≥ 0.95

DEFINITION OF BASELINE EQUIPMENT

New Construction: The baseline equipment is assumed to be a new, gas-fired storage residential water heater meeting minimum Federal efficiency standards as provided below.

Time of Sale: The baseline equipment is assumed to be the same water heater type as the unit being replaced, if unknown assume a new, gas-fired storage residential water heater meeting minimum Federal efficiency standards as provided below.

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[851]
Residential Gas Storage Water Heaters ≤75,000 Btu/h	≤55 gallon tanks	Very small	UEF = 0.3456 – (0.0020 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5982 – (0.0019 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6483 – (0.0017 * Rated Storage Volume in Gallons)
		High	UEF = 0.6920 – (0.0013 * Rated Storage Volume in Gallons)
	>55 gallon and ≤100 gallon	Very small	UEF = 0.6470 – (0.0006 * Rated Storage Volume in Gallons)
		Low	UEF = 0.7689 – (0.0005 * Rated Storage Volume in Gallons)

[849] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[850] ENERGY STAR Product Specification for Residential Water Heaters, Version 5.0, effective April 18, 2023.
[851] DOE Standard 10 CFR 430, Residential-Duty and Commercial Federal Standard are from DOE Standard 10 CFR 431. Minimum Federal standard as of 4/16/2015, confirmed no changes as of 4/28/2024;
https://www.ecfr.gov/cgi-bin/text-idx?SID=80dfa785ea350ebeee184bb0ae03e7f0&mc=true&node=se10.3.430_132&rgn=div8

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[851]
	tanks	Medium	UEF = 0.7897 – (0.0004 * Rated Storage Volume in Gallons)
		High	UEF = 0.8072 – (0.0003 * Rated Storage Volume in Gallons)
Residential Gas Fired Instantaneous Water Heaters	< 2 gal and >50,000 Btu/h	Very small	UEF = 0.80
		All other	UEF = 0.81

Draw patterns are based on first hour rating (gallons) for storage tanks as shown below:[852]

Storage Water Heater Draw Pattern	
Draw Pattern	**First Hour Rating (gallons)**
Very Small	≥ 0 and < 18
Low	≥ 18 and < 51
Medium	≥ 51 and < 75
High	≥ 75

The same draw pattern (very small, low, medium and high draw) should be used for both baseline and efficient units. If using a deemed approach, for storage water heaters with a storage capacity equal to or less than 55 gallons, the Federal energy factor requirement is calculated as 0.6483 – (0.0017 * storage capacity in gallons) assuming a Medium draw and 0.8072 − (0.0003 × storage capacity in gallons) assuming a High draw for greater than 55 gallon storage water heaters.

Early Replacement: The baseline is the efficiency of the existing gas water heater for the remaining useful life of the unit and the efficiency of a new gas water heater of the same type meeting minimum Federal efficiency standards for the remainder of the measure life.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 14.5 years for gas storage water heaters and 20.0 years for gas instantaneous water heaters.[853]

For early replacement: Remaining life of existing gas storge and instantaneous water heaters is assumed to be 4.8 and 6.7 years, respectively.[854]

DEEMED MEASURE COST

Time of Sale or New Construction:

The incremental capital cost for this measure is dependent on the type of water heater as listed below.[855]

Early Replacement: The full installed cost is provided in the table below. The assumed deferred cost (after 4 years) of replacing existing equipment with a new baseline unit is also provided in the table below. This cost should be discounted to present value using the nominal discount rate.

[852] Definitions provided in 10 CFR 430, Subpart B, Appendix E, Section 5.4.1
[853] Supporting document for Energy Conservation Program: Energy Conservation Standards for Consumer Water Heaters. 2023-07-21 Consumer Water Heater Life-Cycle Cost (LCC) and Payback Period Results Analysis (NOPR), EERE-2017-BT-STD-0019-0061.
[854] Assumed to be one third of effective useful life
[855] Supporting document for Energy Conservation Program: Energy Conservation Standards for Consumer Water Heaters. 2023-07-21 Consumer Water Heater Life-Cycle Cost (LCC) and Payback Period Results Analysis (NOPR), EERE-2017-BT-STD-0019-0061.

Water Heater Type	Water Heater Tank Volume (gallons)	Draw Pattern	Incremental Cost	Full Install Cost	Deferred Baseline Replacement Cost[856]
Gas Storage	≤ 55	Medium	$230	$1,968	$1,902
		High	$215	$2,051	$2,009
	> 55	All	$215	$2,051	$2,009
Gas Instantaneous	All	All	$293	$1,954	$1,818

FOSSIL FUEL SAVINGS

Time of Sale or New Construction:

$$\Delta Therms = (1/ UEF_{BASE} - 1/UEF_{EFFICIENT}) * (GPD * Household * 365.25 * \gamma Water * (T_{OUT} – T_{IN}) * 1.0)/100,000$$

Early replacement:[857]

ΔTherms for remaining life of existing unit (1st 3.7 years for gas storage unit and 1st 6.7 years for gas tankless unit):

$$= (1/ UEF_{EXISTING} - 1/UEF_{EFFICIENT}) * (GPD * Household * 365.25 * \gamma Water * (T_{OUT} – T_{IN}) * 1.0)/100,000$$

ΔTherms for remaining measure life (next 7.3 years for gas storage unit and next 13.3 years for gas tankless unit):

$$= (1/ UEF_{BASE} - 1/UEF_{EFFICIENT}) * (GPD * Household * 365.25 * \gamma Water * (T_{OUT} – T_{IN}) * 1.0)/100,000$$

Where:

UEF_Baseline = Uniform Energy Factor rating of standard storage water heater according to federal standards[858] provided in table in baseline section and using the same draw pattern as the efficient equipment. For a deemed approach:

= For gas storage water heaters ≤55 gallons: 0.6483 – (0.0017 * storage capacity in

[856] The implied baseline cost from the incremental and full cost is calculated and then inflated applying inflation rate of 2.28% for 4 years.

[857] The two equations are provided to show how savings are determined during the initial phase of the measure (existing to efficient) and the remaining phase (new baseline to efficient). In practice, the screening tools used may either require a First Year savings (using the first equation) and then a "number of years to adjustment" and "savings adjustment" input which would be the (new base to efficient savings)/(existing to efficient savings).

[858] Minimum Federal standard as of 4/16/2015, Confirmed no changes as of 4/28/2023.

gallons)

= For gas storage water heaters >55 gallons: 0.8072 − (0.0003 × storage capacity in gallons)

= If tank size is unknown, assume 0.563 for a gas storage water heater with a 50-gallon storage capacity

UEF_Efficient = Uniform Energy Factor Rating for efficient equipment

= Actual. If unknown[859] assume:

Unit Type	Unit Capacity	Draw Pattern	Uniform Energy Factor
Gas Storage	≤ 55 gallons	Medium	0.81
		High	0.86
	> 55 gallons	All	0.86
Gas Tankless	All	All	0.95

UEF_Existing = Uniform Energy Factor rating for existing equipment

= Use actual UEF rating where it is possible to measure or reasonably estimate.

= if unknown assume 0.52 [860]

GPD = Gallons Per Day of hot water use per person

= 45.5 gallons hot water per day per household/2.59 people per household.[861]

= 17.6

Household = Average number of people per household

Household Unit Type	Household[862]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[863]
Custom	Actual Occupancy or Number of Bedrooms[864]		

Use Multifamily if: Building meets utility's definition for multifamily

365.25 = Days per year, on average

γWater = Specific Weight of water

= 8.33 pounds per gallon

T_{OUT} = Tank temperature

= 125°F

[859] ENERGY STAR Product Specification for Residential Water Heaters, Version 5.0, effective April 23, 2023.
[860] Based on DCEO Efficient Living Program Data for a sample size of 157 gas water heaters.
[861] Deoreo, B., and P. Mayer. Residential End Uses of Water Study Update. Forthcoming. ©2015 Water Research Foundation. Reprinted With Permission.
[862] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.
[863] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.
[864] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

T_{IN} = Incoming water temperature from well or municipal system

= 50.7°F [865]

1.0 = Heat Capacity of water (1 Btu/lb*°F)

For example, a 40 gallon condensing gas storage water heater, with a uniform energy factor of 0.86 in a single family IQ house:

ΔTherms = (1/0.58 - 1/0.86) * (17.6 * 2.76 * 365.25* 8.33 * (125 – 50.7) * 1) / 100,000

= 61.6 therms

[865] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

5.4.3 Heat Pump Water Heaters

DESCRIPTION

A heat pump water heater provides domestic water heating by moving heat between indoor air (conditioned or unconditioned) and a storage water tank.

This measure characterizes:

a) New Construction:
- The installation of a domestic heat pump water heater meeting ENERGY STAR[866] efficiency standards in a new home.
- Note that the baseline in this case should be determined via EM&V and the algorithms are provided to allow savings to be calculated from any baseline condition.

b) Time of Sale:
- The installation of a domestic heat pump water heater in place of a standard electric or fossil fuel-fired water heater in a home.
- Note that the baseline in this case is an equivalent replacement system to that which exists currently in the home. Where unknown, the baseline can be assumed to be a 50 gallon electric storage water heater with medium draw pattern.

c) Early Replacement
- The early removal of a functioning fossil-fuel fired water heater from service, prior to its natural end of life, and replacement with a new domestic heat pump water heater.
- Note that the baseline in this case is the existing equipment being replaced. Savings are calculated between the existing unit and efficient unit consumption during the remaining life of the existing unit, and between a new equivalent replacement system to that which exists currently in the home and efficient unit consumption for the remainder of the measure life.

Savings are presented dependent on the heating system installed in the home, presence of cooling, and presence of dehumidification due to the impact of the heat pump water heater on the heating cooling and dehumidification loads.

This measure was developed to be applicable to the following program types: TOS, NC, ER.
If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be an ENERGY STAR Heat Pump domestic water heater.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a new water heater meeting federal minimum efficiency standards, dependent on the storage volume (in gallons) of the water heater.

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[867]
Residential Electric Storage Water Heaters ≤ 75,000 Btu/h	≤55 gallon tanks	Very small	UEF = 0.8808 – (0.0008 * Rated Storage Volume in Gallons)
		Low	UEF = 0.9254 – (0.0003 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.9307 – (0.0002 * Rated Storage Volume in Gallons)
		High	UEF = 0.9349 – (0.0001 * Rated Storage Volume in Gallons)
	>55 gallon and ≤120	Very small	UEF = 1.9236 – (0.0011 * Rated Storage Volume in Gallons)
		Low	UEF = 2.0440 – (0.0011 * Rated Storage Volume in Gallons)

[866] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[867] All Residential sized Federal Standards are from DOE Standard 10 CFR 430, Residential-Duty and Commercial Federal Standard are from DOE Standard 10 CFR 431.

Equipment Type	Sub Category	Draw Pattern	Federal Standard – Uniform Energy Factor[867]
	gallon tanks [868]	Medium	UEF = 2.1171 – (0.0011 * Rated Storage Volume in Gallons)
		High	UEF = 2.2418 – (0.0011 * Rated Storage Volume in Gallons)
Residential Electric Instantaneous Water Heaters	≤12kW and ≤2 gal	All other	UEF = 0.91
		High	UEF = 0.92
Residential Gas Storage Water Heaters ≤75,000 Btu/h	≤55 gallon tanks	Very small	UEF = 0.3456 – (0.0020 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5982 – (0.0019 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6483 – (0.0017 * Rated Storage Volume in Gallons)
		High	UEF = 0.6920 – (0.0013 * Rated Storage Volume in Gallons)
	>55 gallon and ≤100 gallon tanks	Very small	UEF = 0.6470 – (0.0006 * Rated Storage Volume in Gallons)
		Low	UEF = 0.7689 – (0.0005 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.7897 – (0.0004 * Rated Storage Volume in Gallons)
		High	UEF = 0.8072 – (0.0003 * Rated Storage Volume in Gallons)
Residential Gas Fired Instantaneous Water Heaters	< 2 gal and >50,000 Btu/h	Very small	UEF = 0.80
		All other	UEF = 0.81
Residential Oil Storage Water Heater	≤50 gallon tanks	Very small	UEF = 0.2509 – (0.0012 * Rated Storage Volume in Gallons)
		Low	UEF = 0.5330 – (0.0016 * Rated Storage Volume in Gallons)
		Medium	UEF = 0.6087 – (0.0016 * Rated Storage Volume in Gallons)
		High	UEF = 0.6815 – (0.0014 * Rated Storage Volume in Gallons)

The same draw pattern (very small, low, medium and high draw) should be used for both baseline and efficient units. If using a deemed approach, for units ≤55 gallons – baseline is assumed to be a resistance storage unit with efficiency: 0.9307 – (0.0002 * rated volume in gallons) assuming medium draw.

For units >55 gallons – assume a 50 gallon resistance tank baseline;[869] i.e., 0.9299 UEF assuming high draw .

If unknown, assume a 50 gallon resistance tank baseline, at medium draw, therefore 0.9207 UEF. [870]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years.[871]

DEEMED MEASURE COST

For Time of Sale or New Construction the incremental installation cost (including labor) should be used. Default equipment and incremental installation costs are provided below.

For retrofit costs, the actual full installation cost should be used (default provided below if unknown).

[868] It is assumed that tanks <75,000Btu/h and >55 gallons will not be eligible measures due to the high baseline.
[869] A 50 gallon volume tank for the baseline is assumed to capture market practice of using larger heat pump water heaters to achieve greater efficiency of the heat pump cycle and preventing the unit from going in electric resistance mode.
[870] About 90% of all water heaters are installed in a replace-on-burnout situation and installers strongly prefer like-for-like equipment replacements in these situations, meaning that fuel switching is unlikely in TOS situations. As stated in Opinion Dynamics Ameren Illinois' Market Effects Pilot – Heat Pump Hot Water Market Characterization Report, March 4, 2021.
[871] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.

Capacity	Voltage	Baseline Installed Cost[872]	Efficient Installed Cost[873]	Incremental Installed Cost
≤55 gallons	120V	$882[874]	$2,416	$1,534
	240V	$882	$2,072	$1,190
>55 gallons	120V	$882	$3,884	$3,002
	240V	$882	$2,577	$1,695

For reference, as needed, additional installation costs are provided below. The total of any additional electrification costs should be divided across all applicable measures weighted by total MMBtu savings.

Additional Installation Item	Number of Instances	Average Cost[875]
Upgrade Electric Panel	3	$2,523
New Circuit	4	$338
Air Flow	5	$425
Thermostatic Mixing Valve	2	$899

LOADSHAPE

Loadshape R18 - Residential Heat Pump Water Heater

COINCIDENCE FACTOR

The summer Peak Coincidence Factor is assumed to be 12%.[876]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY AND FOSSIL FUEL SAVINGS

Non fuel switch measures:

$$\Delta kWh = (((1/UEF_{BASE} - 1/UEF_{HPWHEFFICIENT}) * GPD * Household * 365.25 * \gamma Water * (T_{OUT} - T_{IN}) * 1.0) / 3412) + CoolingImpact - ElecHeatImpact + Deh_Reduction$$

[872] Baseline ERWH equipment costs: Energy Solutions (2024). Heat Pump Water Heaters in the Northeast and Mid-Atlantic: Costs and Market Trends. Prepared for: Northeast States for Coordinated Air Use Management (NESCAUM) and The Ozone Transport Commission (OTC). Installation labor cost from same study suggests $308, for a total of $882. Additionally, a review of 18 baseline ERWH models (5 different manufacturers; sizes ranging from 30-50 gallons) listed with online retailers (Home Depot, Lowes, Menards, and Ferguson Supply) available in IL established an average equipment cost of $575.

[873] Efficient Equipment costs are based on measure cost information from PY2024-YTD2025 Ameren Illinois Retail Products Initiative data for: 19 120V HPWH and 225 240V HPWH sales. In the vast majority of cases, the only cost difference between the installation of a HPWH and an ERWH is the need to install a drain line to redirect condensate from the HPWH. This additional installation cost is assumed to be $100 for HPWH installations.

[874] As there are no 120V electric resistance water heaters (ERWHs) on the market, 240V ERWHs serve as the baseline product for comparison with 120V HPWHs

[875] Cost information is derived from 198 HPWH installations through the Ameren Illinois Income Qualified Initiative from PY2023-YTD2025. Note panel upgrade cost is consistent with Energy Solutions (2024). Heat Pump Water Heaters in the Northeast and Mid-Atlantic: Costs and Market Trends. Prepared for: Northeast States for Coordinated Air Use Management (NESCAUM) and The Ozone Transport Commission (OTC) – which estimated an average cost of $2,275 for a panel upgrade.

[876] Calculated from Figure 8 "Combined six-unit summer weekday average electrical demand" in FEMP study; 'Field Testing of Pre-Production Prototype Residential Heat Pump Water Heaters' as (average kW usage during peak period * hours in peak period) / [(annual kWh savings / FLH) * hours in peak period] = (0.1 kW * 5 hours) / [(2100 kWh (default assumptions) / 2533 hours) * 5 hours] = 0.12

CoolingImpact[877] = Cooling savings from conversion of heat in home to water heat

=((((GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) – ((1/ $UEF_{HPWHEFFICIENT}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412)) * LF * 27%) / COP_{COOL}) * LM

ElecHeatImpact = Electric heating cost from conversion of heat in home to water heat (dependent on heating fuel)

= (((((GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) – ((1/ $UEF_{HPWHEFFICIENT}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412)) * LF * 37%) / COP_{HEAT}) * (1 - %FossilHeat)

Deh_Reduction = Savings resulting from reduced dehumidification (provided in table in variable list below)

$\Delta Therms_{HeatImpact}$ = Fossil heating cost from conversion of heat in home to water heat for homes with Natural Gas heat

= - (((((GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) – (GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) / $UEF_{HPWHEFFICIENT}$)) * LF * 37% * 0.03412) / ηHeat) * %FossilHeat

Fuel switch measures:

Fuel switch measures must produce positive total lifecycle energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

SiteEnergySavings (MMBTUs) = [FossilWHReplaced] – [ElectricWHAdded] + [HVACImpacts]

FossilWHReplaced = Fossil fuel consumption of replaced fossil fuel water heater

= (1/$UEF_{GASBASE}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0)/1,000,000

ElectricWHAdded = Added electric consumption of heat pump water heater

= (1/ $UEF_{HPWHEFFICIENT}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) /1,000,000

HVACImpacts [counted as non-fuel switch savings] = Heating and cooling impact of heat pump water heater

= [CoolingImpact * 3,412/1,000,000] – [ElecHeatImpact * 3,412/1,000,000] + [Deh_reduction * 3,412/1,000,000] – [$\Delta Therms_{HeatImpact}$ * 1/10]

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

[877] This algorithm calculates the heat removed from the air by subtracting the HPWH electric consumption from the total water heating energy delivered. This is then adjusted to account for location of the HP unit and the coincidence of the waste heat with cooling requirements, the efficiency of the central cooling and latent cooling demands.

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Note for Early Replacement measures, the efficiency terms of the existing water heater should be used for the remaining useful life of the existing equipment and the efficiency terms for a new baseline unit should be used for the remaining years of the measure. See assumptions below.

Where:

UEF_{BASE} = Uniform Energy Factor (efficiency) of standard water heater according to federal standards provided in table in baseline section and using the same draw pattern as the efficient equipment. For a deemed approach assume electric water heater:

For <=55 gallons: 0.9307 – (0.0002 * rated volume in gallons)

For >55 gallons: Use 0.9299 [878]

= If unknown volume, use 0.9207 [879]

$UEF_{HPWHEFFICIENT}$ = Uniform Energy Factor (efficiency) of Heat Pump water heater

= Actual

GPD = Gallons Per Day of hot water use per person

= 45.5 gallons hot water per day per household/2.59 people per household [880]

= 17.6

Household = Average number of people per household

Household Unit Type	Household[881]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[882]
Custom	Actual Occupancy or Number of Bedrooms[883]		

[878] Assuming a 50 gallon tank baseline at High Draw due to the accommodate the higher gallon range. 50 gallon is the most common size for HPWHs.
[879] Assuming a 50 gallon tank baseline at Medium Draw.
[880] Deoreo, B., and P. Mayer. Residential End Uses of Water Study Update. Forthcoming. ©2015 Water Research Foundation. Reprinted With Permission.
[881] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.
[882] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.
[883] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

Use Multifamily if: Building meets utility's definition for multifamily

365.25 = Days per year

γWater = Specific weight of water

= 8.33 pounds per gallon

T_{OUT} = Tank temperature

= 125°F

T_{IN} = Incoming water temperature from well or municiple system

= 50.7°F [884]

1.0 = Heat Capacity of water (1 Btu/lb*°F)

3412 = Conversion from Btu to kWh

CoolingImpact[885] = Cooling savings from conversion of heat in home to water heat

$$=(((((GPD * Household * 365.25 * \gamma Water * (T_{OUT} - T_{IN}) * 1.0) / 3412) -$$

$$((1/ UEF_{HPWHEFFICIENT} * GPD * Household * 365.25 * \gamma Water * (T_{OUT} - T_{IN}) * 1.0) / 3412)) * LF * 27\%) / COP_{COOL}) * LM$$

Where:

LF = Location Factor

= 1.0 for HPWH installation in a conditioned space

= 0.22 for HPWH installation in an unknown location[886]

= 0.0 for installation in an unconditioned space

27% = Portion of heat removed from surrounding air that results in cooling savings[887]

COP_{COOL} = COP of central air conditioning

= Assume 2.8 if central AC or unknown and 3.0 if heat pump [888]

LM = Latent multiplier to account for latent cooling demand

= 1.33 [889]

[884] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[885] This algorithm calculates the heat removed from the air by subtracting the HPWH electric consumption from the total water heating energy delivered. This is then adjusted to account for location of the HP unit and the coincidence of the waste heat with cooling requirements, the efficiency of the central cooling and latent cooling demands.

[886] West Hills Energy and Computing (2019) found 78% of HPWHs "are installed in basements that are not intentionally heated."

[887] REMRate determined percentage (27%) of lighting savings that result in reduced cooling loads (lighting is used as a proxy for hot water heating since load shapes suggest their seasonal usage patterns are similar).

[888] To reduce complexity of the measure and since this relates to a small waste heat impact, instead of assuming actual existing unit HVAC efficiency and a mid-life adjustment to account for future replacement efficiency, the code minimum baseline should be applied. Starting from federal baseline of SEER2 13.4 central AC unit, converted to 11.4 EER using algorithm (-0.02 * $SEER^2$) + (1.12 * SEER) (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = (EER2 * 0.85)/3.412 = 2.8COP. Same calculation starting with federal baseline of SEER2 14.3 heat pump results in COP of 3.0.

[889] A sensible heat ratio (SHR) of 0.75 corresponds to a latent multiplier of 4/3 or 1.33. SHR of 0.75 for typical split system from page 10 of "Controlling Indoor Humidity Using Variable-Speed Compressors and Blowers" by M. A. Andrade and C. W. Bullard, 1999.

ElecHeatImpact = Heating cost from conversion of heat in home to water heat (dependent on heating fuel)

= (((((GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) –

((1/ $UEF_{HPWHEFFICIENT}$* GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412)) * LF * 37%) / COP_{HEAT}) * (1 - %FossilHeat)

Where:

37% = Portion of heat removed from surrounding air that results in increased heating load[890]

COP_{HEAT} = COP of electric heating system

= actual. If not available use:[891]

System Type	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Heat Pump	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	1.00
Unknown electric[892]	N/A	1.35

Deh_Reduction = Savings resulting from reduced dehumidification

= values based on table below[893]

Dehumidifcation Status	Deh_Reduction (kWh)
If Dehumidifer is in use	359
If unknown	72

$\Delta Therms_{HeatImpact}$ = Heating cost from conversion of heat in home to water heat for homes with Natural Gas heat [894]

[890] The operation of a HPWH causes both sensible and latent heat transfer with the surrounding air (and water vapor). Only the sensible heat transfer increases the heating load. The portion of the energy transferred from the surrounding air is based on the average result from REMRate modeling of several different configurations and IL locations of homes (49%). The portion of that which is sensible heat further depends on the typical sensible heat ratio of 0.75 (see previous note) the resulting portion of sensible heat transferred from the surrounding air is: 49% * 0.75 = 37%.

[891] To reduce complexity of the measure and since this relates to a small waste heat impact, instead of assuming actual existing unit HVAC efficiency and a mid-life adjustment to account for future replacement efficiency, the code minimum baseline should be applied. Note efficiency includes duct losses. Defaults provided assume 15% duct loss for heat pumps.

[892] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[893] West Hills Energy and Computing (2019) found that 20% of homes had dehumidifiers in use and in interviews with homeowners found the following reductions in dehumidifier usage: 46% reported "1 month or more reduction", 32% reported "3 months or more reduction", and 15% reported removal of a dehumidifier. kWh savings assumptions are based on an average of: Federal Standard, ENERGY STAR, and ENERGY STAR Most Efficient annual energy usage. See HPWH_CalculationSheet.xlsx for calculations.

[894] This is the additional energy consumption required to replace the heat removed from the home during the heating season by the heat pump water heater. kWh_heating (electric resistance) is that additional heating energy for a home with electric resistance heat (COP 1.0). This formula converts the additional heating kWh for an electric resistance home to the MMBtu required in a Natural Gas heated home, applying the relative efficiencies.

= - (((((GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) – (GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) / $UEF_{HPWHEFFICIENT}$)) * LF * 37% * 0.03412) / ηHeat) * %FossilHeat

Where:

0.03412 = conversion factor (therms per kWh)

ηHeat = Efficiency of heating system

= Assume 68% for gas furnace or unknown, 71% for oil furnace, 84% for gas boiler and 86% for oil boiler. [895]

%FossilHeat = Factor dependent on heating fuel:

= 100 % for fossil fuel heating

= 0 % for Electric Resistance or Heat Pump

= If unknown[896], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[897]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

[895] To reduce complexity of the measure and since this relates to a small waste heat impact, instead of assuming actual existing unit HVAC efficiency and a mid-life adjustment to account for future replacement efficiency, the code minimum baseline should be applied. Note efficiency includes duct losses. Defaults provided assume 15% duct loss for heat pumps.

[896] All values except for People's Gas and Northshore Gas are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential baseline Study Results", Oct 31 2024. People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[897] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

For example, a 2.0 UEF heat pump water heater, in a conditioned space in a single family IQ home with gas furnace space heat (68% system efficiency) and central air conditioning (SEER 10.5) in in Belleville and dehumidifier usage is unknown:

ΔkWh = [(1 / 0.9207 – 1 / 2.0) * 17.6 * 2.76 * 365.25* 8.33 * (125 – 50.7) * 1.0] / 3412 + 162.4 – 0 + 72
= 2121 kWh

ΔTherms = -(((((17.6 * 2.76 * 365.25* 8.33 * (125 – 50.7) * 1.0) / 3412) – (17.6 * 2.56 * 365.25* 8.33 * (125 – 50.7) * 1.0 / 3412 / 2.0)) * 1 * 0.37 * 0.03412) / 0.68) * 1
= - 32.0 therms

Fuel Switch example, a 2.0 UEF heat pump water heater, in a conditioned space in a single family IQ home with gas furnace space heat (68% system efficiency) and central air conditioning (SEER 10.5) in in Belleville and dehumidifier usage is unknown, in place of a baseline 0.64UEF gas water heater:

SiteEnergySavings (MMBTUs) = [FossilWHReplaced] – [ElectricWHAdded] + [HVACImpacts]

FossilWHReplaced = $(1/UEF_{GASBASE} * GPD * Household * 365.25 * \gamma Water * (T_{OUT} – T_{IN}) * 1.0)/1{,}000{,}000$
= (1/0.64 * 17.6 * 2.76 * 365.25* 8.33 * (125 – 50.7) * 1.0)/1,000,000
= 17.2 MMBtu

ElectricWHAdded = $(1/ UEF_{HPWHEFFICIENT} * GPD * Household * 365.25 * \gamma Water * (T_{OUT} – T_{IN}) * 1.0) /1{,}000{,}000$
= (1/2.0 * 17.6 * 2.76 * 365.25* 8.33 * (125 – 50.7) * 1.0)/1,000,000
= 5.5 MMBtu

HVACImpacts = [CoolingImpact * 3,412/1,000,000] – [ElecHeatImpact * 3,412/1,000,000] + [Deh_reduction * 3,412/1,000,000] – [$\Delta Therms_{HeatImpact}$ * 1/10]
= (188.9 * 3412/1000000) – (0 * 3412/1000000) + (72 * 3412/1000000) – (27.7 * 1/10)
= -1.88 MMBtu

SiteEnergySavings (MMBTUs) = 17.2 – 5.5 + (-1.88)
= 9.82 MMBtu

If supported by an electric utility: ΔkWh = ΔSiteEnergySavings * 1,000,000 / 3,412
= 9.82 * 1,000,000/3,412
= 2,878 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh / Hours * CF

Where:

ΔkWh = Electric savings (or increase) of measure

= For non-fuel switch measures, use ΔkWh as provided in Electric Energy Savings section above, for fuel-switch measures use the ΔkWh as provided in the Cost Effectiveness Screening and Load Reduction Forecasting when Fuel Switching section below

Hours = Full load hours of water heater

= 2533 [898]

CF = Summer Peak Coincidence Factor for measure

= 0.12 [899]

For example, a 2.0 UEF heat pump water heater, in a conditioned space in a single family IQ home with gas space heat and central air conditioning in Belleville and dehumidifier usage is unknown:

kW = 2121 / 2533 * 0.12

= 0.100kW

FOSSIL FUEL SAVINGS

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

COST EFFECTIVENESS SCREENING AND LOAD REDUCTION FORECASTING WHEN FUEL SWITCHING

This measure can involve fuel switching from fossil fuel to electric.

For the purposes of forecasting load reductions due to fuel switch projects per Section 16-111.5B, changes in site energy use at the customer's meter (using ΔkWh algorithm below), customer switching estimates, NTG, and any other adjustment factors deemed appropriate, should be used.

The inputs to cost effectiveness screening should reflect the actual impacts on the electric and fuel consumption at the customer meter and, for fuel switching measures, should therefore reflect the decrease in one fuel and increase in another, as opposed to the single savings value calculated in the "Electric and Fossil Fuel Energy Savings" section above. Therefore in addition to the calculation of savings claimed, the following values should be used to assess the cost effectiveness of the measure.

ΔTherms = [Gas Water Heating Consumption Replaced] – [$\Delta Therms_{HeatImpact}$]

= [(1/$UEF_{GASBASE}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0)/100,000] – [((((GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) – (GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) / $UEF_{HPWHEFFICIENT}$)) * LF * 37% * 0.03412) / ηHeat) * %FossilHeat]

ΔkWh = - [Electric Water Heating Consumption Added] + [CoolingImpact] – [ElecHeatImpact] + [Deh-Reduction]

= - (1/ $UEF_{HPWHEFFICIENT}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) /3,412] +

[898] Full load hours assumption based on Efficiency Vermont analysis of Itron eShapes.

[899] Calculated from Figure 8 "Combined six-unit summer weekday average electrical demand" in FEMP study; 'Field Testing of Pre-Production Prototype Residential Heat Pump Water Heaters' as (average kW usage during peak period * hours in peak period) / [(annual kWh savings / FLH) * hours in peak period] = (0.1 kW * 5 hours) / [(2100 kWh / 2533 hours) * 5 hours] = 0.12

[(((GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) – ((1/ $UEF_{HPWHEFFICIENT}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412)) * LF * 27%) / COP_{COOL}) * LM] – [(((GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412) – ((1/ $UEF_{HPWHEFFICIENT}$ * GPD * Household * 365.25 * γWater * (T_{OUT} – T_{IN}) * 1.0) / 3412)) * LF * 37%) / COP_{HEAT}) * (1 - %FossilHeat)] + [Deh-Reduction]

MEASURE CODE: RS-HWE-HPWH-V15-260101

REVIEW DEADLINE: 1/1/2029

5.4.4 Low Flow Faucet Aerators

DESCRIPTION

This measure relates to the installation of a low flow faucet aerator in a household kitchen or bath faucet fixture.

This measure may be used for units provided through Efficiency Kits however the in-service rate for such measures should be derived through evaluation results specifically for this implementation methodology.

This measure was developed to be applicable to the following program types: TOS, NC, RF, DI, KITS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a low flow faucet aerator, for bathrooms rated at 1.5 gallons per minute (GPM) or less, or for kitchens rated at 2.2 GPM or less. Savings are calculated on an average savings per faucet fixture basis.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is assumed to be a standard bathroom faucet aerator rated at 2.2 GPM or greater, or a standard kitchen faucet aerator rated at 2.2 GPM or greater.

Average measured flow rates are used in the algorithm and are lower, reflecting the penetration of previously installed low flow fixtures (and therefore the freerider rate for this measure should be 0), use of the faucet at less than full flow, debris buildup, and lower water system pressure than fixtures are rated at.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[900]

DEEMED MEASURE COST

For time of sale or new construction the incremental cost for this measure is $3,[901] or program actual.

For faucet aerators provided through Direct Install or within Efficiency Kits, the actual program delivery costs (including labor if applicable) should be utilized. If unknown, assume $8 for Direct Install[902] and $3 for Efficiency Kits.

LOADSHAPE

Loadshape R03 - Residential Electric DHW

COINCIDENCE FACTOR

The coincidence factor for this measure is assumed to be 2.2%.[903]

[900] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.
[901] 2011, Market research average of $3.
[902] Includes assess and install labor time of $5 (20min @ $15/hr)
[903] Calculated as follows: Assume 18% aerator use takes place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.) There are 65 days in the summer peak period, so the percentage of total annual aerator use in peak period is 0.18*65/365 = 3.21%. The number of hours of recovery during peak periods is therefore assumed to be 3.21% *180 = 5.8 hours of recovery during peak period where 180 equals the average annual electric DHW recovery hours for faucet use including SF and MF homes. There are 260 hours in the peak period so the probability you will see savings during the peak period is 5.8/260 = 0.022

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Note these savings are *per* faucet retrofitted[904] (unless faucet type is unknown, then it is per household).

ΔkWh = %ElectricDHW * ((GPM_base * L_base - GPM_low * L_low) * Household * 365.25 *DF / FPH) * EPG_electric * ISR

Where:

%ElectricDHW = Percentage of DHW savings assumed to be electric

= 100 % for Electric

= 0 % for Fossil Fuel

= If unknown[905], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	19.7%	30.6%	63.3%	67.3%	31.4%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
People's Gas	2.1%	2.0%	1.7%	2.4%	2.2%
Northshore Gas	1.5%	1.8%	10.0%	2.4%	2.4%
Nicor Gas	7.6%	9.9%	14.4%	22.6%	10.0%
All DUs[906]					**29%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

GPM_base = Average flow rate, in gallons per minute, of the baseline faucet "as-used."

= If unknown assume values in table below, or custom based on metering studies,[907] or if measured during DI:

= Measured full throttle flow * 0.83 throttling factor[908]

Note, if GPM_base is based upon the deemed assumptions below, since these include

[904] This algorithm calculates the amount of energy saved per aerator by determining the fraction of water consumption savings for the upgraded fixture.

[905] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[906] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[907] Measurement should be based on actual average flow consumed over a period of time rather than a onetime spot measurement for maximum flow. Studies have shown maximum flow rates do not correspond well to average flow rate due to occupant behavior which does not always use maximum flow.

[908] 2008, Schultdt, Marc, and Debra Tachibana. Energy related Water Fixture Measurements: Securing the Baseline for Northwest Single Family Homes. 2008 ACEEE Summer Study on Energy Efficiency in Buildings. Page 1-265. www.seattle.gov/light/Conserve/Reports/paper_10.pdf

participants that had existing low flow fixtures, the freerider rate for this measure should be 0.

Faucet Type	GPM[909]
Kitchen	1.63
Bathroom	1.53
If faucet location unknown	1.58

GPM_low = Average flow rate, in gallons per minute, of the low-flow faucet aerator "as-used"

= 0.94,[910] or custom based on metering studies,[911] or if measured during DI:

= Rated full throttle flow * 0.95 throttling factor[912]

L_base = Average baseline daily length faucet use per capita for faucet of interest in minutes

= if available custom based on metering studies, if not use:

Faucet Type	L_base (min/person/day)
Kitchen	4.5[913]
Bathroom	1.6[914]
If faucet location unknown (total for household): Single-Family except mobile homes	9.0[915]
If location unknown (total for household): Multifamily and mobile homes	6.9[916]
If faucet location and building type unknown (total for household)	8.3[917]

L_low = Average retrofit daily length faucet use per capita for faucet of interest in minutes

= if available custom based on metering studies, if not use:

[909] Based on flow meter bag testing conducted from June 2013 to January 2014 by Franklin Energy. Over 300 residential sites in the Chicago area were tested.

[910] Average retrofit flow rate for kitchen and bathroom faucet aerators from sources 2, 4, 5, and 7(see source table at end of characterization). This accounts for all throttling and differences from rated flow rates. Assumes all kitchen aerators at 2.2 gpm or less and all bathroom aerators at 1.5 gpm or less. The most comprehensive available studies did not disaggregate kitchen use from bathroom use, but instead looked at total flow and length of use for all faucets. This makes it difficult to reliably separate kitchen water use from bathroom water use. It is possible that programs installing low flow aerators lower than the 2.2 gpm for kitchens and 1.5 gpm for bathrooms will see a lower overall average retrofit flow rate.

[911] Measurement should be based on actual average flow consumed over a period of time rather than a onetime spot measurement for maximum flow. Studies have shown maximum flow rates do not correspond well to average flow rate due to occupant behavior which does not always use maximum flow.

[913] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group. This study of 135 single and Multifamily homes in Michigan metered energy parameters for efficient showerhead and faucet aerators.

[914] Ibid.

[915] One kitchen faucet plus 2.83 bathroom faucets. Based on findings from a 2009 ComEd residential survey of 140 sites, provided by Cadmus.

[916] One kitchen faucet plus 1.5 bathroom faucets. Based on findings from a 2009 ComEd residential survey of 140 sites, provided by Cadmus.

[917] Unknown is based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

Faucet Type	L_low (min/person/day)
Kitchen	4.5[918]
Bathroom	1.6[919]
If faucet location unknown (total for household): Single-Family except mobile homes	9.0[920]
If faucet location unknown (total for household): Multifamily	6.9[921]
If faucet location and building type unknown (total for household)	8.3[922]

Household = Average number of people per household

Household Unit Type	Household[923]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[924]
Custom	Actual Occupancy or Number of Bedrooms[925]		

Use Multifamily if: Building meets utility's definition for multifamily

365.25 = Days in a year, on average.

DF = Drain Factor

Faucet Type	Drain Factor[926]
Kitchen	75%
Bath	90%
Unknown	79.5%

FPH = Faucets Per Household

Faucet Type	FPH
Kitchen Faucets Per Home (KFPH)	1

[918] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.
[919] Ibid.
[920] One kitchen faucet plus 2.83 bathroom faucets. Based on findings from a 2009 ComEd residential survey of 140 sites, provided by Cadmus.
[921] One kitchen faucet plus 1.5 bathroom faucets. Based on findings from a 2009 ComEd residential survey of 140 sites, provided by Cadmus.
[922] Unknown is based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.
[923] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.
[924] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.
[925] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.
[926] Because faucet usages are at times dictated by volume, only usage of the sort that would go straight down the drain will provide savings. VEIC is unaware of any metering study that has determined this specific factor and so through consensus with the Illinois Technical Advisory Group have deemed these values to be 75% for the kitchen and 90% for the bathroom. If the aerator location is unknown an average of 79.5% should be used which is based on the assumption that 70% of household water runs through the kitchen faucet and 30% through the bathroom (0.7*0.75)+(0.3*0.9)=0.795.

Faucet Type	FPH
Bathroom Faucets Per Home (BFPH): Single-Family except mobile homes	2.83[927]
Bathroom Faucets Per Home (BFPH): Multifamily and mobile homes	1.5[928]
If faucet location unknown (total for household): Single-Family except mobile homes	3.83
If faucet location unknown (total for household): Multifamily and mobile homes	2.5
If faucet location and building type unknown (total for household)	3.42[929]

EPG_electric = Energy per gallon of water used by faucet supplied by electric water heater

= (8.33 * 1.0 * (WaterTemp - SupplyTemp)) / (RE_electric * 3,412)

= (8.33 * 1.0 * (86 – 50.7)) / (0.98 * 3,412)

= 0.0879 kWh/gal (Bath), 0.1054 kWh/gal (Kitchen), 0.1004 kWh/gal (Unknown)

8.33 = Specific weight of water (lbs/gallon)

1.0 = Heat Capacity of water (btu/lb-°F)

WaterTemp = Assumed temperature of mixed water

= 86°F for Bath, 93°F for Kitchen 91°F for Unknown[930]

SupplyTemp = Assumed temperature of water entering house

= 50.7°F [931]

RE_electric = Recovery efficiency of electric water heater

= 98% [932]

3412 = Converts Btu to kWh (btu/kWh)

ISR = In service rate of faucet aerators dependant on install method as listed in table below

[927]Based on findings from a 2009 ComEd residential survey of 140 sites, provided by Cadmus.

[928] Ibid.

[929] Unknown is based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[930] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group. If the aerator location is unknown an average of 91% should be used which is based on the assumption that 70% of household water runs through the kitchen faucet and 30% through the bathroom (0.7*93)+(0.3*86)=91F.

[931] Table 4 in Chen, et. al., “Calculating Average Hot Water Mixes of Residential Plumbing Fixtures”, June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[932] Electric water heaters have recovery efficiency of 98%.

Selection	ISR
Direct Install	0.955[933]
Virtual Assessment followed by Unverified Self-Install	0.77[934,935]
Requested Efficiency Kit	0.60[936]
Distributed Efficiency Kit (Income Eligible)	0.46[937]
Community Distributed Kit	0.45[938]
Distributed School Efficiency Kit	0.505[939]

For example, a direct installed kitchen low flow faucet aerator in an individual electric DHW IQ SF home:

ΔkWh = 1.0 * (((1.63 * 4.5 – 0.94 * 4.5) * 2.76 * 365.25 *0.75) / 1) * 0.1054 * 0.93

= 230.1 kWh

For example, a direct installed bath low flow faucet aerator in a shared electric DHW non-IQ home:

ΔkWh = 1.0 * (((1.53 * 1.6 – 0.94 * 1.6) * 2.09 * 365.25 * 0.90) /1.5) * 0.0879 * 0.93

= 35.3 kWh

For example, a direct installed low flow faucet aerator in unknown faucet in an individual electric DHW IQ SF home:

ΔkWh = 1.0 * (((1.58 * 9.0 – 0.94 * 9.0) * 2.76 * 365.25 * 0.795) /3.83) * 0.1004 * 0.93

= 112.5 kWh

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) / 1{,}000{,}000 * E_{water\ total}$$

Where

[933] ComEd Energy Efficiency/ Demand Response Plan: Plan Year 2 (6/1/2009-5/31/2010) Evaluation Report: All Electric Single Family Home Energy Performance Tune-Up Program Table 3-8. Navigant, ComEd-Nicor Gas EPY4/GPY1 Multifamily Home Energy Savings Program Evaluation Report DRAFT 2013-01-28. Average from a 2023 survey of multifamily tenants who participated in a 2023 Direct Install program through Ameren Illinois. The ISR for kitchen and bathroom aerators was found to be 97.7% and 98.3%, respectively. Opinion Dynamics, "2023 AIC Multifamily Initiatives Tenant Survey Findings Memo", Ameren Illinois, Multifamily Initiatives, April 24, 2024. These sources have been averaged to arrive at an ISR of 0.955.

[934] An equal weighted average of Direct Install and Efficiency Kit ISRs. Guidehouse, *In-Service Rates for CY2020 Single Family Virtual Assessment Measures*, August 20, 2020. Interest and applicability of measures confirmed through virtual assessment. Please note, these ISRs do not apply to retail purchases by end user.

[935] An equal weighted average of Direct Install and Efficiency Kit ISRs. Interest and applicability of measures confirmed through virtual assessment. Please note, these ISRs do not apply to retail purchases by end user.

[936] A weighted ISR was found by weighting Nicor and Ameren efficiency kit program uptake and their previously found ISRs. This analysis can be found in Faucet Aerators and Showerheads Weighted Average ISR IL TRM.xlsx.

[937] Average of Guidehouse survey research for Peoples Gas, June 16, 2020 and Research from 2021 Ameren Illinois Income Qualified participant survey, available on IL SAG website: https://ilsag.s3.amazonaws.com/AIC-Income-Qualified-Initiative-Participant-Survey-Results-Memo-FINAL-2022-02-01.pdf

[938] Research from 2018 Ameren Illinois Income Qualified participant survey.

[939] Results from Home Energy Worksheets completed by student/families in 2020, 2021, and 2022 were nearly the same as values from: Opinion Dynamics and Cadmus. 2018 AIC Residential Program Annual Impact Evaluation Report. April 30, 2019. Results from implementer-administered participant survey. Home Energy Worksheets also establish the fraction of participants who indicate they "will install later" for specific measures. Follow-up research completed by Guidehouse for Nicor Gas in 2022 found that, on average, 51.3% of respondents who initially reported that they hadn't installed specific kit measures, but "planned to" subsequently had installed the measures. Combining these findings allows for an ISR that accounts for initial and one round of subsequent intallations. To maintain a conservative estimate of ISR, the remaining 48.7% are presumed uninstalled. See: EESchoolKitSubsequentInstall_HEW.xlsx for data and calculations.

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

= 5,010[940]

For example, a direct installed kitchen low flow aerator in a single family IQ home

ΔWater (gallons) = (((1.63 * 4.5 – 0.94 * 4.5) * 2.76 * 365.25 *0.75) / 1) * 0.93

= 2,183 gallons

ΔkWh_{water} = 2,183/1,000,000 * 5,010

=10.9 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh / Hours * CF

Where:

ΔkWh = calculated value above. Note do not include the secondary savings in this calculation.

Hours = Annual electric DHW recovery hours for faucet use per faucet

= ((GPM_base * L_base) * Household/FPH * 365.25 * DF) * 0.567[941] / GPH

Building Type	Faucet location	Calculation	Hours per faucet
Single Family IQ	Kitchen	((1.63 * 4.5) * 2.76/1 * 365.25 * 0.75) * 0.567 / 26.1	120
	Bathroom	((1.53 * 1.6) * 2.76/2.83 * 365.25 * 0.9) * 0.567 / 26.1	17
	Unknown	((1.58* 9.0) * 2.76/3.83 * 365.25 * 0.795) * 0.567 / 26.1	65
Single Family Non-IQ	Kitchen	((1.63 * 4.5) * 2.62/1 * 365.25 * 0.75) * 0.567 / 26.1	114
	Bathroom	((1.53 * 1.6) * 2.62/2.83 * 365.25 * 0.9) * 0.567 / 26.1	16
	Unknown	((1.58* 9.0) * 2.62/3.83 * 365.25 * 0.795) * 0.567 / 26.1	61
Multifamily IQ	Kitchen	((1.63 * 4.5) * 2.3/1 * 365.25 * 0.75) * 0.567 / 26.1	100
	Bathroom	((1.53* 1.6) * 2.3/1.5 * 365.25 * 0.9) * 0.567 / 26.1	27
	Unknown	((1.58 * 6.9) * 2.3/2.5 * 365.25 * 0.795) * 0.567 / 26.1	63
Multifamily Non-IQ	Kitchen	((1.63 * 4.5) * 2.09/1 * 365.25 * 0.75) * 0.567 / 26.1	91
	Bathroom	((1.53* 1.6) * 2.09/1.5 * 365.25 * 0.9) * 0.567 / 26.1	24
	Unknown	((1.58 * 6.9) * 2.09/2.5 * 365.25 * 0.795) * 0.567 / 26.1	57

GPH = Gallons per hour recovery of electric water heater calculated for 69.3°F temp rise (120-50.7), 98% recovery efficiency, and typical 4.5kW electric resistance storage tank.

= 26.1

CF = Coincidence Factor for electric load reduction

= 0.022[942]

[940] This factor includes 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

[941] 56.7% is the proportion of hot 120F water mixed with 50.7F supply water to give 90F mixed faucet water.

[942] Calculated as follows: Assume 18% aerator use takes place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.) There are 65 days in the summer peak period, so the percentage of total annual aerator use in peak period is 0.18*65/365 = 3.21%. The number of hours of recovery during peak periods is

For example, a direct installed kitchen low flow faucet aerator in a single family electric DHW IQ home:

ΔkW =230.1/120 * 0.022

= 0.042 kW

FOSSIL FUEL SAVINGS

ΔTherms = %FossilDHW * ((GPM_base * L_base - GPM_low * L_low) * Household * 365.25 *DF / FPH) * EPG_gas * ISR

Where:

%FossilDHW = Percentage of DHW savings assumed to be fossil fuel

= 100 % for Fossil Fuel

= 0 % for Electric

= If unknown[943], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs					**71%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

EPG_gas = Energy per gallon of Hot water supplied by gas

= (8.33 * 1.0 * (WaterTemp - SupplyTemp)) / (RE_gas * 100,000)

= 0.0038 Therm/gal for SF homes (Bath), 0.0045 Therm/gal for SF homes (Kitchen), 0.0043 Therm/gal for SF homes (Unknown)

= 0.0044 Therm/gal for MF homes (Bath), 0.0053 Therm/gal for MF homes (Kitchen), 0.0050 Therm/gal for MF homes (Unknown)

RE_gas = Recovery efficiency of gas water heater

= 78% For individual water heater[944]

therefore assumed to be 3.21% *180 = 5.8 hours of recovery during peak period where 180 equals the average annual electric DHW recovery hours for faucet use including SF and MF homes. There are 260 hours in the peak period so the probability you will see savings during the peak period is 5.8/260 = 0.022

[943] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[944] DOE Final Rule discusses Recovery Efficiency with an average around 0.76 for Gas Fired Storage Water heaters and 0.78 for standard efficiency gas fired tankless water heaters up to 0.95 for the highest efficiency gas fired condensing tankless water heaters. These numbers represent the range of new units however, not the range of existing units in stock. Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 78%.

= 67% For shared water heater[945]

If unknown, use individual water heater value for single family, use shared water heater value for multifamily. Use multifamily if building meets utility's definition for multifamily.

100,000 = Converts Btus to Therms (btu/Therm)

Other variables as defined above.

For example, a direct-installed kitchen low flow faucet aerator in a fuel DHW single family IQ home:

ΔTherms = 1.0 * (((1.63 * 4.5 – 0.94 * 4.5) * 2.76 * 365.25 *0.75) / 1) * 0.0045 * 0.93

= 9.82 Therms

For example, a direct installed bath low flow faucet aerator in a fuel DHW multifamily non-IQ home:

ΔTherms = 1.0 * (((1.53 * 1.6 – 0.94 * 1.6) * 2.09 * 365.25 * 0.90) /1.5) * 0.0044 * 0.93

= 1.77 Therms

For example, a direct installed low flow faucet aerator in unknown faucet in a fuel DHW single family IQ home:

ΔTherms = 1.0 * (((1.58 * 9.0 – 0.94 * 9.0) * 2.76 * 365.25 * 0.795) /3.83) * 0.0043 * 0.93

= 4.82 Therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

ΔWater (gallons) = ((GPM_base * L_base - GPM_low * L_low) * Household * 365.25 *DF / FPH) * ISR

Variables as defined above

For example, a direct installed kitchen low flow aerator in a single family IQ home

ΔWater (gallons) = (((1.63 * 4.5 – 0.94 * 4.5) * 2.76 * 365.25 *0.75) / 1) * 0.93

= 2,183 gallons

For example, a direct installed bath low flow faucet aerator in a multifamily non-IQ home:

ΔWater (gallons) = (((1.53 * 1.6 – 0.94 * 1.6) * 2.09 * 365.25 * 0.90) /1.5) * 0.93

= 4,02 gallons

For example, a direct installed low flow faucet aerator in unknown faucet in a single family IQ home:

ΔWater (gallons) = (((1.58 * 9.0 – 0.94 * 9.0) * 2.76 * 365.25 * 0.795) /3.83) * 0.93

= 1,121 gallons

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

[945] Water heating in Multifamily buildings is often provided by a larger central boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of 0.59 and the 0.75 for single family homes. An average efficiency of 0.67 is used for this analysis as a default for Multifamily buildings.

REVIEW DEADLINE: 1/1/2030

5.4.5 Low Flow Showerheads

DESCRIPTION

This measure relates to the installation of a low flow showerhead in a single or multi-family household.

This measure may be used for units provided through Efficiency Kits; however, the in-service rate for such measures should be derived through evaluation results specifically for this implementation methodology.

This measure was developed to be applicable to the following program types: TOS, RF, NC, DI, KITS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a low flow showerhead rated at least 0.5 gallons per minute (GPM) less than the existing showerhead. Savings are calculated on a per showerhead fixture basis.

DEFINITION OF BASELINE EQUIPMENT

For Direct install programs, the baseline condition is assumed to be a standard showerhead rated at 2.0 GPM or greater.

For retrofit and time-of-sale programs, the baseline condition is assumed to be a representative average of existing showerhead flow rates of participating customers including a range of low flow showerheads, standard-flow showerheads, and high-flow showerheads.

Average measured flow rates are used in the algorithm and are lower, reflecting the penetration of previously installed low flow fixtures (and therefore the freerider rate for this measure should be 0), use of the shower at less than full flow, debris buildup, and lower water system pressure than fixtures are rated at.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[946]

DEEMED MEASURE COST

For time of sale or new construction the incremental cost for this measure is $7 or program actual.[947]

For low flow showerheads provided through Direct Install or within Efficiency Kits, the actual program delivery costs (including labor if applicable) should be utilized. If unknown assume $12 for Direct Install[948] and $7 for Efficiency Kits.

LOADSHAPE

Loadshape R03 - Residential Electric DHW

COINCIDENCE FACTOR

The coincidence factor for this measure is assumed to be 2.78%.[949]

[946] Table C-6, Measure Life Report, Residential and Commercial/Industrial Lighting and HVAC Measures, GDS Associates, June 2007. Evaluations indicate that consumer dissatisfaction may lead to reductions in persistence, particularly in Multifamily.
[947] Market research average of $7.
[948] Includes assess and install labor time of $5 (20min @ $15/hr)
[949] Calculated as follows: Assume 11% showers take place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.). There are 65 days in the summer peak period, so the percentage of total annual aerator use in peak period is 0.11*65/365 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 369 = 7.23 hours of recovery during peak period, where 369 equals the average annual electric DHW recovery hours for showerhead use including SF and MF homes with Direct Install and Retrofit/TOS measures. There are 260 hours in the peak period so the probability you will see savings during the peak period is 7.23/260 = 0.0278

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Note these savings are per showerhead fixture.

ΔkWh = %ElectricDHW * ((GPM_base * L_base - GPM_low * L_low) * Household * SPCD * 365.25 / SPH) * EPG_electric * ISR

Where:

%ElectricDHW = Percentage of DHW savings assumed to be electric

= 100 % for Electric

= 0 % for Fossil Fuel

= If unknown[950], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	19.7%	30.6%	63.3%	67.3%	31.4%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
People's Gas	2.1%	2.0%	1.7%	2.4%	2.2%
Northshore Gas	1.5%	1.8%	10.0%	2.4%	2.4%
Nicor Gas	7.6%	9.9%	14.4%	22.6%	10.0%
All DUs[951]					**29%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

GPM_base = Average flow rate, in gallons per minute, of the baseline faucet "as-used."

Note, if GPM_base is based upon the deemed assumptions below, since these include participants that had existing low flow fixtures, the freerider rate for this measure should be 0.

Program	GPM_base
Direct Install	2.24[952]
Retrofit, Efficiency Kits, NC or TOS	2.35[953]

[950] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[951] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[952] Based on measurements conducted from June 2013 to January 2014 by Franklin Energy. Over 300 residential sites in the Chicago area were tested.

[953] Representative value from sources 1, 2, 4, 5, 6 and 7 (See Source Table at end of measure section) adjusted slightly upward to account for program participation which is expected to target customers with existing higher flow devices rather than those with existing low flow devices.

GPM_low = As-used flow rate of the low-flow showerhead, which may, as a result of measurements of program evaulations deviate from rated flows[954]

L_base = Shower length in minutes with baseline showerhead

= 7.8 min[955]

L_low = Shower length in minutes with low-flow showerhead

= 7.8 min[956]

Household = Average number of people per household

Household Unit Type	Household[957]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[958]
Custom	Actual Occupancy or Number of Bedrooms[959]		

Use Multifamily if: Building meets utility's definition for multifamily

SPCD = Showers Per Capita Per Day

= 0.6[960]

365.25 = Days per year, on average.

SPH = Showerheads Per Household so that per-showerhead savings fractions can be determined

Household Type	SPH
Single-Family except mobile homes	1.79[961]
Multifamily and mobile homes	1.3[962]
Household type unknown	1.64[963]
Custom	Actual

Use Multifamily if: Building meets utility's definition for multifamily

[954] Note that actual values may be either a) program-specific minimum flow rate, or b) program-specific evaluation-based value of actual effective flow-rate due to increased duration or temperatures. The latter increases in likelihood as the rated flow drops and may become significant at or below rated flows of 1.5 GPM. The impact can be viewed as the inverse of the throttling described in the footnote for baseline flowrate.

[955] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group. This study of 135 single and Multifamily homes in Michigan metered energy parameters for efficient showerhead and faucet aerators.

[956] Ibid.

[957] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.

[958] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.

[959] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

[960] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.

[961] Based on findings from a 2009 ComEd residential survey of 140 sites, provided by Cadmus.

[962] Ibid.

[963] Unknown is based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

EPG_electric = Energy per gallon of hot water supplied by electric

= (8.33 * 1.0 * (ShowerTemp - SupplyTemp)) / (RE_electric * 3,412)

= (8.33 * 1.0 * (101 – 50.7)) / (0.98 * 3,412)

= 0.125 kWh/gal

8.33 = Specific weight of water (lbs/gallon)

1.0 = Heat Capacity of water (btu/lb-°)

ShowerTemp = Assumed temperature of water

= 101°F[964]

SupplyTemp = Assumed temperature of water entering house

= 50.7°F [965]

RE_electric = Recovery efficiency of electric water heater

= 98%[966]

3412 = Converts Btu to kWh (btu/kWh)

ISR = In service rate of showerhead dependant on install method as listed in table below

Selection	ISR
Direct Install	0.965[967]
Virtual Assessment followed by Unverified Self-Install	0.803[968]
Requested Efficiency Kits	0.65[969]
Distributed Efficiency Kits (Income Eligible)	0.48[970]
Distributed School Efficiency Kit showerhead	0.574[971]

[964] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.

[965] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[966] Electric water heaters have recovery efficiency of 98%.

[967] Weighted average of 98% found in ComEd Energy Efficiency/ Demand Response Plan: Plan Year 2 (6/1/2009-5/31/2010) Evaluation Report: All Electric Single Family Home Energy Performance Tune-Up Program Table 3-8 (quantity surveyed = 163), and 87% from ComEd Single Family Retrofits CY2018 Field Work Memo 2019-07-19, Table 1 (quantity surveyed = 15). Alternative ISRs may be developed for program delivery methods based on evaluation results. Navigant, ComEd-Nicor Gas EPY4/GPY1 Multifamily Home Energy Savings Program Evaluation Report FINAL 2013-06-05. Opinion dynamics conducted primary research with tenants of participating multifamily buildings in 2023 to study the removal behavior of tenants post Program Ally direct install of low flow showerheads. Opinion Dynamics, "2023 AIC Multifamily Initiatives Tenant Survey Findings Memo", Ameren Illinois, Multifamily Initiatives, April 24, 2024. These sources have been averaged to arrive at an ISR of 0.965.

[968] An equal weighted average of Direct Install and Efficiency Kit ISRs. Interest and applicability of measures confirmed through virtual assessment. Average of homes using 1 Showerhead & 2 Showerhead.

[969] A weighted ISR was found by weighting Nicor and Ameren efficiency kit program uptake and their previously found ISRs. This analysis can be found in Faucet Aerators and Showerheads Weighted Average ISR IL TRM.xlsx.

[970] Average of Guidehouse survey research for Peoples Gas, June 16, 2020 and Research from 2021 Ameren Illinois Income Qualified participant survey, available on IL SAG website: https://ilsag.s3.amazonaws.com/AIC-Income-Qualified-Initiative-Participant-Survey-Results-Memo-FINAL-2022-02-01.pdf

[971] Results from Home Energy Worksheets completed by student/families in 2020, 2021, and 2022 were nearly the same as values from: Opinion Dynamics and Cadmus. 2018 AIC Residential Program Annual Impact Evaluation Report. April 30, 2019. Results from implementer-administered participant survey. Home Energy Worksheets also establish the fraction of participants who indicate they "will install later" for specific measures. Follow-up research completed by Guidehouse for Nicor Gas in 2022 found

For example, a direct installed 1.5 GPM low flow showerhead in a single family IQ home with electric DHW where the number of showers is not known:

ΔkWh = 1.0 * ((2.24 * 7.8 – 1.5 * 7.8) * 2.76 * 0.6 * 365.25 / 1.79) * 0.125 * 0.96

= 234 kWh

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) / 1{,}000{,}000 * E_{water\ total}$$

Where

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

= 5,010[972]

For example, a direct installed 1.5 GPM low flow showerhead in a single family IQ home where the number of showers is not known:

ΔWater (gallons) = ((2.24 * 7.8 – 1.5 * 7.8) * 2.76 * 0.6 * 365.25 / 1.79) * 0.96

= 1,872 gallons

ΔkWh_{water} = 1,872/1,000,000 * 5,010

= 9.4 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh/Hours * CF

Where:

ΔkWh = calculated value above. Note do not include the secondary savings in this calculation.

Hours = Annual electric DHW recovery hours for showerhead use

= ((GPM_base * L_base) * Household * SPCD * 365.25) * 0.726[973] / GPH

= 273 for SF Direct Install; 224 for MF Direct Install

= 286 for SF Retrofit, Efficiency Kits, NC and TOS; 236 for MF Retrofit, Efficiency Kits, NC and TOS

Use Multifamily if: Building meets utility's definition for multifamily

GPH = Gallons per hour recovery of electric water heater calculated for 69.3F temp rise (120-50.7), 98% recovery efficiency, and typical 4.5kW electric resistance storage tank.

= 26.1

CF = Coincidence Factor for electric load reduction

that, on average, 51.3% of respondents who initially reported that they hadn't installed specific kit measures, but "planned to" subsequently had installed the measures. Combining these findings allows for an ISR that accounts for initial and one round of subsequent intallations. To maintain a conservative estimate of ISR, the remaining 48.7% are presumed uninstalled. See: EESchoolKitSubsequentInstall_HEW.xlsx for data and calculations.

[972] This factor includes 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

[973] 72.6% is the proportion of hot 120F water mixed with 50.7F supply water to give 101F shower water.

= 0.0278[974]

For example, a direct installed 1.5 GPM low flow showerhead in a single family IQ home with electric DHW where the number of showers is not known:

ΔkW = 234/273 * 0.0278

= 0.024 kW

FOSSIL FUEL SAVINGS

ΔTherms = %FossilDHW * ((GPM_base * L_base - GPM_low * L_low) * Household * SPCD * 365.25 / SPH) * EPG_gas * ISR

Where:

%FossilDHW = Percentage of DHW savings assumed to be fossil fuel

= 100 % for Fossil Fuel

= 0 % for Electric

= If unknown[975], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs[976]					**71%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

EPG_gas = Energy per gallon of Hot water supplied by gas

= (8.33 * 1.0 * (ShowerTemp - SupplyTemp)) / (RE_gas * 100,000)

= 0.0054 Therm/gal for SF homes

= 0.0063 Therm/gal for MF homes

RE_gas = Recovery efficiency of gas water heater

[974] Calculated as follows: Assume 11% showers take place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.). There are 65 days in the summer peak period, so the percentage of total annual aerator use in peak period is 0.11*65/365 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 369 = 7.23 hours of recovery during peak period where 369 equals the average annual electric DHW recovery hours for showerhead use including SF and MF homes with Direct Install and Retrofit/TOS measures. There are 260 hours in the peak period so the probability you will see savings during the peak period is 7.23/260 = 0.0278

[975] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[976] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

= 78% For individual water heater[977]

= 67% For shared water heater[978]

If unknown, use individual water heater value for single family, use shared water heater value for multifamily. Use multifamily if building meets utility's definition for multifamily.

100,000 = Converts Btus to Therms (btu/Therm)

Other variables as defined above.

For example, a direct installed 1.5 GPM low flow showerhead in a gas fired DHW single family home where the number of showers is not known:

ΔTherms = 1.0 * ((2.24 * 7.8 – 1.5 * 7.8) * 2.76 * 0.6 * 365.25 / 1.79) * 0.0054 * 0.96

= 10.1 therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

ΔWater (gallons) = ((GPM_base * L_base - GPM_low * L_low) * Household * SPCD * 365.25 / SPH) * ISR

Variables as defined above

For example, a direct installed 1.5 GPM low flow showerhead in a single family home where the number of showers is not known:

ΔWater (gallons) = ((2.24 * 7.8 – 1.5 * 7.8) * 2.76 * 0.6 * 365.25 / 1.79) * 0.96

= 1,872 gallons

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

SOURCES

[977] DOE Final Rule discusses Recovery Efficiency with an average around 0.76 for Gas Fired Storage Water heaters and 0.78 for standard efficiency gas fired tankless water heaters up to 0.95 for the highest efficiency gas fired condensing tankless water heaters. These numbers represent the range of new units however, not the range of existing units in stock. Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 78%.

[978] Water heating in Multifamily buildings is often provided by a larger central boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of 0.59 and the 0.75 for single family homes. An average efficiency of 0.67 is used for this analysis as a default for Multifamily buildings.

REVIEW DEADLINE: 1/1/2030

5.4.6 Water Heater Temperature Setback

DESCRIPTION

This measure was developed to be applicable to the following program types: NC, RF, DI, KITS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

High efficiency is a hot water tank with the thermostat reduced to no lower than 120 degrees.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a hot water tank with a thermostat setting that is higher than 120 degrees, typically systems with settings of 130 degrees or higher. Note if there are more than one DHW tanks in the home at or higher than 130 degrees and they are all turned down, then the savings per tank can be multiplied by the number of tanks.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The assumed lifetime of the measure is 2 years.

DEEMED MEASURE COST

The incremental cost of a setback is assumed to be $5 for contractor time, or where the measure is installed as part of a kit program, the cost of the informational insert or other product should be used.

LOADSHAPE

Loadshape R03 - Residential Electric DHW

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 1.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

For homes with electric DHW tanks:

$$\Delta kWh^{979} = (U * A * (Tpre - Tpost) * Hours * ISR) / (3412 * RE_electric)$$

Where:

U = Overall heat transfer coefficient of tank (Btu/Hr-°F-ft^2).

= Actual if known. If unknown assume R-12, U = 0.083

A = Surface area of storage tank (square feet)

= Actual if known. If unknown use table below based on capacity of tank. If capacity unknown assume 50 gal tank; A = 24.99ft^2

[979] Note this algorithm provides savings only from reduction in standby losses. The TAC considered avoided energy from not heating the water to the higher temperature but determined that dishwashers are likely to boost the temperature within the unit (roughly canceling out any savings), faucet and shower use is likely to be at the same temperature so there would need to be more lower temperature hot water being used (cancelling any savings) and clothes washers will only see savings if the water from the tank is taken without any temperature control. It was felt the potential impact was too small to be characterized.

Capacity (gal)	A (ft^2)[980]
30	19.16
40	23.18
50	24.99
80	31.84

Tpre = Actual hot water setpoint prior to adjustment

Tpost = Actual new hot water setpoint, which may not be lower than 120 degrees

Default Hot Water Temperature Inputs			
Delivery Method	**System Type**	**Tpre**	**Tpost**
Distributed school efficient kit instructions, Instructions provided in all other kit programs[981, 982]	Electric	143.0	139.1

	Gas	2.94
	Other	1.69
Non-kit program	All	120.72

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh / Hours * CF

Where:

Hours = 8766

CF = Summer Peak Coincidence Factor for measure

= 1

Deemed savings assumptions for kit programs and non-kit programs are provided in the table below:

Deemed kW Savings		
Delivery Method	**System Type**	**ΔkW**
Distributed school efficient kit instructions	Electric	0.0005
	Gas	0.0007
	Other	0.0004
All other kit programs	Electric	0.0002
	Gas	0.0003
	Other	0.0002
Non-kit program	All	0.0138

FOSSIL FUEL SAVINGS

For homes with gas water heaters:

ΔTherms = (U * A * (Tpre – Tpost) * Hours * ISR) / (100,000 * RE_gas)

Where

100,000 = Converts Btus to Therms (btu/Therm)

RE_gas = Recovery efficiency of gas water heater

= 78% For SF homes [987]

[987] DOE Final Rule discusses Recovery Efficiency with an average around 0.76 for Gas Fired Storage Water heaters and 0.78 for standard efficiency gas fired tankless water heaters up to 0.95 for the highest efficiency gas fired condensing tankless water heaters. These numbers represent the range of new units however, not the range of existing units in stock. Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 78%.

= 67% For MF homes[988]

Use Multifamily if: Building has shared DHW

Deemed savings for kit programs and non-kit programs, for both single-family and multi-family settings, are provided in the table below:

Deemed Fossil Fuel Savings			
Delivery Method	**System Type**	**ΔTherms SF**	**ΔTherms MF**

REVIEW DEADLINE: 1/1/2028

[988] Water heating in Multifamily buildings is often provided by a larger central boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of 0.59 and the 0.75 for single family homes. An average efficiency of 0.67 is used for this analysis as a default for Multifamily buildings.

5.4.7 Water Heater Wrap

DESCRIPTION

This measure relates to a Tank Wrap or insulation "blanket" that is wrapped around the outside of a hot water tank to reduce stand-by losses. This measure applies only for homes that have an electric water heater that is not already well insulated. Generally this can be determined based upon the appearance of the tank,[989] or by touching the tank[990].

This measure was developed to be applicable to the following program types: RF, DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The measure is a properly installed, R-8 or greater insulating tank wrap to reduce standby energy losses from the tank to the surrounding ambient area.

DEFINITION OF BASELINE EQUIPMENT

The baseline is a standard electric domestic hot water tank without an additional tank wrap. Gas storage water heaters are excluded due to the limitations of retrofit wrapping and the associated impacts on reduced savings and safety.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 5 years.[991]

DEEMED MEASURE COST

The incremental cost for this measure will be the actual material cost of procuring and labor cost of installing the tank wrap.

LOADSHAPE

Loadshape R03 - Residential Electric DHW

COINCIDENCE FACTOR

This measure assumes a flat loadshape and as such the coincidence factor is 1.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

For electric DHW systems:

$$\Delta kWh = ((1/ Rbase - 1 / R_{insul}) * A_{base} * \Delta T * Hours) / (3412 * \eta DHW)$$

Where:

R_{base} = Overall thermal resistance coefficient prior to adding tank wrap (Hr-°F-ft^2/BTU).

R_{insul} = Overall thermal resistance coefficient after addition of tank wrap (Hr-°F-ft^2/BTU).

[989] Visually determine whether it is insulated by foam (newer, rigid, and more effective) or fiberglass (older, gives to gently pressure, and not as effective)

[990] If the tank is warm to the touch, consider insulation.

[991] This estimate assumes the tank wrap is installed on an existing unit with 5 years remaining life.

A_{base} = Surface area of storage tank prior to adding tank wrap (square feet)[992]

ΔT = Average temperature difference between tank water and outside air temperature (°F)

= 60°F [993]

Hours = Number of hours in a year (since savings are assumed to be constant over year).

= 8766

3412 = Conversion from Btu to kWh

ηDHW = Recovery efficiency of electric hot water heater

= 0.98 [994]

The following table has default savings for various tank capacity and pre and post R-VALUES.

Capacity (gal)	Rbase	Rinsul	Abase (ft2)[995]	ΔkWh	ΔkW
30	8	16	19.16	188	0.0215
30	10	18	19.16	134	0.0153
30	12	20	19.16	100	0.0115
30	8	18	19.16	209	0.0239
30	10	20	19.16	151	0.0172

REVIEW DEADLINE: 1/1/2030

5.4.8 Thermostatic Restrictor Shower Valve

DESCRIPTION

The measure is the installation of a thermostatic restrictor shower valve in a single or multi-family household. This is a valve attached to a residential showerhead which restricts hot water flow through the showerhead once the water reaches a set point (generally 95F or lower).

This measure was developed to be applicable to the following program types: RF, NC, DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be a thermostatic restrictor shower valve installed on a residential showerhead.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is the residential showerhead without the restrictor valve installed.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[996]

DEEMED MEASURE COST

The incremental cost of the measure should be the actual program cost (including labor if applicable), or $35[997] plus $20 labor[998] if not available.

LOADSHAPE

Loadshape R03 - Residential Electric DHW

COINCIDENCE FACTOR

The coincidence factor for this measure is assumed to be 0.22%.[999]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \%ElectricDHW * ((GPM_base_S * L_showerdevice) * Household * SPCD * 365.25 / SPH) * EPG_electric * ISR$$

Where:

%ElectricDHW = Percentage of DHW savings assumed to be electric

[996] Assumptions based on NY TRM, Pacific Gas and Electric Company Work Paper PGECODHW113, and measure life of low-flow showerhead.
[997] Based on actual cost of the showerstart tsv3 adapter from Evolve showerheads.
[998] Estimate for contractor installation time.
[999] Calculated as follows: Assume 11% showers take place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.). There are 65 days in the summer peak period, so the percentage of total annual use in peak period is 0.11*65/365 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 29.5 = 0.577 hours of recovery during peak period, where 29.5 equals the average annual electric DHW recovery hours for showerhead use prevented by the device including SF and MF homes with Direct Install and Retrofit/TOS measures. There are 260 hours in the peak period so the probability you will see savings during the peak period is 0.577/260 = 0.0022

= 100 % for Electric

= 0 % for Fossil Fuel

= If unknown[1000], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	19.7%	30.6%	63.3%	67.3%	31.4%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
People's Gas	2.1%	2.0%	1.7%	2.4%	2.2%
Northshore Gas	1.5%	1.8%	10.0%	2.4%	2.4%
Nicor Gas	7.6%	9.9%	14.4%	22.6%	10.0%
All DUs[1001]					**29%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

GPM_base_S = Flow rate of the basecase showerhead, or actual if available

Program	GPM
Direct-install, device only	2.24[1002]
New Construction or direct install of device and low flow showerhead	Rated or actual flow of program-installed showerhead
Retrofit or TOS	2.35[1003]

L_showerdevice = Hot water waste time avoided due to thermostatic restrictor valve

= 0.89 minutes[1004]

Household = Average number of people per household

Household Unit Type	Household[1005]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18

[1000] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1001] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[1002] Based on measurements conducted from June 2013 to January 2014 by Franklin Energy. Over 300 residential sites in the Chicago area were tested.

[1003] Representative value from sources 1, 2, 4, 5, 6 and 7 (See Source Table at end of measure section) adjusted slightly upward to account for program participation which is expected to target customers with existing higher flow devices rather than those with existing low flow devices.

[1004] Average of the following sources: ShowerStart LLC survey; "Identifying, Quantifying and Reducing Behavioral Waste in the Shower: Exploring the Savings Potential of ShowerStart", City of San Diego Water Department survey; "Water Conservation Program: ShowerStart Pilot Project White Paper", and PG&E Work Paper PGECODHW113.

[1005] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.

Household Unit Type	Household[1005]		
	IQ Participants	Non-IQ Participants	All Participants
Household type unknown			2.46[1006]
Custom	Actual Occupancy or Number of Bedrooms[1007]		

Use Multifamily if: Building meets utility's definition for multifamily

SPCD = Showers Per Capita Per Day

= 0.6[1008]

365.25 = Days per year, on average.

SPH = Showerheads Per Household so that per-showerhead savings fractions can be determined

Household Type	SPH
Single-Family	1.79[1009]
Multifamily	1.3[1010]
Household type unknown	1.64[1011]
Custom	Actual

Use Multifamily if: Building meets utility's definition for multifamily

EPG_electric = Energy per gallon of hot water supplied by electric

= (8.33 * 1.0 * (ShowerTemp - SupplyTemp)) / (RE_electric * 3412)

= (8.33 * 1.0 * (101 – 50.7)) / (0.98 * 3412)

= 0.125 kWh/gal

8.33 = Specific weight of water (lbs/gallon)

1.0 = Heat Capacity of water (btu/lb-°)

ShowerTemp = Assumed temperature of water

= 101F [1012]

SupplyTemp = Assumed temperature of water entering house

= 50.7°F [1013]

RE_electric = Recovery efficiency of electric water heater

[1006] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.
[1007] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.
[1008] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.
[1009] Based on findings from a 2009 ComEd residential survey of 140 sites, provided by Cadmus.
[1010] Ibid.
[1011] Unknown is based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.
[1012] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.
[1013] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

= 98% [1014]

3412 = Converts Btu to kWh (btu/kWh)

ISR = In service rate of showerhead

= Dependent on program delivery method as listed in table below

Selection	ISR
Direct Install - Single Family	0.98[1015]
Direct Install – Multi Family	0.95[1016]
Efficiency Kits	To be determined through evaluation

Use Multifamily if: Building meets utility's definition for multifamily

For example, a direct installed valve in a single-family IQ home with electric DHW:

ΔkWh = 1.0 * (2.24 * 0.89 * 2.76 * 0.6 * 365.25 / 1.79) * 0.125 * 0.98

= 82.5 kWh

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

ΔkWh_{water} = ΔWater (gallons) / 1,000,000 * $E_{water\ total}$

Where

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

=5,010[1017]

For example, a direct installed thermostatic restrictor device in a single family IQ home where the number of showers is not known:

ΔWater (gallons) = ((2.24* 0.89) * 2.76 * 0.6 * 365.25 / 1.79) * 0.98

= 660 gallons

ΔkWh_{water} = 660/1,000,000 * 5,010

= 3.3 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh/Hours * CF

Where:

ΔkWh = calculated value above. Note do not include the secondary savings in this calculation.

[1014] Electric water heaters have recovery efficiency of 98%.

[1015] Deemed values are from ComEd Energy Efficiency/ Demand Response Plan: Plan Year 2 (6/1/2009-5/31/2010) Evaluation Report: All Electric Single Family Home Energy Performance Tune-Up Program Table 3-8. Alternative ISRs may be developed for program delivery methods based on evaluation results.

[1016] Navigant, ComEd-Nicor Gas EPY4/GPY1 Multifamily Home Energy Savings Program Evaluation Report FINAL 2013-06-05

[1017] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

Hours = Annual electric DHW recovery hours for wasted showerhead use prevented by device

= ((GPM_base_S * L_showerdevice) * Household * SPCD * 365.25) * 0.726[1018] / GPH

GPH = Gallons per hour recovery of electric water heater calculated for 69.3F temp rise (120-50.7), 98% recovery efficiency, and typical 4.5kW electric resistance storage tank.

= 26.1

= 31.1 for SF Direct Install; 25.5 for MF Direct Install

= 32.6 for SF Retrofit and TOS; 26.7 for MF Retrofit and TOS

Use Multifamily if: Building meets utility's definition for multifamily

CF = Coincidence Factor for electric load reduction

= 0.0022[1019]

For example, a direct installed thermostatic restrictor device in a single family IQ home with electric DHW where the number of showers is not known.

ΔkW = 82.5/31.1 * 0.0022

= 0.0058 kW

FOSSIL FUEL SAVINGS

ΔTherms = %FossilDHW * ((GPM_base_S * L_showerdevice)* Household * SPCD * 365.25 / SPH) * EPG_gas * ISR

Where:

%FossilDHW = Percentage of DHW savings assumed to be fossil fuel

= 100 % for Fossil Fuel

= 0 % for Electric

= If unknown[1020], use the following table:

	Location				
Utility	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%

[1018] 72.6% is the proportion of hot 120F water mixed with 50.7F supply water to give 101F shower water.

[1019] Calculated as follows: Assume 11% showers take place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.). There are 65 days in the summer peak period, so the percentage of total annual use in peak period is 0.11*65/365 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 29.5 = 0.577 hours of recovery during peak period, where 29.5 equals the average annual electric DHW recovery hours for showerhead use prevented by the device including SF and MF homes with Direct Install and Retrofit/TOS measures. There are 260 hours in the peak period so the probability you will see savings during the peak period is 0.577/260 = 0.0022

[1020] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

	Location				
Utility	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs[1021]					**71%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

EPG_gas = Energy per gallon of Hot water supplied by gas

= (8.33 * 1.0 * (ShowerTemp - SupplyTemp)) / (RE_gas * 100,000)

= 0.0054 Therm/gal for SF homes

= 0.0063 Therm/gal for MF homes

RE_gas = Recovery efficiency of gas water heater

= 78% For SF homes[1022]

= 67% For MF homes[1023]

Use Multifamily if: Building has shared DHW.

100,000 = Converts Btus to Therms (btu/Therm)

Other variables as defined above.

For example, a direct installed thermostatic restrictor device in a gas fired DHW single family IQ home where the number of showers is not known:

ΔTherms = 1.0 * ((2.24 * 0.89) * 2.76 * 0.6 * 365.25 / 1.79) * 0.0054 * 0.98

= 3.6 therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

ΔWater (gallons) = ((GPM_base_S * L_showerdevice) * Household * SPCD * 365.25 / SPH) * ISR

Variables as defined above

[1021] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

[1022] DOE Final Rule discusses Recovery Efficiency with an average around 0.76 for Gas Fired Storage Water heaters and 0.78 for standard efficiency gas fired tankless water heaters up to 0.95 for the highest efficiency gas fired condensing tankless water heaters. These numbers represent the range of new units however, not the range of existing units in stock. Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 78%.

[1023] Water heating in Multifamily buildings is often provided by a larger central boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of 0.59 and the 0.75 for single family homes. An average efficiency of 0.67 is used for this analysis as a default for Multifamily buildings.

For example, a direct installed thermostatic restrictor device in a single family IQ home where the number of showers is not known:

ΔWater (gallons) = ((2.24 * 0.89) * 2.76 * 0.6 * 365.25 / 1.79) * 0.98

= 660 gallons

5.4.9 Shower Timer

DESCRIPTION

Shower Timers are designed to make it easy for people to consistently take short showers, resulting in water and energy savings.

The shower timer provides a reminder to participants on length of their shower visually or auditorily.

This measure was developed to be applicable to the following program type: KITS, DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The shower timer should provide a reminder to participants to keep showers to a length of 5 minutes or less.

DEFINITION OF BASELINE EQUIPMENT

The baseline is no shower timer.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The deemed lifetime is 2 years.[1024]

DEEMED MEASURE COST

For shower timers provided in Efficiency Kits, the actual program delivery costs should be utilized.

LOADSHAPE

Loadshape R03 - Residential Electric DHW

COINCIDENCE FACTOR

The coincidence factor for this measure is assumed to be 2.78%.[1025]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \%ElectricDHW * GPM * (L_{base} - L_{timer}) * Household * Days/yr * SPCD * UsageFactor * EPG_{Electric}$$

Where:

%Electric DHW = Percentage of DHW savings assumed to be electric

= 100 % for Electric

= 0 % for Fossil Fuel

[1024] Estimate of persistence of behavior change instigated by the shower timer.

[1025] Calculated as follows: Assume 11% showers take place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.). There are 65 days in the summer peak period, so the percentage of total annual aerator use in peak period is 0.11*65/365 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 369 = 7.23 hours of recovery during peak period, where 369 equals the average annual electric DHW recovery hours for showerhead use including SF and MF homes with Direct Install and Retrofit/TOS measures. There are 260 hours in the peak period so the probability you will see savings during the peak period is 7.23/260 = 0.0278

= If unknown[1026], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	19.7%	30.6%	63.3%	67.3%	31.4%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
People's Gas	2.1%	2.0%	1.7%	2.4%	2.2%
Northshore Gas	1.5%	1.8%	10.0%	2.4%	2.4%
Nicor Gas	7.6%	9.9%	14.4%	22.6%	10.0%
All DUs[1027]					**29%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

GPM = Flow rate of showerhead as used

= Custom, to be determined through evaluation. If data is not available use 1.93[1028]

L_base = Number of minutes in shower without a shower timer

=7.8 minutes[1029]

L_timer = Number of minutes in shower after shower timer

= Custom, to be determined through evaluation. If data is not available use 5.79.[1030]

Household = Number in household using timer

Household Unit Type	Household[1031]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[1032]
Custom	Actual Occupancy or Number of Bedrooms[1033]		

Days/yr = 365.25

SPCD = Showers Per Capita Per Day

[1026] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1027] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[1028] Navigant Elementary Education GPY4 Evaluation Report, dated May 12, 2016. Average of all utilities.

[1029] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group. This study of 135 single and Multifamily homes in Michigan metered energy parameters for efficient showerhead and faucet aerators.

[1030] Navigant Elementary Education GPY4 Evaluation Report, dated May 12, 2016. Average of all utilities.

[1031] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.

[1032] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.

[1033] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

= 0.6[1034]

UsageFactor = How often each participant is using shower timer

=Custom, to be determined through evaluation. If data is not available use 0.34[1035]

EPG_Electric = Energy per gallon of hot water supplied by electric

= (8.33 * 1.0 * (ShowerTemp - SupplyTemp)) / (RE_electric * 3412)

= (8.33 * 1.0 * (101 – 50.7)) / (0.98 * 3412)

=0.125 kWh/gal

Where:

ShowerTemp = Assumed temperature of water

= 101°F[1036]

SupplyTemp = Assumed temperature of water entering house

= 50.7°F [1037]

Based on default assumptions provided above, the savings for a single family IQ home would be:

ΔkWh = %Electric DHW * GPM * (L_base – L_timer) * Household * Days/yr * SPCD * UsageFactor * EPG_Electric

= 0.25 * 1.93 * (7.8 – 5.79) * 2.76 * 365.25 * 0.6 * 0.34 * 0.125

= 24.9 kWh

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

ΔkWh_{water} = ΔWater (gallons) / 1,000,000 * $E_{water\ total}$

Where

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

=5,010[1038]

Based on default assumptions provided above, the savings for a single family IQ home would be:

ΔWater (gallons) = GPM * (L_base – L_timer) * Household ***** Days/yr * SPCD * UsageFactor

= 1.93 * (7.8 – 5.79) * 2.76 * 365.25 * 0.6 * 0.34

= 797.8 gallons

[1034] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.

[1035] Navigant Elementary Education GPY4 Evaluation Report, dated May 12, 2016. Average of all utilities.

[1036] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.

[1037] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[1038] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

ΔkWh_{water} = 797.8/1,000,000 * 5010

= 4.0 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ΔkWh/Hours * CF

Where:

ΔkWh = calculated value above. Note do not include the secondary savings in this calculation.

Hours = Annual electric DHW recovery hours for showerhead use

= (GPM_base * L_base * Household * SPCD * UsageFactor * 365.25) * 0.726 [1039] / GPH

GPH = Gallons per hour recovery of electric water heater calculated for 69.3F temp rise (120-50.7), 98% recovery efficiency, and typical 4.5kW electric resistance storage tank.

= 26.1

CF = Coincidence Factor for electric load reduction

= 0.0278[1040]

Based on default assumptions provided above, the savings for a single family IQ home would be:

Hours = (1.93 * 7.8 * 2.76 * 0.6 * 0.34 * 365.25) * 0.726/26.1

= 86.1 Hours

ΔkW = ΔkWh/Hours * CF

= 24.9 / 86.1 * 0.0278

= 0.0080 kW

FOSSIL FUEL SAVINGS

ΔTherms = %FossilDHW * GPM * (L_base – L_timer) * Household ***** Days/yr * SPCD * UsageFactor * EPG_Gas

%FossilDHW = Percentage of DHW savings assumed to be fossil fuel

= 100 % for Fossil Fuel

= 0 % for Electric

= If unknown[1041], use the following table:

	Location				
Utility	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%

[1039] 72.6% is the proportion of hot 120F water mixed with 50.7F supply water to give 101F shower water.

[1040] Calculated as follows: Assume 11% showers take place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.). There are 65 days in the summer peak period, so the percentage of total annual aerator use in peak period is 0.11*65/365 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 369 = 7.23 hours of recovery during peak period where 369 equals the average annual electric DHW recovery hours for showerhead use including SF and MF homes with Direct Install and Retrofit/TOS measures. There are 260 hours in the peak period so the probability you will see savings during the peak period is 7.23/260 = 0.0278

[1041] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

	Location				
Utility	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs[1042]					**71%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

EPG_gas = Energy per gallon of Hot water supplied by gas

= (8.33 * 1.0 * (ShowerTemp - SupplyTemp)) / (RE_gas * 100,000)

= 0.00537 Therm/gal for SF homes

= 0.00625 Therm/gal for MF homes

RE_gas = Recovery efficiency of gas water heater

= 78% For SF homes [1043]

= 67% For MF homes[1044]

Use Multifamily if: Building has shared DHW.

100,000 = Converts Btus to Therms (btu/Therm)

Other variables as defined above.

Based on default assumptions provided above, the savings for a single family IQ home would be:

Δ Therms = %FossilDHW * GPM * (L_base – L_timer) * Household ***** Days/yr * SPCD * UsageFactor * EPG_Gas

= 0.75 * 1.93 * (7.8 – 5.79) * 2.76 * 365.25 * 0.6 * 0.34 * 0.00537

= 3.2 Therms

WATER DESCRIPTIONS AND CALCULATION

ΔWater (gallons) = GPM * (L_base – L_timer) * Household ***** Days/yr * SPCD * UsageFactor

Variables as defined above

Based on default assumptions provided above, the savings for a single family home would be:

ΔWater (gallons) = GPM * (L_base – L_timer) * Household ***** Days/yr * SPCD * UsageFactor

[1042] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

[1043] DOE Final Rule discusses Recovery Efficiency with an average around 0.76 for Gas Fired Storage Water heaters and 0.78 for standard efficiency gas fired tankless water heaters up to 0.95 for the highest efficiency gas fired condensing tankless water heaters. These numbers represent the range of new units however, not the range of existing units in stock. Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 78%.

[1044] Water heating in Multifamily buildings is often provided by a larger central boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of 0.59 and the 0.75 for single family homes. An average efficiency of 0.67 is used for this analysis as a default for Multifamily buildings.

= 1.93 * (7.8 – 5.79) * 2.76 * 365.25 * 0.6 * 0.34

= 797.8 gallons

5.4.10 Pool Covers

DESCRIPTION

This measure refers to the installation of covers on residential use pools that are heated with gas-fired equipment located either indoors or outdoors. By installing pool covers, the heating load on the pool boiler will be reduced by reducing the heat loss from the water to the environment and the amount of actual water lost due to evaporation (which then requires additional heated water to make up for it). An additional benefit to pool covers are the electricity savings from the reduced fresh water required to replace the evaporated water.

The main source of energy loss in pools is through evaporation. This is particularly true of outdoor pools where wind plays a larger role. The point of installing pool covers is threefold. First, it will reduce convective losses due to the wind by shielding the water surface. Second, it will insulate the water from the colder surrounding air. And third, it will reduce radiative losses to the night sky. In doing so, evaporative losses will also be minimized, and the boiler will not need to work as hard in replenishing the pool with hot water to keep the desired temperature.

This measure can be used for pools that (1) currently do not have pool covers, (2) have pool covers that are past the useful life of the existing cover, or (3) have pool covers that are past their warranty period and have failed.

This measure was developed to be applicable to the following program type: RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

For indoor pools, the efficient case is the installation of an indoor pool cover with a 5 year warranty on an indoor pool that is used all year.

For outdoor pools, the efficient case is the installation of an outdoor pool cover with a 5 year warranty on an outdoor pool that is used through the summer season.

DEFINITION OF BASELINE EQUIPMENT

For indoor pools, the base case is an uncovered indoor pool that operates all year.

For outdoor pools, the base case is an outdoor pool that is uncovered and is open through the summer season.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The useful life of this measure is assumed to be 6 years.[1045]

DEEMED MEASURE COST

The table below shows the costs for the various options and cover sizes. Since this measure covers a mix of various sizes, the average cost of these options is taken to be the incremental measure cost. [1046] Costs are per square foot.

Cover Size	Edge Style	
	Hemmed (indoor)	Weighted (outdoor)
1-299 sq. ft.	$3.86	$3.12
300-999 sq. ft.	$3.50	$2.16
Average	$3.68	$2.64

LOADSHAPE

Loadshape R15 – Residential Pool Pumps

[1045] The effective useful life of a pool cover is typically one year longer than its warranty period. SolaPool Covers. Pool Covers Website, FAQ- "How long will my SolaPool cover blanket last?". Pool covers are typically offered with 3 and 5 year warranties with at least one company offering a 6 year warranty. Conversation with Trade Ally. Knorr Systems

[1046] Pool Cover Costs derived from three leading online realtors, see Pool Covers Costs.xlsx .

COINCIDENCE FACTOR

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) / 1{,}000{,}000 * E_{water\ supply}$$

Where

$E_{water\ supply}$ = Water Supply Energy Factor (kWh/Million Gallons)

= 2,571[1047]

For example**:**

For a 392 ft2 Indoor Swimming Pool:

ΔWater = WaterSavingFactor x Size of Pool

= 15.28 gal./ft2/year x 392 ft2

= 5,990 gal./year

ΔkWhwater = ΔWater / 1,000,000 * Ewater total

= 5,990 gal./year / 1,000,000 * 2,571 kWh/million gallons

= 15.4 kWh/year

For a 392 ft2 Outdoor Swimming Pool:

ΔWater = WaterSavingFactor x Size of Pool

= 8.94 gal./ft2/year x 392 ft2

= 3,504 gal./year

ΔkWhwater = ΔWater / 1,000,000 * $E_{water\ supply}$

= 3,504 gal./year / 1,000,000 * 2,571 kWh/million gallons

= 9.0 kWh/year

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

The calculations are based on modeling runs using RSPEC! Energy Smart Pools Software that was created by the U.S. Department of Energy. [1048]

[1047] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'. Note since the water loss associated with this measure is due to evaporation and does not discharge into the wastewater system, only the water supply factor is used here.

[1048] Full method and supporting information found in reference document: IL TRM – Residential Pool Covers WorkPaper.docx. Note that the savings estimates are based upon Chicago weather data.

ΔTherms = SavingFactor x Size of Pool

Where

Savings factor = dependant on pool location and listed in table below:[1049]

Location	Therm / sq-ft
Indoor	2.61
Outdoor	1.01

Size of Pool = Actual. If unknown assume 392 ft^2 [1050]

WATER IMPACT DESCRIPTIONS AND CALCULATION

ΔWater (gallons) = WaterSavingFactor x Size of Pool

Where

WaterSavingFactor = Water savings for this measure dependant on pool location and listed in table below:[1051]

Location	Annual Savings Gal / sq-ft
Indoor	15.28
Outdoor	8.94

Size of Pool = 392 ft^2

DEEMED O&M COST ADJUSTMENT CALCULATION

There are no O&M cost adjustments for this measure.

MEASURE CODE: RS-HWE-PLCV-V02-240101

REVIEW DEADLINE: 1/1/2029

[1049] Calculations can be found in Residential Pool Covers.xlsx

[1050] The average size of an installed in-ground swimming poll is 14 ft x 28 ft, giving a surface area of 392 ft^2. <https://www.homeadvisor.com/cost/swimming-pools-hot-tubs-and-saunas/inground-pool/>

5.4.11 Drain Water Heat Recovery

DESCRIPTION

Drain Water Heat Recovery (DWHR) is a technology that captures waste heat in the drain line during a shower event, using the reclaimed heat to preheat cold water that is then delivered either to the shower or the water heater. The device can be installed in either an equal flow configuration (with preheated water being routed to both the water heater and the shower) or an unequal flow configuration (preheated water directed to either the water heater or shower). The energy harvested from a DWHR device is maximized in an equal flow configuration. It uses a non-regenerative heat exchanger to pre-heat the incoming cold fresh water with the outgoing warm drain water. It has been proven that DWHR devices only recover energy during simultaneous draws,[1052] i.e., showers, and that for energy savings purposes all other water draws can be ignored. Savings are calculated per drain water heat recovery unit. Other benefits include increased first-hour rating of water tank, improved comfort due to slower temperature degradation at run-out and reduction of coincident peak demand.[1053]

This measure was developed to be applicable to the following program types: RF, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Efficient equipment is a DWHR unit retrofitted to the main drain which includes outlets from showers, sinks and other fixtures too. Note, that the DWHR unit can either be installed in a vertical configuration or a horizontal configuration. Although, this measure covers both horizontal and vertical DWHR,[1054] the energy savings calculations focuses on vertical. Due to the lack of any moving parts, no maintenance is required for either types of DWHR units. Vertical units are said to comprise 95% of the market currently.[1055]

The device can be installed in either an equal flow configuration or an unequal flow configuration. An equal flow installation is ideal with all the incoming cold water passing through the DWHR heat exchanger apparatus, after which it splits into cold water and inlet to water heater. Units should be installed in single-family homes and multi-family homes.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a storage type water heater without DWHR devices in a residential application.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 30 years.[1056]

DEEMED MEASURE COST

The incremental cost for this measure is $744 per unit.[1057]

COINCIDENCE FACTOR

The coincidence factor for this measure is assumed to be 2.78%.[1058]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

For electric water heating, annual energy savings per unit are calculated through the following formula:

$$\Delta kWh = \frac{(ShowerTemp - SupplyTemp) * 8.33\frac{BTU}{gal\cdot°F} * GPM * T_{shower-length} * Household * N_{units} * \text{SPCD} * 365.25\frac{days}{yr} * SF}{3412\frac{BTU}{kWh} * RE}$$

Where:

ShowerTemp = assumed water temperature during shower
= 101°F[1059]

SupplyTemp = assumed temperature of cold water entering house
= 50.7°F[1060]

8.33 = Energy required (BTU) to heat one gallon of water by one degree Fahrenheit

GPM = gallon per minute, flow rate of showerhead
= 2.35 Gallon/minute[1061]

$T_{shower-length}$ = shower length in minutes
= 7.8 minutes[1062]

Household = average number of people per household

Household Unit Type	Household[1063]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[1064]

[1058] Assume coincidence factor for DWHR units is the same with that of low flow showerheads (see Illinois Statewide Technical Reference Manual for Energy Efficiency, section 5.4.5, low flow showerheads)

[1062] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group. This study of 135 single and Multifamily homes in Michigan metered energy parameters for efficient showerhead and faucet aerators.
[1063] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.
[1064] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.

Household Unit Type	Household[1063]		
	IQ Participants	Non-IQ Participants	All Participants
Custom	Actual Occupancy or Number of Bedrooms[1065]		

N_{units} = Number of units in a multifamily building with drains connected to the DWHR unit

Household Unit	N_{units}
Single-Family	1
Multi-Family	1 or Actual

SPCD = Showers Per Capita Per Day

= 0.6[1066]

365.25 = Days per year, on average.

SF = Water heating energy savings factor

= 0.466[1067]

3,412 = Conversion factor, 1 kWh equals 3,412 BTU

RE = Recovery efficiency of electric water heater:

= Actual or:

= 0.98[1068] for Electric Resistance

= 3.69[1069] for Electric HPWH

For example, for electric water heating, DHWR energy savings for a single family IQ home can be calculated as follows:

ΔkWh = ((101 – 50.7) * 8.33 * 2.35 * 7.8 * 2.76 * 1 * 0.6 * 365.25 * 0.466) / (3412 * 0.98)

= 647.4kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{\Delta kWh}{Hours} * CF$$

Where:

ΔkWh = calculated value from above.

Hours = Annual electric DHW recovery hours for showerhead use

[1065] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

[1066] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.

[1067] Codes and Standards Enhancement (CASE) Initiative, 2019 California Building Energy Efficiency Standards, Title 24, Part 6 Report. "Drain Water Heat Recovery - Final Report." July 2017, pg 17.

[1068] Review of AHRI database shows that electric water heaters have a recovery efficiency of 98%.

[1069] Review of AHRI database shows that Electric Heat Pump Water Heaters support this recovery efficiency. For the raw data, and calculations, please see AHRI_ RES Water Heaters 2025.xlsx.

$$= \frac{(GPM * Tshower{-}length) * Npersons * SPCD * 365.25\ ) * 0.726\ ^{1070}}{GPH}$$

= 286 for SF

= 234 for MF

Use Multifamily if: Building meets utility's definition for multifamily

GPH = Gallons per hour recovery of electric water heater calculated for 69.3°F temp rise (120-50.7), 98% recovery efficiency, and typical 4.5kW electric resistance storage tank.

= 26.1

CF = Coincidence Factor for electric load reduction

= 0.0278

For example, When a DHWR unit is installed in a Single Family home, summer coincident peak demand savings can be calculated as follows:

ΔkW = (647.4 / 286) * 0.0278

= 0.0629 kW

FOSSIL FUEL SAVINGS

For gas water heating, annual energy savings per unit are calculated through the following formula:

$$\Delta\text{Therms} = \frac{(\text{ShowerTemp} - \text{SupplyTemp}) * 8.33\frac{\text{BTU}}{\text{gal}\cdot^{\circ}\text{F}} * \text{GPM} * \text{T}_{\text{shower-length}} * \text{N}_{\text{persons}} * \text{N}_{\text{units}} * \text{SPCD} * 365.25\frac{\text{days}}{\text{yr}} * \text{SF}}{100{,}000\frac{\text{BTU}}{\text{therm}} * \text{RE}}$$

Where:

100,000 = Conversion factor, 1 therm equals 100,000 BTU

RE = efficiency of gas water heater: 79% for single family[1071] and 67% for multi family[1072]

For example, for gas water heating, DHWR energy savings for single family IQ home can be calculated as follows:

ΔTherms= ((101 – 50.7) * 8.33 * 2.35 * 7.8 * 2.76 * 1 * 0.6 * 365.25 * 0.466) / (100000 * 0.79)

= 27.4 therms

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

[1070] 72.6% is the proportion of hot 120F water mixed with 50.7F supply water to give 101F shower water.

[1071] DOE Final Rule discusses Recovery Efficiency with an average around 0.76 for Gas Fired Storage Water heaters and 0.78 for standard efficiency gas fired tankless water heaters up to 0.95 for the highest efficiency gas fired condensing tankless water heaters. These numbers represent the range of new units however, not the range of existing units in stock. Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 79%.

[1072] Water heating in Multifamily buildings is often provided by a larger central boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of 0.59 and the 0.75 for single family homes. An average efficiency of 0.67 is used for this analysis as a default for Multifamily buildings.

MEASURE CODE: RS-DHW-DWHR-V06-260101

REVIEW DEADLINE: 1/1/2029

5.4.12 Recirculating Pump Controls

DESCRIPTION

Demand control recirculation pumps seek to reduce inefficiency by combining control via temperature and demand inputs, whereby the controller will not activate the recirculation pump unless both (a) the recirculation loop return water has dropped below a prescribed temperature (e.g., 100°F) and (b) a Central Domestic Hot Water (CDHW) demand is sensed as water flow through the CDHW system.

This measure was developed to be applicable to the following program types: TOS, RF, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Re-circulating pump shall cycle on based on (a) the recirculation loop return water dropping below a prescribed temperature (e.g. 100°F) and (b) a CDHW demand is sensed as water flow through the CDHW system.

There are three alternative technologies that are considered in this characterization:

- Timer-based. This technology allows the user to program a schedule to perform recirculation during specific windows throughout the day.
- Aquastat-controlled. This type of control calls for recirculation when the water temperature at one point in the system falls below a certain pre-programmed setpoint.
- On-Demand. This technology senses the demand as water flow through the CDHW system. These types of system are most adequate on small central water heating systems.

DEFINITION OF BASELINE EQUIPMENT

The base case for this measure category is existing, uncontrolled recirculation pumps on either electric or gas-fired Central Domestic Hot Water systems (CDHW).

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The effective useful life is 15 years.[1073]

DEEMED MEASURE COST

The average cost of the demand controller circulation kit is $150 with an installation cost of $72 for a total measure cost of $222.[1074]

5.4.13 Auto-Diverting Tub Spout System

DESCRIPTION

This measure consists of replacing existing tub spouts and showerheads with an automatically diverting tub spout and showerhead system with a normally closed valve between the existing shower arm and showerhead. When the water temperature reaches a set point (generally 95°F), the thermostatic actuator will engage the anti-leak diverter in the tub spout. The water will divert to a showerhead with a normally closed valve that will prevent the hot water from going down the drain prior to the user entering the shower, thereby eliminating behavioral waste and tub spout leakage waste.

This measure was developed to be applicable to the following program types: RF, NC, DI, KITS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

There are two options under this measure: installing the full system and only installing the no-leak tub spout.

To qualify for the full system measure, the installed equipment must be an anti-leak, automatically diverting tub spout system with thermostatic actuator technology installed with an efficient showerhead equipped with a normally closed valve.

To qualify for the tub spout only measure, the installed equipment must be an anti-leak

DEFINITION OF BASELINE EQUIPMENT

The baseline condition for the full system is a residential tub spout with standard diverter, no thermostatic restrictor valve, and a standard showerhead rated at 2.0 GPM or greater.

The baseline condition for the tub spout only measure is a residential tub spout with a standard diverter.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 10 years.[1090]

DEEMED MEASURE COST

For the full tub spout with TSV and showerhead, the incremental cost of the measure should be the actual program cost (including labor if applicable), or $117.66[1091] plus $40[1092] labor if applicable.

If just the tub spout is installed (i.e., reuse existing showerhead), the incremental cost of the measure is $66.90 plus $20[1093] labor.

LOADSHAPE

Loadshape R03 - Residential Electric DHW

COINCIDENCE FACTOR

The coincidence factor for this measure is assumed to be 1.69%[1094]

[1090] Measure life is assumed to be consistent with 5.4.5 Low Flow Showerheads.
[1091] Average cost from online research at Lowes.com, HomeDepot.com, and Menards.com on 5/2/2024.
[1092] Estimate for contractor installation time. Based on 2X cost for thermostatic restrictor shower valve installation in TRM 5.4.8 (1X for showerhead / TSV install, 1X for tub spout).
[1093] Estimate for contractor installation time. Based on cost for thermostatic restrictor shower valve installation in TRM 5.4.8.
[1094] Calculated as follows: Assume 11% showers take place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.). There are 65 days in the summer peak period, so the percentage of total annual use in peak period is 0.11*65/365 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 223.7 = 4.38 hours of recovery during peak period, where 223.7 equals the average annual electric DHW recovery

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

For the full system:

ΔWater (gallons) = Showerhead Behavioral Waste + Tub Spout Behavioral Waste + Diverter Waste + Low Flow Showerhead Savings

For the no-leak tub spout:

ΔWater (gallons) = Tub Spout Behavioral Waste + Diverter Waste

Showerhead Behavioral Waste = $\%WUE_{SH}$ * GPM_base * L_showerdevice * SPCD * 365.25 * Household / SPH

Tub Spout Behavioral Waste = $\%WUE_{TS}$ * GPM_spout * L_showerdevice * SPCD * 365.25 * Household / SPH

Diverter Waste = DLR * L_base * SPCD * 365.25 * Household / SPH

Low Flow Showerhead Savings = (GPM_base * L_base - GPM_low * L_low) * SPCD * 365.25 * Household / SPH

$$\Delta kWh = \%ElectricDHW * \Delta Water\ (gallons) * EPG_electric * ISR$$

Where:

$\%WUE_{SH}$ = % of warm up events for showerhead

= 60%[1095]

$\%WUE_{TS}$ = % of warm up events for tub spout

= 40%[1096]

GPM_spout = Flow rate of the tub spout

= 5.0 GPM[1097]

GPM_base = Flow rate of the basecase showerhead, or actual if available

Program	GPM
Direct-install, device only	2.24[1098]
New Construction or direct install of device and low flow showerhead	Rated or actual flow of program-installed showerhead
Retrofit or TOS	2.35[1099]

hours for showerhead use. There are 260 hours in the peak period so the probability you will see savings during the peak period is 4.38/260 = 0.0169

[1095] Arkansas Technical Reference Manual, Version 9.1, pg. 162. https://apsc.arkansas.gov/programs-initiatives-activities/energy-efficiency/

[1096] Ibid.

[1097] Ibid.

[1098] Based on measurements conducted from June 2013 to January 2014 by Franklin Energy. Over 300 residential sites in the Chicago area were tested.

[1099] Representative value from sources 1, 2, 4, 5, 6 and 7 (See Source Table at end of measure section) adjusted slightly upward to account for program participation which is expected to target customers with existing higher flow devices rather than those with existing low flow devices.

GPM_low = As-used flow rate of the low-flow showerhead, which may, as a result of measurements of program evaulations deviate from rated flows, see table below[1100]:

L_showerdevice = Hot water waste time avoided due to thermostatic restrictor valve

= 0.89 minutes[1101]

SPCD = Showers Per Capita Per Day

= 0.6[1102]

365.25 = Days per year, on average

Household = Average number of people per household

Household Unit Type	Household[1103]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[1104]
Custom	Actual Occupancy or Number of Bedrooms[1105]		

Use Multifamily if: Building meets utility's definition for multifamily

SPH = Showerheads Per Household so that per-showerhead savings fractions can be Determined

Household Type	SPH
Single-Family	1.79[1106]
Multifamily	1.3[1107]
Household type unknown	1.64[1108]
Custom	Actual

Use Multifamily if: Building meets utility's definition for multifamily

DLR = Diverter leakage rate, gallons per minute

[1100] Note that actual values may be either a) program-specific minimum flow rate, or b) program-specific evaluation-based value of actual effective flow-rate due to increased duration or temperatures. The latter increases in likelihood as the rated flow drops and may become significant at or below rated flows of 1.5 GPM. The impact can be viewed as the inverse of the throttling described in the footnote for baseline flowrate.

[1101] Average of the following sources: ShowerStart LLC survey; "Identifying, Quantifying and Reducing Behavioral Waste in the Shower: Exploring the Savings Potential of ShowerStart", City of San Diego Water Department survey; "Water Conservation Program: ShowerStart Pilot Project White Paper", and PG&E Work Paper PGECODHW113.

[1110] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group. This study of 135 single and Multifamily homes in Michigan metered energy parameters for efficient showerhead and faucet aerators.

[1111] Ibid.

[1112] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1113] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

= 101°F [1114]

SupplyTemp = Assumed temperature of water entering house

= 50.7°F [1115]

RE_electric = Recovery efficiency of electric water heater

= 98% [1116]

3412 = Converts Btu to kWh (btu/kWh)

ISR = In service rate

Selection	ISR
Direct Install - Single Family	0.98[1117]
Direct Install – Multi Family	0.95[1118]
Efficiency Kits	To be determined through evaluation

Use Multifamily if: Building meets utility's definition for multifamily

Secondary kWh Savings for Water Supply and Wastewater Treatment

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh_{water} = \Delta Water\ (gallons) / 1{,}000{,}000 * E_{water\ total}$$

Where

$E_{water\ total}$ = IL Total Water Energy Factor (kWh/Million Gallons)

= 5,010[1119]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh/Hours * CF$$

Where:

ΔkWh = calculated value above. Note do not include the secondary savings in this calculation.

Hours = Annual electric DHW recovery hours for showerhead use

= ((GPM_base * L_base) * Household * SPCD * 365.25) * 0.726[1120] / GPH

GPH = Gallons per hour recovery of electric water heater calculated for 69.3°F temp rise (120-50.7),

[1114] Cadmus and Opinion Dynamics Showerhead and Faucet Aerator Meter Study Memorandum dated June 2013, directed to Michigan Evaluation Working Group.

[1115] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.

[1116] Electric water heaters have recovery efficiency of 98%.

[1117] Deemed values are from ComEd Energy Efficiency/ Demand Response Plan: Plan Year 2 (6/1/2009-5/31/2010) Evaluation Report: All Electric Single Family Home Energy Performance Tune-Up Program Table 3-8. Alternative ISRs may be developed for program delivery methods based on evaluation results.

[1118] Navigant, ComEd-Nicor Gas EPY4/GPY1 Multifamily Home Energy Savings Program Evaluation Report FINAL 2013-06-05

[1119] This factor includes 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

[1120] 72.6% is the proportion of hot 120F water mixed with 50.7F supply water to give 101F shower water.

98% recovery efficiency, and typical 4.5kW electric resistance storage tank.

= 26.1

CF = Coincidence Factor for electric load reduction

= 1.69%[1121]

FOSSIL FUEL SAVINGS

ΔTherms = %FossilDHW * Gallons Saved * EPG_gas * ISR

Where:

%FossilDHW = Percentage of DHW savings assumed to be fossil fuel

= 100% for Fossil Fuel

= 0% for Electric

= If unknown[1122], use the following table:

	Location				
Utility	**Single Family**	**Single Family Low Income**	**Multi Family**	**Multi Family Low Income**	**Unknown**
Ameren	80.3%	69.4%	36.7%	32.7%	68.6%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
People's Gas	97.9%	98.0%	98.3%	97.6%	97.8%
Northshore Gas	98.5%	98.2%	90.0%	97.6%	97.6%
Nicor Gas	92.4%	90.1%	85.6%	77.4%	90.0%
All DUs[1123]					**71%**

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

EPG_gas = Energy per gallon of Hot water supplied by gas

= (8.33 * 1.0 * (ShowerTemp - SupplyTemp)) / (RE_gas * 100,000)

= 0.0054 Therm/gal for SF homes

= 0.0063 Therm/gal for MF homes

RE_gas = Recovery efficiency of gas water heater

[1121] Calculated as follows: Assume 11% showers take place during peak hours (based on: Oreo et al, "The end uses of hot water in single family homes from flow trace analysis", 2001.). There are 65 days in the summer peak period, so the percentage of total annual use in peak period is 0.11*65/365 = 1.96%. The number of hours of recovery during peak periods is therefore assumed to be 1.96% * 223.7 = 4.38 hours of recovery during peak period, where 223.7 equals the average annual electric DHW recovery hours for showerhead use. There are 260 hours in the peak period so the probability you will see savings during the peak period is 4.38/260 = 0.0169

[1122] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1123] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

= 78% For individual water heater[1124]

= 67% For shared water heater[1125]

If unknown, use individual water heater value for single family, use shared water heater value for multifamily. Use multifamily if building meets utility's definition for multifamily.

100,000 = Converts Btus to Therms (btu/Therm)

Other variables as defined above.

MEASURE CODE: RS-HWE-ADTS-V02-260101

REVIEW DEADLINE: 1/1/2029

[1124] DOE Final Rule discusses Recovery Efficiency with an average around 0.76 for Gas Fired Storage Water heaters and 0.78 for standard efficiency gas fired tankless water heaters up to 0.95 for the highest efficiency gas fired condensing tankless water heaters. These numbers represent the range of new units however, not the range of existing units in stock. Review of AHRI Directory suggests range of recovery efficiency ratings for new Gas DHW units of 70-87%. Average of existing units is estimated at 78%.

[1125] Water heating in Multifamily buildings is often provided by a larger central boiler. This suggests that the average recovery efficiency is somewhere between a typical central boiler efficiency of 0.59 and the 0.75 for single family homes. An average efficiency of 0.67 is used for this analysis as a default for Multifamily buildings.

5.4.14 Residential Solar Water Heater

DESCRIPTION

A solar water heater provides water heating by collecting solar thermal energy and transferring it to the domestic water heating system to offset energy needed from electricity or fossil fuels. The solar water heater consists of a solar thermal collection panel which heats a heat transfer fluid, a heat exchanger tank inside the home where the heat is transferred from the heat transfer fluid to the domestic hot water supply, and a pump to move the heat transfer fluid. The system "pre-heats" the domestic water before it enters a standard water heater.

This measure characterizes the installation of a solar water heater with a new electric resistance water heater in a home.

This measure was developed to be applicable to the following program types: TOS, NC, RF.
If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be an ENERGY STAR[1126] certified solar water heater with a Solar Uniform Energy Factor (SUEF) of 3.00 or greater. The solar water heating collectors must meet the Solar Rating and Certification Corporation (SRCC™) OG-300 standard and be designed for a minimum 50% Solar Fraction.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is a new electric 50-gallon storage water heater meeting federal minimum efficiency standards. Assuming medium draw, the baseline efficiency is 0.9207 UEF.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 15 years[1127].

DEEMED MEASURE COST

For Time of Sale or New Construction the incremental installation cost (including labor) should be used. Defaults are provided below. Actual efficient costs can also be used although care should be taken as installation costs can vary significantly due to complexities of a particular site.

For retrofit costs, the actual full installation cost should be used (default provided below if unknown).

Baseline Installed Cost:

Item	Default Cost
Baseline Installed Cost	$882[1128]
New Solar Water Heater System	$6,757[1129]
Incremental Cost	$5,875

[1126] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification and corresponding Qualified Products List should continue to be used through the effective period of this TRM.
[1127] California eTRM, Measure ID SWWH032, in effect 1/1/2026. Based on DEER EUL tables.
[1128] Baseline ERWH equipment costs: Energy Solutions (2024). Heat Pump Water Heaters in the Northeast and Mid-Atlantic: Costs and Market Trends. Prepared for: Northeast States for Coordinated Air Use Management (NESCAUM) and The Ozone Transport Commission (OTC).). Installation labor cost from same study suggests $308, for a total of $882. Additionally, a review of 18 baseline ERWH models (5 different manufacturers; sizes ranging from 30-50 gallons) listed with online retailers (Home Depot, Lowes, Menards, and Ferguson Supply) available in IL established an average equipment cost of $575.
[1129] California eTRM, Measure ID SWWH032, in effect 1/1/2026.

LOADSHAPE

Loadshape R18 - Residential Heat Pump Water Heater

COINCIDENCE FACTOR

The summer Peak Coincidence Factor is assumed to be 12%.[1130]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((1/UEF_{Base} - 1/UEF_{Solar}) * GPD * Household * 365.25 * \gamma Water * (T_{OUT} - T_{IN}) * 1.0) / 3412$$

Where:

UEF_{BASE} = Uniform Energy Factor (efficiency) of standard water heater according to federal standards provided in table in baseline section and using the same draw pattern as the efficient equipment. For a deemed approach assume electric water heater:

= 0.9207 [1131]

UEF_{SOLAR} = Uniform Energy Factor (efficiency) equivalent of solar water heater.

Note: Do not use the Solar Uniform Energy Factor.

$$= \frac{UEF_{Backup}}{(1 - SF)}$$

SF = Solar Fraction of installed solar water heater

= Actual, provided on SRCC certification.

Use WI – Milwaukee value for Climate Zones 1 and 2, MO – St Louis for Climate Zones 4 and 5 and an average of the two for Climate Zone 3 or if location is unknown.

UEF_{backup} = Uniform Energy Factor of backup water heater.

= Actual. If unknown assume 0.9207 [1132]

GPD = Gallons Per Day of hot water use per person

= 45.5 gallons hot water per day per household/2.59 people per household [1133]

= 17.6

Household = Average number of people per household

[1130] Calculated from Figure 8 "Combined six-unit summer weekday average electrical demand" in FEMP study; 'Field Testing of Pre-Production Prototype Residential Heat Pump Water Heaters' as (average kW usage during peak period * hours in peak period) / [(annual kWh savings / FLH) * hours in peak period] = (0.1 kW * 5 hours) / [(2100 kWh (default assumptions) / 2533 hours) * 5 hours] = 0.12

[1131] Assuming a 50 gallon tank baseline at Medium Draw.

[1132] Assuming a 50 gallon tank baseline at Medium Draw.

[1133] Deoreo, B., and P. Mayer. Residential End Uses of Water Study Update. Forthcoming. ©2015 Water Research Foundation. Reprinted With Permission.

Household Unit Type	Household[1134]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[1135]
Custom	Actual Occupancy or Number of Bedrooms[1136]		

365.25 = Days per year

γWater = Specific weight of water

= 8.33 pounds per gallon

T_{OUT} = Tank temperature

= 125°F

T_{IN} = Incoming water temperature from well or municiple system

= 50.7°F [1137]

1.0 = Heat Capacity of water (1 Btu/lb*°F)

3412 = Conversion from Btu to kWh

For example, solar water heater with Solar Fraction of 0.56 with electric backup with UEF of 0.92 is installed in a single-family IQ home.

UEFsolar = 1/((1-0.56)/0.92)

= 2.1

ΔkWh $= ((1/UEF_{Base} - 1/UEF_{Solar}) * GPD * Household * 365.25 * \gamma Water * (T_{OUT} - T_{IN}) * 1.0) / 3412$

ΔkWh = ((1/0.9207 – 1/2.1) * 17.6 * 2.76 * 365.25 * 8.33 * (125-50.7) * 1)/3,412

= 1,963 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \Delta kWh / Hours * CF$$

Where:

ΔkWh = Electric savings (or increase) of measure

Hours = Full load hours of water heater

= 2,533 [1138]

[1134] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.
[1135] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.
[1136] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.
[1137] Table 4 in Chen, et. al., "Calculating Average Hot Water Mixes of Residential Plumbing Fixtures", June 2020, reports a value of 50.7°F for inlet water temperature for U.S. Census Division 3.
[1138] Full load hours assumption based on Efficiency Vermont analysis of Itron eShapes.

CF = Summer Peak Coincidence Factor for measure

= 0.12 [1139]

For example, solar water heater with Solar Fraction of 0.56 with electric backup with UEF of 0.92 is installed in a single-family IQ home.

ΔkW = 1,963/2533 * 0.12

= 0.0930 kW

5.5.4 Exterior Hardwired Compact Fluorescent Lamp (CFL) Fixture—Retired 12/31/2018, Removed in v8

5.5.5 Interior Hardwired Compact Fluorescent Lamp (CFL) Fixture—Retired 12/31/2018, Removed in v8

5.5.6 LED Specialty Lamps

DESCRIPTION

This measure describes savings from a variety of specialty LED lamp types (including globe, decorative and downlights). This characterization assumes that the LED lamp is installed in a residential location. Only Direct Install programs can continue to utilize this measure.

This measure was developed to be applicable to the following program types: DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure the installed equipment must be an ENERGY STAR[1140] LED lamp or fixture or equivalent to the most recent version of ENERGY STAR specifications. Note a new ENERGY STAR specification v2.1 becomes effective on 1/2/2017.

DEFINITION OF BASELINE EQUIPMENT

Specialty and Directional lamps were not included in the original definition of General Service Lamps in the Energy Independence and Security Act of 2007 (EISA). Therefore, the initial baseline is an incandescent / halogen lamp described in the table below.

A DOE Final Rule released on 1/19/2017 updated the EISA regulations to remove the exemption for these lamp types such that they become subject to the backstop provision defined within the original legislation. In September 2019 this decision was revoked in a new DOE Final Rule. However, in May 2022 DOE reversed this decision by issuing a Final rule for both the broadened General Service Lamp definition as well as the implementation of the 45 lumen per watt backstop. DOE stated that it will use its enforcement discretion to minimize impacts on the supply chain and effectively allow companies to continue the manufacture and import of noncompliant bulbs through the remainder of 2022, and allow retailers to continue selling them with limited enforcement until July 2023.

As of 1/1/2026, no savings are claimed for programs unless via direct install programs. Direct Install programs where it can be shown that the LED is replacing working inefficient lighting should continue to use the existing inefficient lighting as baseline and assume a measure life of 2 years.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The average rated life for Decorative lamps on the ENERGY STAR Qualified Products list (accessed 6/16/2020) is approximately 17,000 hours, and for Directional Lamps is approximately 25,000 hours.

However, the measure life is assumed to be two years for Direct Install, reflecting the expected remaining life of the baseline halogen/incandescent lamp.

DEEMED MEASURE COST

The actual cost of the bulb installed through Direct Install should be used. If the cost is unknown, assume the following:[1141]

Bulb Type	LED
Directional	$5.18
Decorative and Globe	$3.40

[1140] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[1141] Baseline and LED lamp costs for both directional and decorative and globe are based on field data collected by CLEAResult and provided by ComEd. See ComEd Pricing Projections 06302016.xlsx for analysis.

LOADSHAPE

Loadshape R06 - Residential Indoor Lighting

Loadshape R07 - Residential Outdoor Lighting

COINCIDENCE FACTOR

The summer peak coincidence factor is assumed to be 0.109 for residential and in-unit multifamily bulbs,[1142], 0.273 for exterior bulbs[1143] and 0.117 for unknown[1144]. Use Multifamily if the building meets the utility's definition for multifamily.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((WattsBase - WattsEE) / 1000) * ISR * Hours * WHFe$$

Where:

$Watts_{base}$ = Input wattage of the existing lamp. Reference the table below for default values.[1145]

$Watts_{EE}$ = Actual wattage of LED installed. If unknown, use default provided below.

[1142] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1143] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for specialty LEDs in exterior applications.

[1144] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1145] See file "LED Lamp Updates 2021-06-09" for details on Guidehouse lamp wattage calculations based on equivalent baseline wattage and LED wattage of available ENERGY STAR product.

Decorative Lamps – ENERGY STAR Minimum Luminous Efficacy = 65Lm/W for all lamps

Bulb Type	Minimum Lumens	Maximum Lumens	LED Wattage ($Watts_{EE}$)	Baseline ($Watts_{Base}$)	Delta Watts (WattsEE)
Omni-Directional 3-Way	1,100	1,999	14.7	100	85.3
	2,000	2,700	22.6	150	127.4
Globe (medium and intermediate bases less than 750 lumens)	310	349	3.0	25	22
	350	499	4.7	40	35.3
	500	574	5.7	60	54.3
	575	649	6.5	75	68.5
	650	1,000	8.2	100	91.8
Globe (candelabra bases less than 1050 lumens)	310	349	3.5	25	21.5
	350	499	4.4	40	35.6
	500	574	5.5	60	54.5
Decorative (Shapes B, BA, C, CA, DC, F, G, medium and intermediate bases less than 750 lumens)	310	499	4.3	40	35.7
	500	800	5.8	60	54.2
Decorative (Shapes B, BA, C, CA, DC, F, G, candelabra bases less than 1050 lumens)	310	499	4.2	40	35.8
	500	650	5.5	60	54.5
Decorative (Shape ST)	310	499	6.5	40	33.5
	500	999	8.8	60	51.2
	1000	1500	10.0	100	90.0
Decorative (Shape S)	310	340	2.25	25	22.8

Directional Lamps - ENERGY STAR Minimum Luminous Efficacy = 70Lm/W for <90 CRI lamps and 61 Lm/W for >=90CRI lamps.

For Directional R, BR, and ER lamp types:[1146]

[1146] From pg. 13 of the ENERGY STAR Specification for lamps v2.1

Bulb Type	Minimum Lumens	Maximum Lumens	LED Wattage ($Watts_{EE}$)	Baseline ($Watts_{Base}$)	Delta Watts (WattsEE)
Reflector lamp types with medium screw bases (PAR20, PAR30(S,L), PAR38, R40, etc.) w/ diameter >2.25" (*see exceptions below)	400	649	7.0	50	43
	650	899	10.7	75	64.3

	375	600	6.4	50	43.6
*BR30, BR40, or ER40	650	949	9.3	65	55.7
	950	1,099	12.7	75	62.3
	1,100	1,399	14.4	85	70.6
	1,400	1,600	16.6	100	83.4
	1,601	1,800	22.2	120	97.8
*R20	450	524	6.0	40	34.0
	525	750	7.1	45	37.9
*MR16	310	324	3.8	20.0	16.2
	325	369	4.8	25.0	20.2
	370	400	4.9	25.0	20.1

For PAR, MR, and MRX Lamps Types:

For these highly focused directional lamp types, it is necessary to have Center Beam Candle Power (CBCP) and beam angle measurements to accurately estimate the equivalent baseline wattage. The formula below is based on the ENERGY STAR Center Beam Candle Power tool.[1147] If CBCP and beam angle information are not available or if the equation below returns a negative value (or undefined), use the manufacturer's recommended baseline wattage equivalent.[1148]

$$\text{Wattsbase} = 375.1 - 4.355(D) - \sqrt{227{,}800 - 937.9(D) - 0.9903(D^2) - 1479(BA) - 12.02(D * BA) + 14.69(BA^2) - 16{,}720 * \ln(CBCP)}$$

Where:

D = Bulb diameter (e.g. for PAR20 D = 20)

BA = Beam angle

CBCP = Center beam candle power

[1147] See 'ESLampCenterBeamTool.xls'.

[1148] The ENERGY STAR Center Beam Candle Power tool does not accurately model baseline wattages for lamps with certain bulb characteristic combinations – specifically for lamps with very high CBCP.

The result of the equation above should be rounded DOWN to the nearest wattage established by ENERGY STAR:

Diameter	Permitted Wattages
16	20, 35, 40, 45, 50, 60, 75
20	50
30S	40, 45, 50, 60, 75
30L	50, 75
38	40, 45, 50, 55, 60, 65, 75, 85, 90, 100, 120, 150, 250

Additional EISA non-exempt bulb types:

Bulb Type	Minimum Lumens	Maximum Lumens	LED Wattage ($Watts_{EE}$)	Baseline ($Watts_{Base}$)	Delta Watts (WattsEE)
Dimmable Twist, Globe (less than 5" in diameter and > 749 lumens), candle (shapes B, BA, CA > 749 lumens), Candelabra Base Lamps (>1049 lumens), Intermediate Base Lamps (>749 lumens)	310	399	4.0	25	21.0
	400	749	6.6	29	22.4
	750	899	9.6	43	33.4
	900	1,399	13.1	53	39.9
	1,400	1,999	16.0	72	56.0

ISR = In Service Rate or the percentage of lamps rebated that get installed

Program	In Service Rate (ISR)
Direct Install	94.5%[1149]

Hours = Average hours of use per year

Installation Location	Annual hours of use (HOU)
Residential and In-Unit Multi Family	763[1150]
Exterior	2,475[1151]

[1149] Consistent with assumption for standard LEDs (in the absence of evidence that it should be different for this bulb type). Based upon average of Navigant low income single family direct install field work LED ISR and review of the PY2 and PY3 ComEd Direct Install program surveys. This value includes bulb failures in the 1st year to be consistent with the Commission approval of annualization of savings for first year savings claims. ComEd PY2 All Electric Single Family Home Energy Performance Tune-Up Program Evaluation, Navigant Consulting, December 21, 2010.

[1150] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1151] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. The IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide hours of use for specialty LEDs in exterior applications.

Installation Location	Annual hours of use (HOU)
Unknown	1,020[1152]

WHFe = Waste heat factor for energy to account for cooling savings from efficient lighting

Bulb Location	WHFe
Interior single family	1.06 [1153]
Multifamily in unit	1.04 [1154]
Exterior or uncooled location	1.0
Unknown location	1.046[1155]

Use Multifamily if: Building meets utility's definition for multifamily

For example, a 13W PAR20 LED is installed through a direct install program and installed in place of a 750 lumen PAR20 incandescent screw-in lamp with medium screw base, diameter >2.5" in a single family interior location:

ΔkWh = (((75 - 13) / 1,000) * 0.945 * 763 * 1.06

= 47.4 kWh

HEATING PENALTY

If electric heated home (if heating fuel is unknown assume gas, see Fossil Fuel section):

$$\Delta kWh^{1156} = -(((WattsBase - WattsEE) / 1{,}000) * ISR * Hours * HF) / \eta Heat$$

Where:

HF = Heating Factor or percentage of light savings that must be heated

= 49% for interior location [1157]

= 0% for exterior location

[1152] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1153] The value is estimated at 1.06 (calculated as 1 + (0.66*(0.27 / 2.8)). Based on cooling loads decreasing by 27% of the lighting savings (average result from REMRate modeling of several different configurations and IL locations of homes), assuming typical cooling system operating efficiency of 2.8 COP (starting from standard assumption of SEER2 13.4 central AC unit, converted to 11.4 EER2 using algorithm (-0.02 * $SEER^2$) + (1.12 * SEER) (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = EER2 * 0.85/3.412 = 2.8COP) and 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey)

[1154] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1155] Unknown is weighted average of interior v exterior (assuming 15% exterior specialty lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1156] Negative value because this is an increase in heating consumption due to the efficient lighting.

[1157] This means that heating loads increase by 49% of the lighting savings. This is based on the average result from REMRate modeling of several different configurations and IL locations of homes.

= 42% for unknown location [1158]

ηHeat = Efficiency in COP of Heating equipment

= Actual. If not available use: [1159]

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Heat Pump (if age unknown assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown[1160]	N/A	N/A	1.28

For example, a 13W PAR20 LED is purchased through a ComEd upstream program and installed in place of a 750 lumen PAR20 incandescent screw-in lamp with medium screw base, diameter >2.5" in a single family interior location with a 2016 heat pump:

ΔkWh = - (((75 - 13) / 1,000) * 0.945 * 763 * 0.49) / 2.04

= - 10.7 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ((WattsBase - WattsEE) / 1,000) * ISR * WHFd * CF

Where:

WHFd = Waste heat factor for demand to account for cooling savings from efficient lighting.

Bulb Location	WHFd
Interior single family	1.11[1161]
Multifamily in unit	1.07[1162]
Exterior or uncooled location	1.0

[1158] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1159] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note efficiency should include duct losses. Defaults provided assume 15% duct loss for heat pumps.

[1160] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[1161] The value is estimated at 1.11 (calculated as 1 + (0.66 * 0.466 / 2.8)). See footnote relating to WHFe for details. Note the 46.6% factor represents the average Residential cooling coincidence factor calculated by dividing average load during the peak hours divided by the maximum cooling load.

[1162] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

Bulb Location	WHFd
Unknown location	1.083[1163]

Use Multifamily if: Building meets utility's definition for multifamily

CF = Summer Peak Coincidence Factor for measure

= 0.109 for residential and in-unit multifamily bulbs[1164], 0.273 for exterior bulbs,[1165] and 0.117 for unknown.[1166]

Use Multifamily if: Building meets utility's definition for multifamily

Other factors as defined above

For example, a 13W PAR20 LED is installed through a direct install program and installed in place of a 750 lumen PAR20 incandescent screw-in lamp with medium screw base, diameter >2.5" in a single family interior location:

ΔkW = (((75 - 13) / 1,000) * 0.945 * 1.11* 0.109

= 0.0071 kW

FOSSIL FUEL SAVINGS

Heating penalty if Natural Gas heated home, or if heating fuel is unknown.

Δtherms = - (((WattsBase - WattsEE) / 1,000) * ISR * (1-Leakage) * Hours * HF * 0.03412) / ηHeat

Where:

HF = Heating factor, or percentage of lighting savings that must be replaced by heating system.

= 49% for interior[1167]

= 0% for exterior location

= 42% for unknown location[1168]

0.03412 = Converts kWh to Therms

ηHeat = Average heating system efficiency.

= 0.70 [1169]

[1163] Unknown is weighted average of interior v exterior (assuming 15% exterior specialty lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1164] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1165] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for specialty LEDs in exterior applications.

[1166] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1167] Average result from REMRate modeling of several different configurations and IL locations of homes

[1168] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1169] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois

Other factors as defined above

For example, a 13W PAR20 LED is purchased through a ComEd upstream program and installed in place of a 750 lumen PAR20 incandescent screw-in lamp with medium screw base, diameter >2.5" in single family interior location with gas heating at 70% total efficiency:

Δtherms = - (((75 - 13) / 1,000) * 0.945 * 763 * 0.49* 0.03412) / 0.70

= - 1.07 therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

MEASURE CODE: RS-LTG-LEDD-V18-260101

REVIEW DEADLINE: 1/1/2028

homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey) In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

5.5.7 LED Exit Signs

DESCRIPTION

This measure characterizes the savings associated with installing a Light Emitting Diode (LED) exit sign in place of a fluorescent or incandescent exit sign in a Multifamily building within unit (use 4.5.5 Commercial Exit Signs for multifamily common area exit signs). Light Emitting Diode exit signs have a string of very small, typically red or green, glowing LEDs arranged in a circle or oval. The LEDs may also be arranged in a line on the side, top or bottom of the exit sign. LED exit signs provide the best balance of safety, low maintenance, and very low energy usage compared to other exit sign technologies.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is assumed to be an exit sign illuminated by LEDs.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is assumed to be an existing fluorescent or incandescent model.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 5 years.[1170]

DEEMED MEASURE COST

The actual material and labor costs should be used if available. If actual costs are unavailable, assume a total installed cost of at $32.50.[1171]

LOADSHAPE

Loadshape C53 - Flat

COINCIDENCE FACTOR

The summer peak coincidence factor for this measure is assumed to be 100%.[1172]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((WattsBase - WattsEE) / 1000) * HOURS * WHF_e$$

Where:

WattsBase = Actual wattage if known, if unknown assume the following:

Baseline Type	$Watts_{Base}$
Incandescent	35W[1173]
CFL (dual sided)	14W[1174]

[1170] Estimate of remaining life of existing unit being replaced.
[1171] Price includes new exit sign/fixture and installation. LED exit sign cost/unit is $22.50 based on the NYSERDA Deemed Savings Database and review of LED exit signs available as of April 2023, and assuming I labor cost of 15 minutes @ $40/hr.
[1172] Assuming continuous operation of an LED exit sign, the Summer Peak Coincidence Factor is assumed to equal 1.0.
[1173] Based on review of available product.
[1174] Average CFL single sided (5W, 7W, 9W) from Appendix B 2013-14 Table of Standard Fixture Wattages.

Baseline Type	$Watts_{Base}$
CFL (single sided)	7W
Unknown	7W

WattsEE = Actual wattage if known, if single sided or unknown assume 2W, if dual sided assume 4W.[1175]

HOURS = Annual operating hours

= 8766

WHF_e = Waste heat factor for energy; accounts for cooling savings from efficient lighting.

= 1.04[1176]

Default if replacing incandescent fixture

ΔkWh = (35 – 2)/1000 * 8766 * 1.04

= 301 kWh

Default if replacing dual sided fluorescent fixture

ΔkWh = (14 – 4)/1000 * 8766 * 1.04

= 91 kWh

Default if replacing single sided fluorescent (or unknown) fixture

ΔkWh = (7 – 2)/1000 * 8766 * 1.04

= 46 kWh

HEATING PENALTY

If electric heated home (if heating fuel is unknown assume gas, see Fossil Fuel section):

ΔkWh[1177] = - (((WattsBase - WattsEE) / 1000) * Hours * HF) / ηHeat

Where:

HF = Heating Factor or percentage of light savings that must be heated

= 49%[1178]

ηHeat = Efficiency in COP of Heating equipment

= Actual. If not available use: [1179]

[1175] Average LED single sided (2W) from Appendix B 2013-14 Table of Standard Fixture Wattages.

[1176] The value is estimated at 1.04 (calculated as 1 + (0.45*(0.27 / 2.8)). Based on cooling loads decreasing by 27% of the lighting savings (average result from REMRate modeling of several different configurations and IL locations of homes), assuming typical cooling system operating efficiency of 3.1 COP (starting from standard assumption of SEER2 13.4 central AC unit, converted to 11.4 EER2 using algorithm (-0.02 * $SEER_2$) + (1.12 * SEER) (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = EER2 *0.85/3.412 = 2.8COP) and estimate of 45% of multi family buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1177] Negative value because this is an increase in heating consumption due to the efficient lighting.

[1178] This means that heating loads increase by 49% of the lighting savings. This is based on the average result from REMRate modeling of several different configurations and IL locations of homes.

[1179] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Heat Pump (if age unknown assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown[1180]	N/A	N/A	1.28

For example, a 2.0 COP (including duct loss) Heat Pump heated building:

If incandescent fixture: ΔkWh = -((35 – 2)/1000 * 8766 * 0.49) / 2
= -71 kWh

If unknown fixture ΔkWh = -((7 – 2)/1000 * 8766 * 0.49) / 2
= -10.7 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = ((WattsBase - WattsEE) / 1000) * WHF_d * CF$$

Where:

WHF_d = Waste heat factor for demand to account for cooling savings from efficient lighting. The cooling savings are only added to the summer peak savings.

=1.07[1181]

CF = Summer Peak Coincidence Factor for measure

= 1.0

Default if incandescent fixture

ΔkW = (35 – 2)/1000 * 1.07 * 1.0

= 0.035 kW

Default if dual sided fluorescent fixture

ΔkW = (14 – 4)/1000 * 1.07 * 1.0

= 0.0107 kW

Default if single sided fluorescent fixture

ΔkW = (7 – 2)/1000 * 1.07 * 1.0

Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note efficiency should include duct losses. Defaults provided assume 15% duct loss for heat pumps.

[1180] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[1181] The value is estimated at 1.11 (calculated as 1 + (0.45 * 0.466 / 2.8)). See footnote relating to WHFe for details. Note the 46.6% factor represents the average Residential cooling coincidence factor calculated by dividing average load during the peak hours divided by the maximum cooling load.

= 0.0054 kW

FOSSIL FUEL SAVINGS

Heating penalty if Natural Gas heated building, or if heating fuel is unknown.

ΔTherms = - (((WattsBase - WattsEE) / 1000) * Hours * HF * 0.03412) / ηHeat

Where:

HF = Heating factor, or percentage of lighting savings that must be replaced by heating system.

= 49% [1182]

0.03412 = Converts kWh to Therms

ηHeat = Average heating system efficiency.

= 0.70 [1183]

Other factors as defined above

Default if incandescent fixture

ΔTherms = - (((35 - 2) / 1000) * 8766 * 0.49* 0.03412) / 0.70

= -6.9 therms

Default if dual sided fluorescent fixture

ΔTherms = - (((14 - 4) / 1000) * 8766 * 0.49* 0.03412) / 0.70

= -2.1 therms

Default if single sided fluorescent fixture

ΔTherms = - (((7 - 2) / 1000) * 8766 * 0.49* 0.03412) / 0.70

= -1.05 therms

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

The annual O&M Cost Adjustment savings should be calculated using the following component costs and lifetimes.

	Baseline Measures	
Component	Cost	Life (yrs)
Lamp	$12.45[1184]	1.37 years[1185]

[1182] Average result from REMRate modeling of several different configurations and IL locations of homes

[1183] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey) In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

[1184] Consistent with assumption for a Standard CFL bulb ($2.45) with an estimated labor cost of $10 (assuming $40/hour and a task time of 15 minutes).

[1185] Assumes a lamp life of 12,000 hours and 8766 run hours 12000/8766 = 1.37 years.

MEASURE CODE: RS-LTG-LEDE-V05-260101

REVIEW DEADLINE: 1/1/2028

5.5.8 LED Screw Based Omnidirectional Bulbs

DESCRIPTION

This characterization provides savings assumptions for LED Screw Based Omnidirectional (e.g., A-Type lamps) lamps within the Income Qualified residential and multifamily sectors. This characterization assumes that the LED lamp is installed in a residential location. Only Direct Install programs can continue to utilize this measure.

This measure was developed to be applicable to the following program types: DI

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, new lamps must be ENERGY STAR[1186] labeled or equivalent to the most recent version of ENERGY STAR specifications. Note a new ENERGY STAR specification v2.1 became effective on 1/2/2017.

DEFINITION OF BASELINE EQUIPMENT

In 2012, Federal legislation stemming from the Energy Independence and Security Act of 2007 (EISA) will require all general-purpose light bulbs between 40 watts and 100 watts to have ~30% increased efficiency, essentially phasing out standard incandescent technology. In 2012, the 100 w lamp standards apply; in 2013 the 75 w lamp standards will apply, followed by restrictions on the 60 w and 40 w lamps in 2014. Since measures installed under this TRM all occur after 2014, baseline equipment are the values after EISA. These are shown in the baseline table below.

Additionally, an EISA backstop provision was included that would require replacement baseline lamps to meet an efficacy requirement of 45 lumens/watt or higher beginning on 1/1/2020. In December 2019, DOE issued a final determination for General Service Incandescent Lamps (GSILs), finding that this more stringent standard was not economically justified. However, in May 2022 DOE reversed this decision by issuing a Final rule for both the broadened General Service Lamp definition as well as the implementation of the 45 lumen per watt backstop. DOE stated that it will use its enforcement discretion to minimize impacts on the supply chain and effectively allow companies to continue the manufacture and import of noncompliant bulbs through the remainder of 2022, and allow retailers to continue selling them with limited enforcement until July 2023.

As of 1/1/2026, no savings are claimed for programs unless via direct install programs. Direct Install programs where it can be shown that the LED is replacing working inefficient lighting should continue to use the existing inefficient lighting as baseline and assume a measure life of 2 years.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The average rated life for Omnidirectional lamps on the ENERGY STAR Qualified Products list (accessed 6/16/2020) is approximately 20,000 hours.

However, the measure life is assumed to be two years for Direct Install, reflecting the expected remaining life of the baseline halogen/incandescent lamp.

DEEMED MEASURE COST

The actual LED lamp cost installed through Direct Install should be used. If cost is unknown, assume the $2.70 per lamp[1187]

LOADSHAPE

Loadshape R06 – Residential Indoor Lighting

[1186] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[1187] Baseline and LED lamp costs are based on field data collected by CLEAResult and provided by ComEd. See ComEd Pricing Projections 06302016.xlsx for analysis.

Loadshape R07 – Residential Outdoor Lighting

COINCIDENCE FACTOR

The summer peak coincidence factor is assumed to be 0.128 for Residential and in-unit Multi Family bulbs,[1188] 0.273 for exterior bulbs,[1189] and 0.135 for unknown,[1190]

Use Multifamily if: Building meets utility's definition for multifamily.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((Watts_{base}-Watts_{EE})/1000) * ISR * Hours * WHF_e$$

Where:

$Watts_{base}$ = Input wattage of the existing lamp. Reference the "LED New and Baseline Assumptions" table for default values.

$Watts_{EE}$ = Actual wattage of LED installed. If unknown, use default provided below:[1191]

LED New and Baseline Assumptions Table

Minimum Lumens	Maximum Lumens	LED Wattage (WattsEE)	Baseline (WattsBase)	Delta Watts (WattsEE)
310	399	4.0	25	21.0
400	749	6.6	29	22.4
750	899	9.6	43	33.4
900	1,399	13.1	53	39.9
1,400	1,999	16.0	72	56.0
2,000	2,999	21.8	150	128.2
3,000	3,299	28.9	200	171.1

ISR = In Service Rate, the percentage of lamps rebated that are actually in service.

Program	In Service Rate (ISR)
Direct Install	94.5%[1192]

[1188] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1189] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.

[1190] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1191] See file "LED Lamp Updates 2021-06-09" for details on Guidehouse lamp wattage calculations based on equivalent baseline wattage and LED wattage of available ENERGY STAR product.

[1192] Based upon average of Navigant low income single family direct install field work LED ISR and Standard CFL assumption in the absence of better data, and is based upon review of the PY2 and PY3 ComEd Direct Install program surveys. This value includes bulb failures in the 1st year to be consistent with the Commission approval of annualization of savings for first year savings claims. ComEd PY2 All Electric Single Family Home Energy Performance Tune-Up Program Evaluation, Navigant Consulting, December 21, 2010.

Hours = Average hours of use per year

Installation Location	Hours
Residential and in-unit Multi Family	1,089[1193]
Exterior	2,475[1194]
Unknown	1,159[1195]

WHFe = Waste heat factor for energy to account for cooling energy savings from efficient lighting

Bulb Location	WHFe
Interior single family	1.06 [1196]
Multifamily in unit	1.04 [1197]
Exterior or uncooled location	1.0
Unknown location	1.051[1198]

For example, an 8W LED lamp, 450 lumens, is installed in the interior of a home through Direct Install.

ΔkWh = ((29.0 - 8) /1000) * 0.945 * 1,089 * 1.06

= 22.9 kWh

HEATING PENALTY

If electric heated home (if heating fuel is unknown assume gas, see Fossil Fuel section):

$$\Delta kWh^{1199} = -(((WattsBase - WattsEE) / 1000) * ISR * Hours * HF) / \eta Heat$$

Where:

HF = Heating Factor or percentage of light savings that must be heated

[1193] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1194] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. The IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide hours of use for screw-based omnidirectional LEDs in exterior applications.

[1195] Based on a weighted average of hours of use in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1196] The value is estimated at 1.06 (calculated as 1 + (0.66*(0.27 / 2.8)). Based on cooling loads decreasing by 27% of the lighting savings (average result from REMRate modeling of several different configurations and IL locations of homes), assuming typical cooling system operating efficiency of 2.8 COP (starting from standard assumption of SEER2 13.4 central AC unit, converted to 11.4 EER2 using algorithm (-0.02 * $SEER^2$) + (1.12 * SEER) (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = EER2 * 0.85/3.412 = 2.8COP) and 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey)

[1197] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from “Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009” which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1198] Unknown is weighted average of interior v exterior (assuming 5% exterior lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1199] Negative value because this is an increase in heating consumption due to the efficient lighting.

= 49% for interior[1200]

= 0% for exterior or unheated location

= 42% for unknown location[1201]

ηHeat = Efficiency in COP of Heating equipment

= actual. If not available use:[1202]

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Heat Pump (if age unknown assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown[1203]	N/A	N/A	1.28

For example: using the same 8 W LED that is installed in home with 2.0 COP Heat Pump (including duct loss) through a Direct Install program:

ΔkWh = - (((29 - 8) / 1000) * 0.945 * 1,089 * 0.42) / 2.0

= - 4.5 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ((WattsBase - WattsEE) / 1000) * ISR * WHFd * CF

Where:

WHFd = Waste heat factor for demand to account for cooling savings from efficient lighting.

Bulb Location	WHFd
Interior single family	1.11[1204]

[1200] This means that heating loads increase by 49% of the lighting savings. This is based on the average result from REMRate modeling of several different configurations and IL locations of homes.

[1201] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1202] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note efficiency should include duct losses. Defaults provided assume 15% duct loss for heat pumps.

[1203] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[1204] The value is estimated at 1.11 (calculated as 1 + (0.66 * 0.466 / 2.8)). See footnote relating to WHFe for details. Note the 46.6% factor represents the average Residential cooling coincidence factor calculated by dividing average load during the peak hours divided by the maximum cooling load.

Bulb Location	WHFd
Multifamily in unit	1.07[1205]
Exterior or uncooled location	1.0
Unknown location	1.093[1206]

CF = Summer Peak Coincidence Factor for measure.

Bulb Location	CF
Interior	0.128[1207]
Exterior	0.273[1208]
Unknown	0.135[1209]

Other factors as defined above

For example: for the same 8 W LED that is installed in a single family interior location through a Direct Install program:

ΔkW = ((29 - 8) / 1000) * 0.945 * 1.11 * 0.128

= 0.0028 kW

FOSSIL FUEL SAVINGS

Heating penalty if Natural Gas heated home, or if heating fuel is unknown.

ΔTherms = - (((WattsBase - WattsEE) / 1000) * ISR * Hours * HF * 0.03412) / ηHeat

Where:

HF = Heating factor, or percentage of lighting savings that must be replaced by heating system.

= 49% for interior[1210]

= 0% for exterior location

= 42% for unknown location[1211]

[1205] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1206] Unknown is weighted average of interior v exterior (assuming 5% exterior lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1207] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1208] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.

[1209] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1210] Average result from REMRate modeling of several different configurations and IL locations of homes

[1211] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

0.03412	= Converts kWh to Therms
ηHeat	= Average heating system efficiency.
	= 0.70 [1212]

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

MEASURE CODE: RS-LTG-LEDA-V17-260101

REVIEW DEADLINE: 1/1/2028

[1212] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey) In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

5.5.9 LED Fixtures

DESCRIPTION

This characterization provides savings assumptions for LED Fixtures and is broken into five five fixture types formerly listed by ENERGY STAR: Indoor Fixtures (including track lighting, wall-wash, sconces, ceiling and fan lights), Task and Downlight Under Cabinet Fixtures, including LED desk lamps (linear under cabinet fixtures are exempt from EISA and so can be found in measure 5.5.13), Outdoor Fixtures (including flood light, hanging lights, security/path lights, outdoor porch lights), and Downlight Fixtures.

Only Direct Install programs can continue to utilize this measure.

This measure was developed to be applicable to the following program types: DI.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, new LED fixtures, except downlights must be equivalent to the ENERGY STAR Luminaries Specification v2.2 (effective 8/15/2019)[1213]. Downlights must be ENERGY STAR listed and certified according to ENERGY STAR Downlights specification v1.0 (effective 11/1/2023). Specifications are as follows:

Fixture Category	Lumens/Watt
Indoor	65
Downlight Task and Under Cabinet	50
Outdoor	60
Downlight	55

DEFINITION OF BASELINE EQUIPMENT

The baseline condition for this measure is assumed to be an average of EISA-equivalent wattages for ENERGY STAR-qualified products. Most of the lamp types in this measure are considered specialty so the baseline adjustments are consistent with the 5.5.6 LED Specialty Lamps.

Specialty and Directional lamps were not included in the original definition of General Service Lamps in the Energy Independence and Security Act of 2007 (EISA). Therefore, the initial baseline is an incandescent / halogen lamp described in the tables below.

A DOE Final Rule released on 1/19/2017 updated the EISA regulations to remove the exemption for these lamp types such that they become subject to the backstop provision defined within the original legislation. In September 2019 this decision was revoked in a DOE Final Rule. However, in May 2022 DOE reversed this decision by issuing a Final rule for both the broadened General Service Lamp definition as well as the implementation of the 45 lumen per watt backstop. DOE stated that it will use its enforcement discretion to minimize impacts on the supply chain and effectively allow companies to continue the manufacture and import of noncompliant bulbs through the remainder of 2022, and allow retailers to continue selling them with limited enforcement until July 2023.

As of 1/1/2026, no savings are claimed unless via direct install programs. Direct Install programs where it can be shown that the LED is replacing working inefficient lighting should continue to use the existing inefficient lighting as baseline and assume a measure life of 2 years.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The lifetime of a fixture is a function of its rated life and average hours of use. The rated life is 47,000 hours for

[1213] ENERGY STAR support for LED lamps and LED fixtures, except downlights, is discontinued as of 12/31/2024. The referenced specifications are the most recent ones in effect and should be used as guidelines when qualifying lamps and fixtures.

indoor and downlight, 45,000 for downlight task and under cabinet, and 49,000 for outdoor fixtures.[1214]

However, the measure life is assumed to be two years for Direct Install, reflecting the expected remaining life of the baseline halogen/incandescent lamp.

DEEMED MEASURE COST

The actual cost of the fixture installed through Direct Install should be used.

LOADSHAPE

Loadshape R06 - Residential Indoor Lighting

Loadshape R07 - Residential Outdoor Lighting

COINCIDENCE FACTOR

The summer peak coincidence factor is assumed to be 0.119 for residential and in-unit multifamily fixtures,[1215] 0.273 for exterior fixtures,[1216] and 0.127 for unknown.[1217]

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((Watts_{base}-Watts_{EE})/1000) * ISR * Hours * WHF_e$$

Where:

$Watts_{Base}$ = Input wattage of the existing fixture. Reference table below for default values for each fixture category;[1218].

$Watts_{EE}$ = Actual wattage of LED fixture installed - If unknown, use default provided below:[1219]

Fixture Category	$Watts_{Base}$	$Watts_{EE}$
Indoor	88.5	22.4
Downlight Task and Under Cabinet	45.2	11.6
Outdoor	79.6	18.3
Downlight	72.8	20.3

ISR = In Service Rate, the percentage of units rebated that are actually in service

= 1.0[1220]

[1214] Average rated lives are based on the average rated lives of fixtures available on the ENERGY STAR qualifying list as of 2/26/2018.

[1215] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs. Average of values for standard and specialty bulbs.

[1216] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.

[1217] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1218] See "Analysis" tab within file Residential LED Fixtures_Analysis_June 2018.xlsx for baseline calculations.

[1219] Average of ENERGY STAR product category watts for products at or above the version 2.1 efficacy specification

[1220] ISR recommendation for fixtures in the Dunsky Energy Consulting, Livingston Energy Innovations and Opinion Dynamics Corporation; NEEP Emerging Technology Research Report, p 6-22.

Hours = Average hours of use per year

Fixture Category	Hours
Indoor and Downlight	926[1221]
Task/Under Cabinet	730[1222]
Outdoor	2,475[1223]

WHFe = Waste heat factor for energy to account for cooling energy savings from efficient lighting

Bulb Location	WHFe
Interior single family	1.06 [1224]
Multifamily in unit	1.04 [1225]
Exterior or uncooled location	1.0
Unknown location	1.051[1226]

For example, an indoor LED fixture is installed through a Direct Install program:

ΔkWh = ((88.5 – 22.4) /1000) * 1.0 * 926 * 1.06

= 64.9 kWh

HEATING PENALTY

If electric heated home (if heating fuel is unknown assume gas, see Fossil Fuel section):

ΔkWh[1227] = - (((WattsBase - WattsEE) / 1000) * ISR * Hours * HF) / ηHeat

Where:

HF = Heating Factor or percentage of light savings that must be heated

[1221] Assuming 365.25 days/year and average of recommended values for standard LED lamps (2.98) and specialty LED lamps (2.09) in interior locations from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs

[1222] Task/under cabinet hours of use are estimated at 2 hours per day.

[1223] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. The IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide hours of use for screw-based omnidirectional LEDs in exterior applications.

[1224] The value is estimated at 1.06 (calculated as 1 + (0.66*(0.27 / 2.8)). Based on cooling loads decreasing by 27% of the lighting savings (average result from REMRate modeling of several different configurations and IL locations of homes), assuming typical cooling system operating efficiency of 2.8 COP (starting from standard assumption of SEER2 13.4 central AC unit, converted to 11.4 EER2 using algorithm (-0.02 * $SEER^2$) + (1.12 * SEER) (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = EER2 * 0.85/3.412 = 2.8COP) and 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey)

[1225] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from “Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009” which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1226] Unknown is weighted average of interior v exterior (assuming 5% exterior lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1227] Negative value because this is an increase in heating consumption due to the efficient lighting.

= 49%[1228] for interior location

= 0% for exterior or unheated location

= 42%[1229] for unknown location

ηHeat = Efficiency in COP of Heating equipment

= actual. If not available use:[1230]

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Heat Pump (if age unknown assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown[1231]	N/A	N/A	1.28

For example, using the same indoor LED fixture that is installed in home with 2.0 COP Heat Pump (including duct loss) through a Direct Install Program:

ΔkWh = - (((88.5 – 22.4) / 1000) * 1.0 * 926 * 0.49) / 2.0

= - 15.0 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ((WattsBase - WattsEE) / 1 000) * ISR * WHFd * CF

Where:

WHFd = Waste heat factor for demand to account for cooling savings from efficient lighting.

Bulb Location	WHFd
Interior single family	1.11[1232]

[1228] This means that heating loads increase by 49% of the lighting savings. This is based on the average result from REMRate modeling of several different configurations and IL locations of homes.

[1229] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1230] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note efficiency should include duct losses. Defaults provided assume 15% duct loss for heat pumps.

[1231] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[1232] The value is estimated at 1.11 (calculated as 1 + (0.66 * 0.466 / 2.8)). See footnote relating to WHFe for details. Note the 46.6% factor represents the average Residential cooling coincidence factor calculated by dividing average load during the peak hours divided by the maximum cooling load.

Bulb Location	WHFd
Multifamily in unit	1.07[1233]
Exterior or uncooled location	1.0
Unknown location	1.093[1234]

CF = Summer Peak Coincidence Factor for measure.

Bulb Location	CF
Interior	0.119[1235]
Exterior	0.273[1236]
Unknown	0.127[1237]

Other factors as defined above

For example, for the same indoor LED fixture that is installed in a single family interior location through a direct install program, the demand savings are:

ΔkW = ((88.5 – 22.4) / 1000) * 1.0 * 1.11 * 0.119

= 0.0087 kW

FOSSIL FUEL SAVINGS

Heating penalty if Natural Gas heated home, or if heating fuel is unknown.

ΔTherms = - (((WattsBase - WattsEE) / 1000) * ISR * Hours * HF * 0.03412) / ηHeat

Where:

HF = Heating factor, or percentage of lighting savings that must be replaced by heating system.

= 49% for interior or unknown location[1238]

= 0% for exterior location

= 42% for unknown location[1239]

[1233] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1234] Unknown is weighted average of interior v exterior (assuming 5% exterior lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1235] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs. Average of values for standard and specialty bulbs.

[1236] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.

[1237] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

MEASURE CODE: RS-LTG-LDFX-V08-260101

REVIEW DEADLINE: 1/1/2028

[1240] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey) In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

5.5.10 Holiday String Lighting

DESCRIPTION

This measure categorizes the savings from customers handing in incandescent string lighting typically used during the holidays and receiving equivalent LED string lighting. LED bulbs on string lights can consume up to 98% less power when compared to incandescent bulbs. Besides less energy to operate, LED string lighting offers many other advantages over incandescent: longer bulb life, a higher brightness, less heat buildup making them safer especially when used indoors on live trees, and better durability since they use a plastic covering over the diode instead of a glass bulb.[1241]

This measure applies to mini, C7, and C9 bulb shape types used in residential locations. Description of the bulb types of string lighting are listed below: [1242, 1243]

Mini: About 1/4" wide x 5/8" high with a shape described as a miniature candle with a pointed tip. The mini is the most common type of string light today and shares about 80% of the market. They have a female-to-male push type base.

C7: Approximately 1" wide x 1-1/2" high with a shape described as a strawberry. The C7 (and C9) are thought of as more "old fashioned" or traditional since they were the first types of string lighting used for decorative purposes. The C7 shares about 7% of the market and has a screw-in E12 candelabra base.

C9: Similar in shape to the C7, the C9 is slightly larger at 1-1/4" wide x 2-1/2" high. The C9 shares about 5% of the market and has a screw-in E17 intermediate base.

A third variant of the "C" bulb exists, which is called C6. However, due to lack of availability of the C6 incandescent from retailers, it is assumed the market has already adopted the LED as the baseline for this bulb shape type and should not be claimed for utility program savings.

The implementation strategy for this measure is only geared towards residential customers. Furthermore, the deemed hours of operation are sourced on residential only. As such, the proposed deemed split of 100% Residential and 0% Commercial assumptions should be used.

This measure was developed to be applicable to the following program types: EREP. To ensure that the baseline is appropriate, the measure is limited to an exchange event where the customer has to turn in a string of inefficient lighting.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, new string lights must be LED and one of the eligible bulb shape categories listed in this measure (mini, C7, C9).

Some manufacturers offer integrated "smart" control of new LED strings; however, these are not included in this measure.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is the existing incandescent mini, C7, or C9 string lighting turned in during an exchange event.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The rated lifespan of LED bulbs for string lighting is in the range of 20,000 to 100,000 hours of use. However, the measure lifetime is capped at 7 years due to wear on bulbs and string from weather, sunlight, and annual installation

[1241] See 'Christmas Lights Buying Guide – Hayneedle'.
[1242] See 'Christmas Lights Buying Guide – Hayneedle'.
[1243] See 'Christmas Lights Guide Visual'.

and storage.[1244]

DEEMED MEASURE COST

Where possible, the actual, full cost of new LED string lighting should be used. If unavailable, assume the following costs.

Bulb Type	Measure Cost[1245]
Mini	$15.38
C7	$21.42
C9	$17.28

Loadshape

Loadshape R16; Residential Holiday String Lighting

COINCIDENCE FACTOR

Due to the seasonal nature and evening operation of holiday string lights, there is no expected reduction in a utility's peak demand.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((Watts_{base}-Watts_{EE})/1000) * ISR * (1-Leakage) * Hours * WHF_e$$

Where:

$Watts_{base}$ = Total wattage of the existing incandescent string lights = Bulb Wattage * # Bulbs; see table below for baseline bulb wattage assumptions

$Watts_{EE}$ = Actual total wattage of the new LED string lights = Bulb Wattage * # Bulbs. If unknown, assume total wattage of new LED string lights = Bulb Wattage * # Bulbs; see table below for LED bulb wattage assumptions

Where:

Bulb Wattage = Reference the "Bulb Wattage Assumptions" table below.

Bulb Wattage Assumptions[1246]

Type	Incandescent Bulb (Watts)	LED Bulb (Watts)
Mini	0.40	0.07
C7	5.00	0.48
C9	7.00	2.00

Bulbs = Actual quantity of bulbs on the string. If baseline is unknown, assume same as the new string.

ISR = In Service Rate, or percentage of string lights that get installed. Derive from program

[1244] LED string lighting lifetime from https://www.christmasdesigners.com/blog/how-long-do-led-christmas-lights-really-last/'How Long Do LED Christmas Lights Really Last_Christmas Designers'

[1245] See file Holiday Lights Research and Calcs_2018.xlsx for CLEAResult research on holiday string lighting costs.

[1246] Average wattages from PGE "Cost of holiday lights", published December 2021, and PA PUC Feb 2021.

evaluation analysis, otherwise assume 100%.

Leakage = Adjustment to account for the percentage of program string lights that move out (and in, if deemed appropriate) of the Utility Jurisdiction.

= For an exchange event, assume 0% if customer is required to be a utility customer. If not, determine leakage rate through evaluation. If customer is not required to be utility customer and if leakage is not determined through evaluation, use the deemed leakage rates LED omnidirectional bulbs sold through Upstream (TOS) programs:[1247]

ComEd: 1.6%

Ameren: 13.1%

Hours = Average hours of use per year

= 210 hours[1248]

WHFe = Waste heat factor for energy to account for cooling energy savings from efficient lighting, assumed value of 1.0 since operation of string lights (if indoors) does not coincide with cooling season and there are no interactive effects for outdoor string lights.

For example, a customer replaces a 50-bulb mini incandescent string with a 50-bulb mini LED string through exchange event:

ΔkWh = ((0.40 * 50) – (0.07 * 50))/1000) * 1.00 * (1 - 0) * 210 * 1.0

= 3.5 kWh

HEATING PENALTY

If electric heated home (if heating fuel is unknown assume gas, see Fossil Fuel section):

$$\Delta kWh^{1249} = -(((WattsBase - WattsEE)/1000) * ISR * (1-Leakage) * Hours * HF) / \eta Heat$$

Where:

HF = Heating Factor or percentage of light savings that must be heated
= 49% for interior or unknown location[1250]
= 0% for exterior or unheated location

ηHeat = Efficiency in COP of Heating equipment

= actual. If not available, use:[1251]

System Type	Age of Equipment	HSPF2 Estimate	COPheat (COP Estimate) = (HSPF2/3.412) * 0.85
Heat Pump	Before 2006	5.8	1.44

[1247] Leakage rate is based upon review of PY8-CY2018 evaluations from ComEd and PY8 for Ameren.

[1248] Based on typical holiday lighting hours of use (6 hours per day, 7 days per week for 5 weeks) from California Municipal Utilities Association "TRM 205 LED Holiday Lights."

[1249] Negative value because this is an increase in heating consumption due to the efficient lighting.

[1250] This means that heating loads increase by 49% of the lighting savings. This is based on the average result from REMRate modeling of several different configurations and IL locations of homes.

[1251] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note efficiency should include duct losses. Defaults provided assume 15% duct loss for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate	COPheat (COP Estimate) = (HSPF2/3.412) * 0.85
(if age unknown assume 2006-2014)	After 2006-2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1
Unknown[1252]	N/A	N/A	1.28

For example, using the same 50-bulb mini LED string that is installed in home with 2.0 COP Heat Pump (including duct loss):

ΔkWh = - ((((0.40 * 50) – (0.07 * 50))/1000) * 1.00 * (1 - 0) * 210 * 0.49) / 2.0

= - 0.8 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

Heating penalty if installed in a natural gas heated home, or if heating fuel is unknown.

ΔTherms = - (((WattsBase - WattsEE)/1000) * ISR * (1-Leakage) * Hours * HF * 0.03412) / ηHeat

Where:

HF = Heating factor, or percentage of lighting savings that must be replaced by heating system.

= 49% for interior or unknown location [1253]

= 0% for exterior location

0.03412 = Converts kWh to Therms

ηHeat = Actual heating system efficiency

= 70% [1254]

[1252] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[1253] Average result from REMRate modeling of several different configurations and IL locations of homes.

[1254] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey). In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in

For example, using the same 50-bulb mini LED string that is installed in a single family interior location with gas heating at 70% total efficiency:

$$\Delta therms = - ((((0.40 * 50) – (0.07 * 50))/1000) * 1.00 * (1 - 0) * 210 * 0.49 * 0.03412) / 0.70$$
$$= - 0.08 \text{ therms}$$

MEASURE CODE: RS-LTG-LEDH-V05-260101

REVIEW DEADLINE: 1/1/2028

the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

5.5.11 LED Nightlights

DESCRIPTION

This measure describes savings from LED nightlights. This characterization assumes that the LED nightlight is installed in a residential location.

This measure was developed to be applicable to the following program types: TOS, NC.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

For this characterization to apply, the high-efficiency equipment must be a qualified LED nightlight.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is assumed to be an incandescent/halogen nightlight.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated useful life of the is estimated is 8 years.[1255]

DEEMED MEASURE COST

Where possible, the actual cost should be used and compared to the baseline cost. If the incremental cost is unknown, assume the following:[1256]

Bulb Type	Year	Incandescent	LED	Incremental Cost
Nightlights	All	$2.84	$6.19	$3.35

LOADSHAPE

Loadshape R07 - Residential Outdoor Lighting

COINCIDENCE FACTOR

Demand savings is assumed to be zero for this measure.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((WattsBase - WattsEE) / 1000) * ISR * (1-Leakage) * Hours * WHFe$$

Where:

$Watts_{base}$ = Actual wattage if known, if unknown, assume 7W.[1257]

$Watts_{EE}$ = Actual wattage of LED purchased / installed.

ISR = In Service Rate or the percentage of nightlights rebated that get installed

[1255] Southern California Edison Company, "LED, Electroluminescent & Fluorescent Night Lights", Work Paper WPSCRELG0029 Rev. 1, February 2009, p. 2. and p.3.
[1256] Average cost data provided in Stanley Mertz, "LED Nightlights Energy Efficiency Retail products programs", March 2018.
[1257] Based on Stanley Mertz, "LED Nightlights Energy Efficiency Retail products programs", March 2018.

Program	In Service Rate (ISR) [1258]
Retail (Time of Sale)	97.6%[1259]
Direct Install	96.9%[1260]
School Kits	83.3%[1261]

Leakage = Adjustment to account for the percentage of program bulbs that move out (and in if deemed appropriate)[1262] of the Utility Jurisdiction.

KITS programs = Determined through evaluation

Upstream (TOS) Lighting programs = Use deemed assumptions below:[1263]

ComEd: 2.0%

Ameren: 13.1%

Hours = Average hours of use per year

= 4,380[1264]

WHFe = Waste heat factor for energy to account for cooling savings from efficient lighting

Bulb Location	WHFe
Interior single family	1.06 [1265]

[1258] In Service Rates now represent the lifetime In Service Rates with the second and third year installations discounted by the Real Discount Rate of 2.0%. Lifetime ISR assumptions for efficiency kits are based upon comparing with CFL Distribution First year ISR and multiplying by the CFL Distribution Final ISR value, capped at 95%, and second and third year estimates based on same proportion of future installs. For all other programs The 98% Lifetime ISR assumption is based upon the standard CFL measure in the absence of any better reference. This value is based upon review of two evaluations:
'Nexus Market Research, RLW Analytics and GDS Associates study; "New England Residential Lighting Markdown Impact Evaluation, January 20, 2009' and 'KEMA Inc, Feb 2010, Final Evaluation Report:, Upstream Lighting Program, Volume 1.' This implies that only 2% of bulbs purchased are never installed. The second and third year installations are based upon Ameren analysis of the Californian KEMA study showing that 54% of future installs occur in year 2 and 46% in year 3.

[1259] 1st year in service rate is based upon analysis of ComEd PY8, PY9 and CY2018 and Ameren PY8 intercept data (see 'RES Lighting ISR_2019.xlsx' for more information).

[1260] Consistent with assumption for standard CFLs (in the absence of evidence that it should be different for this bulb type). Based upon review of the PY2 and PY3 ComEd Direct Install program surveys. This value includes bulb failures in the 1st year to be consistent with the Commission approval of annualization of savings for first year savings claims. ComEd PY2 All Electric Single Family Home Energy Performance Tune-Up Program Evaluation, Navigant Consulting, December 21, 2010.

[1261] 1st year ISR for school kits based on ComEd PY9 data for the Elementary Energy Education program.

[1262] Leakage in is only appropriate to credit to IL utility program savings if it is reasonably expected that the IL utility program marketing efforts played an important role in influencing customer to purchase the light bulbs. Furthermore, consideration that such customers might be free riders should be addressed. If leakage in is assessed, efforts should be made to ensure no double counting of savings occurs if the evaluation is estimating both leakage in and spillover savings of light bulbs.

[1263] Leakage rate is based upon review of PY7-9 evaluations from ComEd and PY5,6 and 8 for Ameren (see for more information).

[1264] Assumes nightlight is operating 12 hours per day, consistent with the 2016 Pennsylvania TRM.

[1265] The value is estimated at 1.06 (calculated as 1 + (0.66*(0.27 / 2.8)). Based on cooling loads decreasing by 27% of the lighting savings (average result from REMRate modeling of several different configurations and IL locations of homes), assuming typical cooling system operating efficiency of 2.8 COP (starting from standard assumption of SEER2 13.4 central AC unit, converted to 11.4 EER2 using algorithm (-0.02 * $SEER^2$) + (1.12 * SEER) (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = EER2 * 0.85/3.412 = 2.8COP) and 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey)

Bulb Location	WHFe
Multifamily in unit	1.04 [1266]
Unknown location	1.054[1267]

For example, a 0.3W LED nightlight is direct installed in single family interior location within ComEd territory:

ΔkWh = ((7 – 0.3) / 1000) * 0.969 * (1 – 0) * 4380 * 1.06

= 30.1 kWh

HEATING PENALTY

If electric heated home (if heating fuel is unknown assume gas, see Fossil Fuel section):

$$\Delta kWh^{1268} = -(((WattsBase - WattsEE) / 1000) * ISR * Hours * HF) / \eta Heat$$

Where:=(

HF = Heating Factor or percentage of light savings that must be heated

= 49% for interior[1269]

ηHeat = Efficiency in COP of Heating equipment

= Actual. If not available use: [1270]

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Heat Pump (if age unknown assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown[1271]	N/A	N/A	1.28

[1266] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1267] Unknown is based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1268] Negative value because this is an increase in heating consumption due to the efficient lighting.

[1269] This means that heating loads increase by 49% of the lighting savings. This is based on the average result from REMRate modeling of several different configurations and IL locations of homes.

[1270] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note efficiency should include duct losses. Defaults provided assume 15% duct loss for heat pumps.

[1271] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

For example, a 0.3W LED nightlight is direct installed in single family interior location with a 2016 heat pump:

ΔkWh = - (((7 – 0.3) / 1000) * 0.969 * (1-0) * 4380 * 0.49) / 2.04

= - 6.83 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = ((WattsBase - WattsEE) / 1 000) * ISR * (1-Leakage) * WHFd * CF

Where:

WHFd = Waste heat factor for demand to account for cooling savings from efficient lighting.

Bulb Location	WHFd
Interior single family or unknown location	1.11[1272]
Multifamily in unit	1.07[1273]
Unknown location	1.098[1274]

CF = Summer Peak Coincidence Factor for measure.

= 0

FOSSIL FUEL SAVINGS

Heating penalty if Natural Gas heated home, or if heating fuel is unknown.

Δtherms = - (((WattsBase - WattsEE) / 1000) * ISR * Hours * HF * 0.03412) / ηHeat

Where:

HF = Heating factor, or percentage of lighting savings that must be replaced by heating system.

= 49% for interior[1275]

0.03412 = Converts kWh to Therms

ηHeat = Average heating system efficiency

= 0.70 [1276]

Other factors as defined above

[1272] The value is estimated at 1.11 (calculated as 1 + (0.66 * 0.466 / 2.8)). See footnote relating to WHFe for details. Note the 46.6% factor represents the average Residential cooling coincidence factor calculated by dividing average load during the peak hours divided by the maximum cooling load.

[1273] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1274] Unknown is based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1275] Average result from REMRate modeling of several different configurations and IL locations of homes

[1276] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey) In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

For example, a 0.3W LED nightlight is direct installed in single family interior location with gas heating at 70% total efficiency:

Δtherms = - (((7 – 0.3) / 1000) * 0.969 * (1-0) * 4380 * 0.49* 0.03412) / 0.70

= - 0.68 therms

5.5.12 Connected LED Lamps

DESCRIPTION

Many home devices in the market have become integrated with smart technology in recent years. Home devices able to connect to Wifi or a mobile network allow the user to control the device over the internet. This measure defines the savings associated with connected lighting. Connected LEDs allow for remote user control through a smart device, such as smart phone, tablet, or smart speaker. The standard LED provides light in one shade at one lumen level and color temperature. Connected LEDs have options integrated that allow for customizable color, color temperature, and lumen output. The Connected LED can also be turned on and off with a set schedule or controlled remotely. Savings from this measure come from both reduced hours of operation and dimming.

This measure was developed to be applicable to the following program types: TOS, NC

DEFINITION OF EFFICIENT EQUIPMENT

For this characterization to apply, the efficient condition must be LED lighting that is controlled by a smart device. The savings for this measure are the estimated incremental control savings compared to a non-connected efficient lamp. Some connected LEDs come with hubs for managing their operations. Connected LEDs with hubs do not qualify for this savings characterization, as the energy use by the hub cancels out the savings attributed to the connectivity of the lamp.

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is the efficient LED without the connected capabilities.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The deemed measure life is 8.1 years for exterior application.[1277] For all other applications, lifetimes are capped at 10 years.[1278]

DEEMED MEASURE COST

The incremental cost can be assumed to be $20, the difference between the average cost of the baseline non-connected LED and the average cost of the connected LED.[1279]

LOADSHAPE

Loadshape R06 – Residential Indoor Lighting

Loadshape R07 – Residential Outdoor Lighting

COINCIDENCE FACTOR

The summer peak coincidence factor is provided below:

Bulb Location	CF
Interior Omnidirectional	0.128[1280]
Interior Specialty	0.109[1281]

[1277] The average rated life for Omnidirectional lamps on the ENERGY STAR Qualified Products list (accessed 6/16/2020) is approximately 20,000 hours. 20000/2475 (exterior hours of use) = 8.1 years.

[1278] Based on recommendation in the Dunsky Energy Consulting, Livingston Energy Innovations and Opinion Dynamics Corporation; NEEP Emerging Technology Research Report, p 6-18.

[1279] Estimate based on review of available product and estimates provided in King J., ACEEE, "Energy Impacts of Smart Home Technologies", April 2018.

[1280] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1281] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

Bulb Location	CF
Exterior	0.273[1282]
Unknown Omnidirectional	0.135[1283]
Unknown Specialty	0.117[1284]

Use Multifamily if: Building meets utility's definition for multifamily.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((\frac{WattsEE}{1000} * HOURS * SVGe * WHFe) - StandbykWh) * ISR * (1 - Leakage)$$

Where:

WattsEE = Actual wattage of LED. If unknown, then use defaults in 5.5.6 LED Specialty Lamps or 5.5.8 LED Screw Based Omnidirectional Bulbs.

HOURS = Average hours of use per year

Installation Location	Hours
Residential and in-unit Multi Family Omnidirectional	1,089[1285]
Residential and in-unit Multi Family Specialty	763[1286]
Exterior	2,475[1287]
Unknown	1,159[1288]
Unknown Specialty	1,020[1289]

SVGe = Percentage of annual lighting energy saved by lighting control; determined on a site-specific basis or using default below

[1282] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.

[1283] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1284] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1285] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1286] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1287] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. The IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide hours of use for screw-based omnidirectional LEDs in exterior applications.

[1288] Based on a weighted average of hours of use in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1289] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

= 0.37[1290]

ISR = In Service Rate, the percentage of lamps rebated that are actually in service.

Program		Weighted Average 1st year In Service Rate (ISR) [1291]
Retail (Time of Sale)		97.4%
Direct Install		94.5%
Efficiency Kits	LED Distribution	82.3%
	School Kits	83.3%
	Direct Mail Kits	91.2%
	Direct Mail Kits, Income Qualified	94.2%
	Community Distributed Kits	94.8%
Food Bank / Pantry Distribution		97.5%

Leakage = Adjustment to account for the percentage of program bulbs that move out (and in if deemed appropriate)[1292] of the Utility Jurisdiction.

KITS programs = Determined through evaluation

Upstream (TOS) Lighting programs = Use deemed assumptions below:[1293]

ComEd: 0.8%

Ameren: 13.1%

All other programs = 0

WHFe = Waste heat factor for energy to account for cooling savings

Bulb Location	WHFe
Interior single family	1.06 [1294]

[1290] Based on Lockheed Martin, 'Home Energy Management System/Cmart Lighting Pilot for National Grid's Massachusetts and Rhode Island Residential Energy Efficiency Programs', Final Report, March 18, 2019. The study found the energy consumption of the LED to be 11.5/1000 * 1200 hours = 13.8kWh. Savings from the smart lamp included both geo fencing (96% of studied homes providing 5.1kWh of savings) and in-room occupancy (3% of studied homes providing 6.6kWh of savings), for a total savings of 5.1kWh (0.96*5.1 + 0.03*6.6). As a percentage of the LED consumption this is 5.1/13.8 = 37%.

[1291] ISRs are consistent with the LED Screw Based Standard Lamp measure, however since 2nd and 3rd year savings for this measure are so minimal, for ease of implementation the 3 year installs are discounted using the real discount rate (2.0%) a single assumption.

[1292] Leakage in is only appropriate to credit to IL utility program savings if it is reasonably expected that the IL utility program marketing efforts played an important role in influencing customer to purchase the light bulbs. Furthermore, consideration that such customers might be free riders should be addressed. If leakage in is assessed, efforts should be made to ensure no double counting of savings occurs if the evaluation is estimating both leakage in and spillover savings of light bulbs.

[1293] Leakage rate is based upon review of PY8-CY2018 evaluations from ComEd and PY8 for Ameren.

[1294] The value is estimated at 1.06 (calculated as 1 + (0.66*(0.27 / 2.8)). Based on cooling loads decreasing by 27% of the lighting savings (average result from REMRate modeling of several different configurations and IL locations of homes), assuming typical cooling system operating efficiency of 2.8 COP (starting from standard assumption of SEER2 13.4 central AC unit, converted to 11.4 EER2 using algorithm (-0.02 * $SEER^2$) + (1.12 * SEER) (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = EER2 *0.85/3.412 = 2.8COP) and 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey)

Bulb Location	WHFe
Multifamily in unit	1.04 [1295]
Exterior or uncooled location	1.0
Unknown location Omnidirectional	1.051[1296]
Unknown location Specialty	1.046[1297]

StandbykWh = Standby power draw of the controlled lamp. Use actual value from manufacturer specification. If not known then assume:

= 0.63 kWh[1298]

For example, a 9W Connected LED is purchased through a ComEd upstream program.

$\Delta kWh_{1st\ year\ installs}$ = (((9/1000) * 1,089 * 0.37 * 1.051) – 0.63) * 0.9 * (1 – 0.008)

= 2.84 kWh

HEATING PENALTY

If electric heated home (if heating fuel is unknown assume gas, see Fossil Fuel section):

$$\Delta kWh^{1299} = -\frac{((WattsEE * Hours * SVGe) - StandbykWh) * ISR * (1 - Leakage) * HF}{1000 * \eta Heat}$$

Where:

HF = Heating Factor or percentage of light savings that must be heated

= 49% for interior[1300]

ηHeat = Efficiency in COP of Heating equipment

= Actual. If not available use: [1301]

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Heat Pump	Before 2006	5.8	1.44

[1295] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1296] Unknown is weighted average of interior v exterior (assuming 5% exterior lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1297] Unknown is weighted average of interior v exterior (assuming 15% exterior specialty lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1298] Based on Lockheed Martin, 'Home Energy Management System/Cmart Lighting Pilot for National Grid's Massachusetts and Rhode Island Residential Energy Efficiency Programs', Final Report, March 18, 2019.

[1299] Negative value because this is an increase in heating consumption due to the efficient lighting.

[1300] This means that heating loads increase by 49% of the lighting savings. This is based on the average result from REMRate modeling of several different configurations and IL locations of homes.

[1301] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note efficiency should include duct losses. Defaults provided assume 15% duct loss for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
(if age unknown assume 2006-2014)	After 2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown[1302]	N/A	N/A	1.28

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kWh = (\frac{WattsEE}{1000}) * SVGd * WHFd * ISR * (1 - Leakage) * CF$$

Where:

SVGd = Percentage of annual lighting demand saved by lighting control; determined on a site-specific basis or using default below

= 0.37[1303]

WHFd = Waste heat factor for demand to account for cooling savings from efficient lighting.

Bulb Location	WHFd
Interior single family	1.11[1304]
Multifamily in unit	1.07[1305]
Exterior or uncooled location	1.0
Unknown location Omnidirectional	1.093[1306]
Unknown location Specialty	1.083[1307]

CF = Summer Peak Coincidence Factor for measure.

Bulb Location	CF
Interior Omnidirectional	0.128[1308]

[1302] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[1303] Assumed equal to SVGe.

[1304] The value is estimated at 1.11 (calculated as 1 + (0.66 * 0.466 / 2.8)). See footnote relating to WHFe for details. Note the 46.6% factor represents the average Residential cooling coincidence factor calculated by dividing average load during the peak hours divided by the maximum cooling load.

[1305] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1306] Unknown is weighted average of interior v exterior (assuming 5% exterior lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1307] Unknown is weighted average of interior v exterior (assuming 15% exterior specialty lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1308] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

Bulb Location	CF
Interior Specialty	0.109[1309]
Exterior	0.273[1310]
Unknown Omnidirectional	0.135[1311]
Unknown Specialty	0.117[1312]

For example, a 9W Connected LED is purchased through a ComEd upstream program.

$\Delta kW_{1st\ year\ installs}$ = (((9/1000) * 0.37 * 1.093)) * 0.9 * (1 – 0.008)

= 0.0032 kW

FOSSIL FUEL SAVINGS

Heating penalty if Natural Gas heated home, or if heating fuel is unknown.

$$\Delta Therms = -\frac{((WattsEE * Hours * SVGe) - StandbykWh) * ISR * (1 - Leakage) * HF * 0.03412}{1000 * \eta Heat}$$

Where:

HF = Heating factor, or percentage of lighting savings that must be replaced by heating system.

= 49% for interior[1313]

0.03412 = Converts kWh to Therms

ηHeat = Average heating system efficiency

= 0.70 [1314]

Other factors as defined above

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

NA

[1309] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1310] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.

[1311] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1312] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1313] Average result from REMRate modeling of several different configurations and IL locations of homes

[1314] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey) In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

DEEMED O&M COST ADJUSTMENT CALCULATION

NA

MEASURE CODE: RS-LTG-LEDC-V06-260101

REVIEW DEADLINE: 1/1/2029

5.5.13 EISA Exempt LED Lighting

DESCRIPTION

This characterization provides savings assumptions for LED lamps and fixture types that are exempt from the EISA legislation. This characterization assumes that the LED lamp is installed in a residential location. Where the implementation strategy does not allow for the installation location to be known (e.g., an upstream retail program) a deemed split of 97% Residential and 3% Commercial assumptions should be used.[1315]

This measure was developed to be applicable to the following program types: TOS, NC, EREP, DI, KITS.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, new lamps must be ENERGY STAR[1316] labeled or equivalent to the most recent version of ENERGY STAR specifications or be listed on the Design Lights Consortium Qualifying Product List. Note a new ENERGY STAR specification v2.1 became effective on 1/2/2017.

DEFINITION OF BASELINE EQUIPMENT

This measure is only for lamp and fixture types that are exempt from EISA, including lamps with an initial lumen output of less than 310 lumens, with initial lumen output greater than 3,300 lumens, and Task/Undercabinet Fixtures with a linear fluorescent baseline.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The average rated life for lamps on the ENERGY STAR Qualified Products list (accessed 6/16/2020) is approximately 20,000 hours for omnidirectional lamps, 17,000 hours for decorative lamps and 25,000 for directional lamps. The deemed measure life is 8 years for exterior omnidirectional lamps and 6.9 years for exterior decorative lamps and lifetimes are capped at 10 years for other applications.[1317] For early replacement measures, if replacing a halogen or incandescent bulb, the remaining life is assumed to be 333 hours. For CFL's, the remaining life is 3,333 hours.[1318]

The rated life of linear task and under cabinet fixtures is 45,000 hours[1319] and for T-LEDS is 50,000 hours. However, all fixture lifetimes are capped at 15 years.[1320]

DEEMED MEASURE COST

The price of LED lamps is falling quickly. Where possible, the actual LED lamp cost should be used and compared to the baseline cost provided below. If the incremental cost is unknown, assume the following:

Type	Incremental Cost
Omni-directional A-Lamps	$1.45[1321]

[1315] RES v C&I split is based on a weighted (by sales volume) average of ComEd PY8, PY9 and CY2018 and Ameren PY8 in store intercept survey results. See 'RESvCI Split_2019.xlsx'.

[1316] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[1317] Based on recommendation in the Dunsky Energy Consulting, Livingston Energy Innovations and Opinion Dynamics Corporation; NEEP Emerging Technology Research Report, p 6-18.

[1318] Representing a third of the expected lamp lifetime.

[1319] Average rated lives are based on the average rated lives of fixtures available on the ENERGY STAR qualifying list as of 2/26/2018.

[1320] Based on recommendation in the Dunsky Energy Consulting, Livingston Energy Innovations and Opinion Dynamics Corporation; NEEP Emerging Technology Research Report, p 6-18.

[1321] Baseline and LED lamp costs are based on field data collected by CLEAResult and provided by ComEd. See ComEd Pricing Projections 06302016.xlsx for analysis.

Type	Incremental Cost
Decorative	$1.66
Directional	$1.65
Linear Task/Under Cabinet	$18[1322]
T-LEDs	$13[1323]

LOADSHAPE

Loadshape R06 – Residential Indoor Lighting

Loadshape R07 – Residential Outdoor Lighting

COINCIDENCE FACTOR

The summer peak coincidence factor is assumed to be 0.128 for Residential and in-unit Multi Family bulbs,[1324] 0.273 for exterior bulbs,[1325] and 0.135 for unknown,[1326]

Use Multifamily if: Building meets utility's definition for multifamily.

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = ((Watts_{base}-Watts_{EE})/1000) * ISR * (1-Leakage) * Hours * WHF_e$$

Where:

$Watts_{base}$ = Input wattage of the existing or baseline system. Reference the "LED New and Baseline Assumptions" table for default values.

$Watts_{EE}$ = Actual wattage of LED purchased / installed. If unknown, use default provided below:[1327]

LED New and Baseline Assumptions Table

[1322] Incremental costs for task/under cabinet and downlight fixtures are from the 2018 Michigan Energy Measures Database.
[1323] Consistent with measure 4.5.4 LED Bulbs and Fixtures in Volume 2.
[1324] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.
[1325] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.
[1326]Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.
[1327] See file "LED Lamp Updates 2021-06-09" for details on Guidehouse lamp wattage calculations based on equivalent baseline wattage and LED wattage of available ENERGY STAR product.

Type		Minimum Lumens	Maximum Lumens	LED Wattage (WattsEE)	Baseline (WattsBase)	Delta Watts
A-Lamps		120	309	4.0	25	21.0
		3,300	3,999	28.9	200	171.1
		4,000	5,000	35.7	300	264.3
Decorative	Globe (medium and intermediate bases less than 750 lumens)	150	309	3.0	25	22
	Globe (candelabra bases less than 1050 lumens)	150	309	3.5	25	21.5
	Decorative (Shapes B, BA, C, CA, DC, F, G, medium and intermediate bases less than 750 lumens)	160	299	2.6	25	22.4
		300	309	4.3	40	35.7
	Decorative (Shapes B, BA, C, CA, DC, F, G, candelabra bases less than 1050 lumens)	120	159	1.5	15	13.5
		160	299	2.7	25	22.3
		300	309	4.2	40	35.8
	Decorative (Shape ST)	250	309	6.5	40	33.5
	Decorative (Shape S)	50	75	1.0	11	10.0
		100	120	1.2	15	13.8
		120	309	2.25	25	22.8
Directional	Reflector lamp types with medium screw bases (PAR20, PAR30(S,L), PAR38, R40, etc.) w/ diameter >2.25"	3,300	4,200	27.3	250	222.7
	Reflector lamp types with medium screw bases (PAR16, R14, R16, etc.) w/ diameter <2.25" (*see exceptions below)	280	309	4.6	35	30.4
	*MR16	250	309	3.8	20.0	16.2
Linear Task/Under Cabinet[1328]		0	2999	11.6	29.1	17.5
		3000	4499	28.0	57	29.0
		4500	5999	39.2	84.5	56.5
		6000	7499	49.9	120	70.1
		7500		90.6	180	89.4
T-LEDs		0	1,199	8.9	15	6.1
		1,200	2,399	15.8	28.2	12.4
		2,400		22.9	41.8	18.9

ISR = In Service Rate, the percentage of lamps rebated that are actually in service.

[1328] See "Linear Strip LED Fixture Lumen Buckets.xlsx" for details on the calculation of Linear Task/Under Cabinet values.

Program		In Service Rate (ISR)[1329]
Retail (Time of Sale)		97.4%[1330]
Direct Install		94.5%[1331]
Virtual Assessment followed by Unverified Self-Install		97.5%[1332]
Efficiency Kits[1333]	LED Distribution[1334]	82.3%
	School Kits[1335]	83.3%
	Direct Mail Kits[1336]	91.2%
	Direct Mail Kits, Income Qualified[1337]	60%
	Community Distributed Kits[1338]	94.8%
Food Bank / Pantry Distribution[1339]		97.5%[1340]

Leakage = Adjustment to account for the percentage of program bulbs that move out (and in if deemed appropriate)[1341] of the Utility Jurisdiction.

[1329] In Service Rates now represent the lifetime In Service Rates with the second and third year installations discounted by the Real Discount Rate of 2.0%. Lifetime ISR assumptions for efficiency kits are based upon comparing with CFL Distribution First year ISR and multiplying by the CFL Distribution Final ISR value, capped at 95%, and second and third year estimates based on same proportion of future installs. For all other programs Tthe 98% Lifetime ISR assumption is based upon the standard CFL measure in the absence of any better reference. This value is based upon review of two evaluations:
'Nexus Market Research, RLW Analytics and GDS Associates study; "New England Residential Lighting Markdown Impact Evaluation, January 20, 2009' and 'KEMA Inc, Feb 2010, Final Evaluation Report:, Upstream Lighting Program, Volume 1.' This implies that only 2% of bulbs purchased are never installed. The second and third year installations are based upon Ameren analysis of the Californian KEMA study showing that 54% of future installs occur in year 2 and 46% in year 3.

[1330] 1st year in service rate is based upon analysis of ComEd PY8, PY9 and CY2018 and Ameren PY8 intercept data (see 'RES Lighting ISR_2019.xlsx' for more information).

[1331] Based upon average of Navigant low income single family direct install field work LED ISR and Standard CFL assumption in the absence of better data, and is based upon review of the PY2 and PY3 ComEd Direct Install program surveys. This value includes bulb failures in the 1st year to be consistent with the Commission approval of annualization of savings for first year savings claims. ComEd PY2 All Electric Single Family Home Energy Performance Tune-Up Program Evaluation, Navigant Consulting, December 21, 2010.

[1332] An equal weighted average of Direct Install and Direct Mail Kit ISRs. Interest and applicability of measures confirmed through virtual assessment.

[1333] In Service Rates provided are for the bulb within a kit only. Given the significant differences in program design and the level of education provided through Efficiency Kits programs, the evaluators should apply the ISR estimated through evaluations (either past evaluations or the current program year evaluation) of the specific Efficiency Kits program. In cases where program-specific evaluation results for an ISR are unavailable, the default ISR values for Efficiency Kits provide may be used.

[1334] Free bulbs provided without request, with little or no education. Consistent with Standard CFL assumptions.

[1335] 1st year ISR for school kits based on ComEd PY9 data for the Elementary Energy Education program. Final ISR assumptions are based upon comparing with CFL Distribution First year ISR and multiplying by the CFL Distribution Final ISR value, and second and third year estimates based on same proportion of future installs.

[1336] Opt-in program to receive kits via mail, with little or no education. Consistent with Standard CFL assumptions.

[1337] Research from 2021 Ameren Illinois Income Qualified participant survey (customer self-report), available on IL SAG website: https://ilsag.s3.amazonaws.com/AIC-Income-Qualified-Initiative-Participant-Survey-Results-Memo-FINAL-2022-02-01.pdf

[1338] Kits distributed in a community setting, targeted to income qualified communities. Research from 2018 Ameren Illinois Income Qualified participant survey.

[1339] Free bulbs provided through local food banks and food pantries.

[1340] 1st year ISR is determined based on online surveys conducted for ComEd CY2018 Food Bank LED Distribution program. See 'CY2018 ComEd Foodbank LED Dist Survey Results_Navigant'.

[1341] Leakage in is only appropriate to credit to IL utility program savings if it is reasonably expected that the IL utility program marketing efforts played an important role in influencing customer to purchase the light bulbs. Furthermore, consideration that such customers might be free riders should be addressed. If leakage in is assessed, efforts should be made to ensure no double counting of savings occurs if the evaluation is estimating both leakage in and spillover savings of light bulbs.

KITS programs = Determined through evaluation

Upstream (TOS) Lighting programs = Use deemed assumptions below:[1342]

ComEd: 0.8%

Ameren: 13.1%

All other programs = 0

Hours = Average hours of use per year

Type	Installation Location	Hours
Omnidirectional A-Lamps	Residential and in-unit Multi Family	1,089[1343]
	Exterior	2,475[1344]
	Unknown	1,159[1345]
Decorative and Directional Lamps	Residential and In-Unit Multi Family	763[1346]
	Exterior	2,475[1347]
	Unknown	1,020[1348]
Linear Task/Under Cabinet	All	730[1349]
T-LEDs	All	730[1350]

WHFe = Waste heat factor for energy to account for cooling energy savings from efficient lighting

Bulb Location	WHFe
Interior single family	1.06 [1351]
Multifamily in unit	1.04 [1352]

[1342] Leakage rate is based upon review of PY8-CY2018 evaluations from ComEd and PY8 for Ameren.

[1343] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1344] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. The IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide hours of use for screw-based omnidirectional LEDs in exterior applications.

[1345] Based on a weighted average of hours of use in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1346] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1347] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. The IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide hours of use for specialty LEDs in exterior applications.

[1348] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1349] Linear Task/Under Cabinet hours of use are estimated at 2 hours per day.

[1350] Consistent with Linear Task/Under Cabinet assumption.

[1351] The value is estimated at 1.06 (calculated as 1 + (0.66*(0.27 / 2.8)). Based on cooling loads decreasing by 27% of the lighting savings (average result from REMRate modeling of several different configurations and IL locations of homes), assuming typical cooling system operating efficiency of 2.8 COP (starting from standard assumption of SEER2 13.4 central AC unit, converted to 11.4 EER2 using algorithm (-0.02 * $SEER^2$) + (1.12 * SEER) (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = EER2 * 0.85/3.412 = 2.8COP) and 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey)

[1352] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from “Table

Bulb Location	WHFe
Exterior or uncooled location	1.0
Unknown location	1.051[1353]

For example, an 4W LED lamp, 300 lumens, is installed in the interior of a home. The customer purchased the lamp through a ComEd upstream program:

ΔkWh = ((25.0 - 4) /1000) * 0.784 * (1 - 0.008) * 1,089 * 1.06

= 18.9 kWh

HEATING PENALTY

If electric heated home (if heating fuel is unknown assume gas, see Fossil Fuel section):

$$\Delta kWh^{1354} = -(((WattsBase - WattsEE) / 1000) * ISR * (1-Leakage) * Hours * HF) / \eta Heat$$

Where:

HF = Heating Factor or percentage of light savings that must be heated

= 49% for interior[1355]

= 0% for exterior or unheated location

= 42% for unknown location[1356]

ηHeat = Efficiency in COP of Heating equipment

= actual. If not available use:[1357]

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Heat Pump (if age unknown assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00

HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1353] Unknown is weighted average of interior v exterior (assuming 5% exterior lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1354] Negative value because this is an increase in heating consumption due to the efficient lighting.

[1355] This means that heating loads increase by 49% of the lighting savings. This is based on the average result from REMRate modeling of several different configurations and IL locations of homes.

[1356] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1357] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note efficiency should include duct losses. Defaults provided assume 15% duct loss for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Unknown[1358]	N/A	N/A	1.28

For example: using the same 4W LED that is installed in home with 2.0 COP Heat Pump (including duct loss) through a ComEd upstream program:

$\Delta kWh_{1st\ year}$ = - (((25 - 4) / 1000) * 0.784 * (1-0.008) * 1,089 * 0.42) / 2.0

= - 3.7 kWh

Second and third year install savings should be calculated using the appropriate ISR and the delta watts and hours from the install year.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = ((WattsBase - WattsEE) / 1000) * ISR * (1-Leakage) * WHFd * CF$$

Where:

WHFd = Waste heat factor for demand to account for cooling savings from efficient lighting.

Bulb Location	WHFd
Interior single family	1.11[1359]
Multifamily in unit	1.07[1360]
Exterior or uncooled location	1.0
Unknown location	1.093[1361]

CF = Summer Peak Coincidence Factor for measure.

Bulb Location	CF
Interior	0.128[1362]
Exterior	0.273[1363]
Unknown	0.135[1364]

[1358] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[1359] The value is estimated at 1.11 (calculated as 1 + (0.66 * 0.466 / 2.8)). See footnote relating to WHFe for details. Note the 46.6% factor represents the average Residential cooling coincidence factor calculated by dividing average load during the peak hours divided by the maximum cooling load.

[1360] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1361] Unknown is weighted average of interior v exterior (assuming 5% exterior lighting based on distribution of LEDs from on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study) and SF v MF interior based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1362] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1363] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.

[1364] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

Other factors as defined above

For example: for the same 4W LED that is installed in a single family interior location through a ComEd upstream program:

ΔkW = ((25 - 4) / 1000) * 0.784 * (1-0.008) * 1.11 * 0.128

= 0.0023 kW

Second and third year install savings should be calculated using the appropriate ISR and the delta watts and hours from the install year.

FOSSIL FUEL SAVINGS

Heating penalty if Natural Gas heated home, or if heating fuel is unknown.

ΔTherms = - (((WattsBase - WattsEE) / 1000) * ISR * (1-Leakage) * Hours * HF * 0.03412) / ηHeat

Where:

HF = Heating factor, or percentage of lighting savings that must be replaced by heating system.

= 49% for interior[1365]

= 0% for exterior location

= 42% for unknown location[1366]

0.03412 = Converts kWh to Therms

ηHeat = Average heating system efficiency.

= 0.70 [1367]

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

For Omni-directional A-lamps, the baseline lamp is assumed to need replacing after 1000 hours. Therefore a baseline cost of $1.25 should be applied every 0.92 years for interior applications, 0.40 years for exterior applications and 0.86 years for unknown.

For Decorative a baseline cost of $1.74 should be applied every 0.92 years for interior applications, 0.40 years for exterior applications and 0.86 years for unknown.

[1365] Average result from REMRate modeling of several different configurations and IL locations of homes

[1366] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1367] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey) In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

For Directional a baseline cost of $3.53 should be applied every 0.92 years for interior applications, 0.40 years for exterior applications and 0.86 years for unknown.

For Linear Task/Under Cabinet and T-LEDs, with a linear fluorescent baseline, there is assumed no O&M impact since the baseline lamp life is 18,000 – 30,000 hours and which is longer than the assumed measure life.

It is important to note that for cost-effectiveness screening purposes, the O&M cost adjustments should only be applied in cases where the light bulbs area actually in service and so should be multiplied by the appropriate ISR.

MEASURE CODE: RS-LTG-LEDE-V4-260101

REVIEW DEADLINE: 1/1/2028

5.5.14 Ultra-Efficient LED Lighting

DESCRIPTION

This characterization provides savings assumptions for a variety of ultra-efficient LED screw-based lamp types including omnidirectional and specialty (globe, decorative and downlights) types. This characterization assumes that the LED lamp is installed in a residential location. Where the implementation strategy does not allow for the installation location to be known (e.g., an upstream retail program not in a store 'easily accessed by income qualified communities' (see discussion below)) a deemed split of 97% Residential and 3% Commercial assumptions should be used.

This measure was developed to be applicable to the following program types: TOS, NC, EREP, KITS, DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

In order for this characterization to apply, new lamps must exceed efficiency specifications defined in the Baseline Efficacy Tables below. Consult the tables to find the *minimum efficacy* that can be considered ultra-efficient for each bulb type.

Actual lamp wattages of the efficient equipment should be used to determine savings.

DEFINITION OF BASELINE EQUIPMENT

For TOS, NC or Kit programs, the baseline equipment is a standard LED bulb. See Baseline Efficacy tables below for specific baseline efficacies by lamp type and lumen output.

For Direct Install programs where it can be shown that the LED bulb is replacing working inefficient lighting, the existing inefficient lighting is baseline for the assumed remaining life of the existing lamp, and a standard LED bulb for the remainder of the measure life. A mid-life adjustment is therefore applied after 2 years, see Mid-Life Adjustment section below.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

According to the ENERGY STAR[1368] Qualified Products list (accessed 6/16/2020), the average rated life for Omnidirectional lamps is approximately 20,000 hours, 17,000 hours for decorative and 25,000 for directional lamps. Measure life is should be calculated by dividing these rated life assumptions with the hours of use. For direct install programs, a mid-life adjustment is applied after 2 years.

DEEMED MEASURE COST

The actual ultra-efficient LED lamp cost should be used. For incremental cost, assume a baseline cost according to the following table[1369]:

Bulb Type	Standard LED Baseline Cost
Omnidirectional	$2.70
Directional	$5.18
Decorative and Globe	$3.40

[1368] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[1369] Baseline and LED lamp costs are based on field data collected by CLEAResult and provided by ComEd. See ComEd Pricing Projections 06302016.xlsx for analysis. Given LED prices are expected to continue declining assumed costs should be reassessed on an annual basis and replaced with IL specific LED program information when available.

For Direct Install, assume the full ultra-efficient LED install cost, and a deferred baseline replacement cost (after 2 years) as provided above. This cost should be discounted to present value using the nominal societal discount rate.

LOADSHAPE

Loadshape R06 – Residential Indoor Lighting

Loadshape R07 – Residential Outdoor Lighting

COINCIDENCE FACTOR

For omnidirectional: The summer peak coincidence factor is assumed to be 0.128 for Residential and in-unit Multi Family bulbs,[1370] 0.273 for exterior bulbs,[1371] and 0.135 for unknown,[1372]

For specialty bulbs: The summer peak coincidence factor is assumed to be 0.109 for residential and in-unit multifamily bulbs,[1373], 0.273 for exterior bulbs[1374] and 0.117 for unknown[1375].

Use Multifamily if the building meets the utility's definition for multifamily.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \left(\frac{(Wattsbase - WattsEE)}{1000}\right) * ISR * (1 - Leakage) * Hours * WHFe$$

Where:

$Watts_{base}$ = LumensEE / $Efficacy_{Base}$

LumensEE = Lumens of ultra-efficient lamp

= Actual

$Efficacy_{Base}$ = Efficacy (Lumens/Watt) or standard efficiency LED baseline bulb.

= See table below[1376]:

[1370] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1371] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.

[1372]Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1373] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1374] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for specialty LEDs in exterior applications.

[1375] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1376] Average lumens per watt for each lamp type as provided in standard LED measures, based on Guidehouse file "LED Lamp Updates 2021-06-09".

Lamp Type	Minimum Lumens	Maximum Lumens	$Efficacy_{Base}$ (Lumens/Watt)
Omnidirectional	120	3,299	93.6
Decorative	310	2,700	100.6
Directional	310	3,299	81.6
Additional EISA Non-Exempt Bulb Types	310	1,999	91.1

.

$Watts_{EE}$ = Actual wattage of LED purchased / installed must be used. ISR = In Service Rate, the percentage of lamps rebated that are actually in service.

Program		In Service Rate (ISR)[1377]
Retail (Time of Sale)		97.4%[1378]
Direct Install		94.5%[1379]
Virtual Assessment followed by Unverified Self-Install		97.5%[1380]
Efficiency Kits[1381]	LED Distribution[1382]	82.3%
	School Kits[1383]	83.3%
	Direct Mail Kits[1384]	91.2%
	Community Distributed Kits[1385]	94.8%

[1377] In Service Rates now represent the lifetime In Service Rates with the second and third year installations discounted by the Real Discount Rate of 2.0%. Lifetime ISR assumptions for efficiency kits are based upon comparing with CFL Distribution First year ISR and multiplying by the CFL Distribution Final ISR value, capped at 95%, and second and third year estimates based on same proportion of future installs. For all other programs Tthe 98% Lifetime ISR assumption is based upon the standard CFL measure in the absence of any better reference. This value is based upon review of two evaluations:
'Nexus Market Research, RLW Analytics and GDS Associates study; "New England Residential Lighting Markdown Impact Evaluation, January 20, 2009' and 'KEMA Inc, Feb 2010, Final Evaluation Report:, Upstream Lighting Program, Volume 1.' This implies that only 2% of bulbs purchased are never installed. The second and third year installations are based upon Ameren analysis of the Californian KEMA study showing that 54% of future installs occur in year 2 and 46% in year 3.
[1378] 1st year in service rate is based upon analysis of ComEd PY8, PY9 and CY2018 and Ameren PY8 intercept data (see 'RES Lighting ISR_2019.xlsx' for more information).
[1379] Based upon average of Navigant low income single family direct install field work LED ISR and Standard CFL assumption in the absence of better data, and is based upon review of the PY2 and PY3 ComEd Direct Install program surveys. This value includes bulb failures in the 1st year to be consistent with the Commission approval of annualization of savings for first year savings claims. ComEd PY2 All Electric Single Family Home Energy Performance Tune-Up Program Evaluation, Navigant Consulting, December 21, 2010.
[1380] An equal weighted average of Direct Install and Direct Mail Kit ISRs. Interest and applicability of measures confirmed through virtual assessment.
[1381] In Service Rates provided are for the bulb within a kit only. Given the significant differences in program design and the level of education provided through Efficiency Kits programs, the evaluators should apply the ISR estimated through evaluations (either past evaluations or the current program year evaluation) of the specific Efficiency Kits program. In cases where program-specific evaluation results for an ISR are unavailable, the default ISR values for Efficiency Kits provide may be used.
[1382] Free bulbs provided without request, with little or no education. Consistent with Standard CFL assumptions.
[1383] 1st year ISR for school kits based on ComEd PY9 data for the Elementary Energy Education program. Final ISR assumptions are based upon comparing with CFL Distribution First year ISR and multiplying by the CFL Distribution Final ISR value, and second and third year estimates based on same proportion of future installs.
[1384] Opt-in program to receive kits via mail, with little or no education. Consistent with Standard CFL assumptions.
[1385] Kits distributed in a community setting, targeted to income qualified communities. Research from 2018 Ameren Illinois Income Qualified participant survey.

Program	In Service Rate (ISR)[1377]
Food Bank / Pantry Distribution[1386]	97.5%[1387]

Leakage = Adjustment to account for the percentage of program bulbs that move out (and in if deemed appropriate)[1388] of the Utility Jurisdiction.

KITS programs = Determined through evaluation

Upstream (TOS) Lighting programs = Use deemed assumptions below:[1389]

ComEd: 0.95%

Ameren: 13.1%

All other programs = 0

Hours = Average hours of use per year depending on bulb type

Installation Location	Omnidirectional Hours	Specialty Hours
Residential and in-unit Multi Family	1,089[1390]	763[1391]
Exterior	2,475[1392]	2,475[1393]
Unknown	1,159[1394]	1,020[1395]

WHFe = Waste heat factor for energy to account for cooling energy savings from efficient lighting

Bulb Location	WHFe
Interior single family	1.06 [1396]

[1386] Free bulbs provided through local food banks and food pantries.

[1387] 1st year ISR is determined based on online surveys conducted for ComEd CY2018 Food Bank LED Distribution program. See 'CY2018 ComEd Foodbank LED Dist Survey Results_Navigant'.

[1388] Leakage in is only appropriate to credit to IL utility program savings if it is reasonably expected that the IL utility program marketing efforts played an important role in influencing customer to purchase the light bulbs. Furthermore, consideration that such customers might be free riders should be addressed. If leakage in is assessed, efforts should be made to ensure no double counting of savings occurs if the evaluation is estimating both leakage in and spillover savings of light bulbs.

[1389] Leakage rate is based upon an average of the decorative and omnidirectional leakage values provided fom a review of evaluations from ComEd and Ameren.

[1390] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1391] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1392] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. The IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide hours of use for screw-based omnidirectional LEDs in exterior applications.

[1393] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. The IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide hours of use for specialty LEDs in exterior applications.

[1394] Based on a weighted average of hours of use in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1395] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1396] The value is estimated at 1.06 (calculated as 1 + (0.66*(0.27 / 2.8)). Based on cooling loads decreasing by 27% of the lighting savings (average result from REMRate modeling of several different configurations and IL locations of homes), assuming

Bulb Location	WHFe
Multifamily in unit	1.04 [1397]
Exterior or uncooled location	1.0
Unknown location	1.049[1398]

HEATING PENALTY

If electric heated home (if heating fuel is unknown assume gas, see Fossil Fuel section):

$$\Delta kWh^{1399} = -\frac{((WattsBase - WattsEE) * ISR * (1-Leakage) * Hours * HF)}{1{,}000 * \eta Heat}$$

Where:

HF = Heating Factor or percentage of light savings that must be heated

= 49% for interior[1400]

= 0% for exterior or unheated location

= 42% for unknown location[1401]

ηHeat = Efficiency in COP of Heating equipment

= actual. If not available use:[1402]

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Heat Pump (if age unknown assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00

typical cooling system operating efficiency of 2.8 COP (starting from standard assumption of SEER2 13.4 central AC unit, converted to 11.4 EER2 using algorithm (-0.02 * $SEER^2$) + (1.12 * SEER) (from Wassmer, M. (2003). A Component-Based Model for Residential Air Conditioner and Heat Pump Energy Calculations. Masters Thesis, University of Colorado at Boulder), converted to COP and including distribution efficiency = EER2 * 0.85/3.412 = 2.8COP) and 66% of homes in Illinois having central cooling ("Table HC7.9 Air Conditioning in Homes in Midwest Region, Divisions, and States, 2009 from Energy Information Administration", 2009 Residential Energy Consumption Survey)

[1397] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1398] Unknown is the average of the 5.5.6 LED Specialty Lamps and 5.5.8 LED Screw Based Omnidirectional Bulbs unknown assumptions.

[1399] Negative value because this is an increase in heating consumption due to the efficient lighting.

[1400] This means that heating loads increase by 49% of the lighting savings. This is based on the average result from REMRate modeling of several different configurations and IL locations of homes.

[1401] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1402] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note efficiency should include duct losses. Defaults provided assume 15% duct loss for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate	COP_{HEAT} (COP Estimate) = (HSPF2/3.412)*0.85
Unknown[1403]	N/A	N/A	1.28

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = \frac{(WattsBase - WattsEE)}{1000} * ISR * (1 - Leakage) * WHFd * CF$$

Where:

WHFd = Waste heat factor for demand to account for cooling savings from efficient lighting.

Bulb Location	WHFd
Interior single family	1.11[1404]
Multifamily in unit	1.07[1405]
Exterior or uncooled location	1.0
Unknown location	1.088[1406]

CF = Summer Peak Coincidence Factor for measure. See table depening on the bulb type

Bulb Location	Omnidirectional CF	Specialty CF
Interior	0.128[1407]	0.109[1408]
Exterior	0.273[1409]	0.273[1410]
Unknown	0.135[1411]	0.177[1412]

[1403] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[1404] The value is estimated at 1.11 (calculated as 1 + (0.66 * 0.466 / 2.8)). See footnote relating to WHFe for details. Note the 46.6% factor represents the average Residential cooling coincidence factor calculated by dividing average load during the peak hours divided by the maximum cooling load.

[1405] As above but using estimate of 45% of multifamily buildings in Illinois having central cooling (based on data from "Table HC7.1 Air Conditioning in U.S. Homes, By Housing Unit Type, 2009" which is for the whole of the US, scaled to IL air conditioning prevalence compared to US average)

[1406] Unknown is the average of the 5.5.6 LED Specialty Lamps and 5.5.8 LED Screw Based Omnidirectional Bulbs unknown assumptions.

[1407] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1408] Based on the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs.

[1409] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for screw-based omnidirectional LEDs in exterior applications.

[1410] Based on lighting logger study conducted as part of the PY5/6 ComEd Residential Lighting Program evaluation. the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs was unable to provide coincidence factors for specialty LEDs in exterior applications.

[1411] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1412] Based on a weighted average of coincidence factors in interior and exterior applications, assuming 5% exterior lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

Other factors as defined above

FOSSIL FUEL SAVINGS

Heating penalty if Natural Gas heated home, or if heating fuel is unknown.

$$\Delta\text{Therms} = -\frac{((WattsBase - WattsEE) * ISR * (1-Leakage) * Hours * HF * 0.03412)}{1{,}000 * \eta Heat}$$

Where:

HF = Heating factor, or percentage of lighting savings that must be replaced by heating system.
= 49% for interior[1413]
= 0% for exterior location
= 42% for unknown location[1414]

0.03412 = Converts kWh to Therms

ηHeat = Average heating system efficiency.
= 0.70 [1415]

MID-LIFE ADJUSTMENT

For Direct Install programs a mid-life adjustment should be applied after two years. To calculate the adjustment perform the following calculation:

$$\text{Mid-life adjustment} = \frac{(Standard\ LED\ Lamp\ wattage - Ultra\ Efficient\ Lamp\ Wattage)}{(Existing\ Replaced\ Lamp\ Wattage - Ultra\ Efficient\ Lamp\ Wattage)}$$

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

MEASURE CODE: RS-LTG-ULED-V2-260101

REVIEW DEADLINE: 1/1/2029

[1413] Average result from REMRate modeling of several different configurations and IL locations of homes

[1414] Based on a weighted average of interior and exterior hours of use from the IL Statewide LED Lighting Logger study conducted as part of the PY8/PY9 evaluations of the Ameren Illinois and ComEd Residential Lighting programs, assuming 15% exterior specialty lighting. The distribution of LEDs is based on the on-site lighting inventory conducted as part of the IL Statewide LED Lighting Logger study.

[1415] This has been estimated assuming that natural gas central furnace heating is typical for Illinois residences (66% of Illinois homes have a Natural Gas Furnace (based on Energy Information Administration, 2009 Residential Energy Consumption Survey) In 2000, 24% of furnaces purchased in Illinois were condensing (based on data from GAMA, provided to Department of Energy during the federal standard setting process for residential heating equipment - see Furnace Penetration.xls). Furnaces tend to last up to 20 years and so units purchased 10 years ago provide a reasonable proxy for the current mix of furnaces in the State. Assuming typical efficiencies for condensing and non-condensing furnaces and duct losses, the average heating system efficiency is estimated as follows:
(0.24*0.92) + (0.76*0.8) * (1-0.15) = 0.70

5.6 Shell End Use

5.6.1 Air Sealing

DESCRIPTION

Thermal shell air leaks are sealed through strategic use and location of air-tight materials. Leaks are detected and leakage rates measured with the assistance of a blower-door. The algorithm for this measure can be used when the program implementation does not allow for more detailed forecasting through the use of residential modeling software. Prescriptive savings are provided for use only when a blower door test is not conducted. Note, the prescriptive assumptions of savings for a can of spray foam are tagged as Provisional.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Air sealing materials and diagnostic testing should meet all eligibility program qualification criteria. The initial and final tested leakage rates should be performed in such a manner that the identified reductions can be properly discerned, particularly in situations wherein multiple building envelope measures may be implemented simultaneously.

DEFINITION OF BASELINE EQUIPMENT

The existing air leakage should be determined through approved and appropriate test methods using a blower door. The baseline condition of a building upon first inspection significantly impacts the opportunity for cost-effective energy savings through air-sealing. Savings are provided for prescriptive air sealing measures when a blower door test is not conducted.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years.[1416]

The expected measure life of prescriptive shrink-fit window film is assumed to be 1 year.

Note a mid-life adjustment to account for replacement of HVAC equipment during the measure life should be applied after 10 years or 13 years for boilers.[1417] See section below for detail.

DEEMED MEASURE COST

The actual capital cost for this measure should be used in screening.

LOADSHAPE

Loadshape R08 - Residential Cooling

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's capacity market.

[1416] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.

[1417] This is intentionally longer than the assumptions found in the early replacement measures as the application of this measure will occur in a variety of homes that will not be targeted for early replacement HVAC systems.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1418]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

= 72%[1419]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[1420]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1421]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1422]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Methodology 1: Blower Door Test

Required methodology when blower door testing is conducted.

$$\Delta kWh = \Delta kWh_cooling + \Delta kWh_heatingElectric + \Delta kWh_heatingFurnace$$

Where:

ΔkWh_cooling = If central cooling, reduction in annual cooling requirement due to air sealing

$$= [(((CFM50_existing - CFM50_new)/N_cool) * 60 * 24 * CDD * DUA * LoadFactor * 0.018) / (1{,}000 * \eta Cool) * LM * ADJ_{AirSealingCool}] * IE_{NetCorrection} * \%Cool$$

CFM50_existing = Infiltration at 50 Pascals as measured by blower door before air sealing.

= Actual

[1418] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[1419] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[1420] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015
[1421] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1422] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

CFM50_new = Infiltration at 50 Pascals as measured by blower door after air sealing.

= Actual

N_cool = Conversion factor from leakage at 50 Pascal to leakage at natural conditions

=Dependent on location and number of stories:[1423]

Climate Zone (City based upon) [1424]	N_cool (by # of stories)			
	1	1.5	2	3 +
1 (Rockford)	39.5	35.0	32.1	28.4
2 (Chicago)	38.9	34.4	31.6	28.0
3 (Springfield)	41.2	36.5	33.4	29.6
4 (St Louis, MO)	40.4	35.8	32.9	29.1
5 (Paducah, KY)	43.6	38.6	35.4	31.3

60 * 24 = Converts Cubic Feet per Minute to Cubic Feet per Day

CDD = Cooling Degree Days

= Dependent on location:[1425]

Climate Zone (City based upon)	CDD 65
1 (Rockford)	877
2 (Chicago)	1047
3 (Springfield)	1183
4 (Belleville)	1641
5 (Marion/Murphysboro)	1450

DUA = Discretionary Use Adjustment (reflects the fact that people do not always operate their AC when conditions may call for it).

= 0.90 [1426]

LoadFactor = Factor to reflect expected relative load (and therefore savings) or homes with Room AC v Central AC.

[1423] N-factor is used to convert 50-pascal blower door air flows to natural air flows and is dependent on geographic location and # of stories. These were developed by applying the LBNL infiltration model (see LBNL paper 21040, *Exegisis of Proposed ASHRAE Standard 119: Air Leakage Performance for Detached Single-Family Residential Buildings*; Sherman, 1986; page v-vi, Appendix page 7-9) to the reported wind speeds and outdoor temperatures provided by the NRDC 30 year climate normals. For more information see Bruce Harley, CLEAResult "Infiltration Factor Calculations Methodology.doc".

[1424] Note, the methodology for developing n-factors requires hourly normals as opposed to annual normals which are used for other assumptions in the TRM. Hourly normals were not available for all sites used for other climate assumptions and so the nearest locations were used (St Louis, MO for Belleville, IL and Paducah, KY for Marion, IL).

[1425] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 65°F.

[1426] This factor utilizes data from a metering study: Pigg, Scott, D. Cautley, and K. Koski, (2016). "Improving Installation and Maintenance Practices for Minnesota Residential Furnaces, Air Conditioners and Heat Pumps", prepared for Minnesota Department of Commerce, Division of Energy. COMM-201305222-72623. To correct for the different climatological conditions in Minnesota and Illinois, the analysis includes 19 homes that have actual annual operating hours above 453 hrs/yr (over ½ of the actual annual operating hours for the highest operating hours homes in the study-905 hrs/yr). Additionally, the factor is adjusted from 0.87 to 0.90 to account for Illinois' hotter climate and higher number of muggy days. See DUA_Workbook_051525.xlsx for detailed data. .

= 1.0 for homes with central AC, 0.41 for homes with Room AC[1427]

0.018 = Specific Heat Capacity of Air (Btu/ft^3*°F)

1000 = Converts Btu to kBtu

ηCool = Efficiency (SEER2 or CEER) of Air Conditioning equipment (kBtu/kWh) * Distribution Efficiency

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for central cooling with ducts if only equipment efficiency is available). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1428] or if unknown assume the following.[1429] If unknown value is used, it should not be derated by age.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3
Room AC[1430]		
Non-IQ	10.9	10.9
IQ	9.7	9.7
Unknown (for use in program evaluation only)[1431]		
Single Family Non-IQ		10.6
Single Family IQ		10.3
Multi Family Non-IQ		10.3
Multi Family IQ		9.9
Unknown		10.3

LM = Latent multiplier to account for latent cooling demand[1432]

[1427] Based upon review of 102 room AC replacement projects completed in 2023 and 2024 for an Illinois multifamily energy efficiency program, the average room AC capacity installed was 11.41 MBh per living unit. From Section 5.3.3 for Central Air Conditioning, default central A/C capacity is 28 MBh. This results in a capacity scale factor of 11.41 / 28 = 0.41 when using room air conditioner cooling.

[1428] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1429] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

[1430] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[1431] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1432] Derived by calculating the sensible and total loads in each hour. For more information see Bruce Harley, CLEAResult "Infiltration Factor Calculations Methodology.doc". Note, the methodology requires hourly normals as opposed to annual normals which are used for other assumptions in the TRM. Hourly normals were not available for all sites used for other climate assumptions and so the nearest locations were used (St Louis, MO for Belleville, IL and Paducah, KY for Marion, IL).

Climate Zone (City based upon)	LM
1 (Rockford)	3.3
2 (Chicago)	3.2
3 (Springfield)	3.7
4 (St Louis, MO)	3.6
5 (Paducah, KY)	3.7

$ADJ_{AirSealingCool}$ = Adjustment for cooling savings to account for inaccuracies in engineering algorithms[1433]

Measure	$ADJ_{AirSealingCool}$
Air sealing and attic insulation	114%
Air sealing without attic insulation	100%

$IE_{NetCorrection}$ = 100% if not income eligible or air sealing is installed without attic insulation.

= 110% if installing air sealing and attic insulation in income eligible projects with a deemed NTG value of 1.0 to offset net savings adjustment inherent when using $ADJ_{AirSealingCool}$ of 114% [1434]

%Cool = Percent of homes that have cooling

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[1435]	98.9%	96.5%	99.8%	98.7%	98.6%

ΔkWh_heatingElectric = If electric heat (resistance baseboard, electric furnace or heat pump), reduction in annual electric heating due to air sealing

= [(((CFM50_existing - CFM50_new)/N_heat) * 60 * 24 * HDD * 0.018) /ηHeat] *%ElectricHeat

N_heat = Conversion factor from leakage at 50 Pascal to leakage at natural conditions

[1433] As demonstrated in air sealing and insulation research by Navigant, see Navigant (2018). C*omEd and Nicor Gas Air Sealing and Insulation Research Report.* Presented to Commonwealth Edison Company and Nicor Gas Company.
These adjustment factors are based on a consumption data analysis using matching to non-participants. The values are therefore between net and gross with respect to free ridership. Like all consumption data analyses, they are net with respect to participant spillover and gross with respect to non-participant spillover. For more detail, see Table 5-3 in Volume 4 of the IL-TRM. Consistent with Section 7.2 of the Illinois EE Policy Manual, applicable net-to-gross adjustments to the savings will be determined as part of the annual SAG net-to-gross process. During update cycle for version v.12, applied the percent change of NCEI Annual Normals CDD65 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all cooling-related adjustment values.

[1434] The additional value of 10% was selected to acknowledge that some portion of the regression-derived adjustment factors accounts for gross impact effects, and that removing net effects embedded in the adjustment factors would increase savings to some degree. A review of historical NTG values for air sealing and insulation measures in non-income eligible populations did not provide definitive guidance for estimating the net component of the adjustment factors. Historically, free ridership has ranged from 9% to 26% for like measures, and spillover has ranged from 1% to 14%, while NTGs have ranged from 0.75 to 1.05. The midpoint of the NTG range would be 0.90, a 10% reduction from 1.0.

[1435] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

= Based on climate zone, building height and exposure level:[1436]

Climate Zone (City based upon)	N_heat (by # of stories)			
	1	1.5	2	3 +
1 (Rockford)	23.8	21.1	19.3	17.1
2 (Chicago)	23.9	21.1	19.4	17.2
3 (Springfield)	24.2	21.5	19.7	17.4
4 (St Louis, MO)	25.4	22.5	20.7	18.3
5 (Paducah, KY)	27.8	24.6	22.6	20.0

HDD = Heating Degree Days

= Dependent on location:[1437]

Climate Zone (City based upon)	HDD 60
1 (Rockford)	5230
2 (Chicago)	4798
3 (Springfield)	4266
4 (Belleville)	3188
5 (Marion/Murphysboro)	3390

ηHeat = Efficiency of heating system

= Actual heat efficiency * distribution efficiency (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1438] or if not available refer to default table below.[1439] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85% for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) = (HSPF2/3.412)*0.85
Heat Pump	Before 2006	5.8	1.44

[1436] N-factor is used to convert 50-pascal blower door air flows to natural air flows and is dependent on geographic location and # of stories. These were developed by applying the LBNL infiltration model (see LBNL paper 21040, *Exegisis of Proposed ASHRAE Standard 119: Air Leakage Performance for Detached Single-Family Residential Buildings*; Sherman, 1986; page v-vi, Appendix page 7-9) to the reported wind speeds and outdoor temperatures provided by the NRDC 30 year climate normals. For more information see Bruce Harley, CLEAResult "Infiltration Factor Calculations Methodology.doc". Note, the methodology for developing n-factors requires hourly normals as opposed to annual normals which are used for other assumptions in the TRM. Hourly normals were not available for all sites used for other climate assumptions and so the nearest locations were used (St Louis, MO for Belleville, IL and Paducah, KY for Marion, IL).

[1437] National Climatic Data Center, calculated from 1981-2010 climate normals with a base temp of 60°F.

[1438] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1439] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) = (HSPF2/3.412)*0.85
(if age unknown assume 2006-2014)	2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown (for use in program evaluation only)[1440]	N/A	N/A	1.32

3412 = Converts Btu to kWh

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump
= 0 % for Fossil Fuels

= If unknown[1441], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[1442]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

[1440] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

[1441] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1442] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

For example: energy savings from air sealing. Energy savings for attic insulation are included in a separate example in Section 5.6.5: Ceiling/Attic Insulation.

Assume a 2-story single family non-income eligible home in Chicago completes air sealing, installs attic insulation, has 10.5 SEER central cooling and a heat pump with COP of 2 (1.92 including distribution losses), and has pre and post blower door test results of 3,400 and 2,250 CFM:

ΔkWh = ΔkWh_cooling + ΔkWh_heating

= [(((3,400 – 2,250) / 31.6) * 60 * 24 * 1,047 * 0.90 * 0.018) / (1,000 * 10.5) * 3.2 * 114%] * 100% * 100% + [(((3,400 – 2,250) / 19.4) * 60 * 24 * 4,798 * 0.018) / (1.92 * 3,412)] * 100%

= 308.8 + 1,125

= 1,433.8 kWh

ΔkWh_heatingFurnace = If *furnace* (fossil fueled or electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = ΔTherms * F_e * 29.3 * $ADJ_{AirSealingHeatFan}$

If electric furnace: = ΔkWh_heating * F_e * $ADJ_{AirSealingHeatFan}$

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[1443]

29.3 = kWh per therm

$ADJ_{AirSealingHeatFan}$ = Adjustment for fan savings during heating season to account for inaccuracies in engineering algorithms[1444]

Measure	$ADJ_{AirSealingHeatFan}$
Air sealing and attic insulation	113%
Air sealing without attic insulation	100%

For example: energy savings from air sealing. Energy savings for attic insulation are included in a separate example in Section 5.6.5: Ceiling/Attic Insulation.

Assume a well shielded, 2-story non-income eligible single family home in Chicago completes air sealing, installs attic insulation, has a gas furnace with system efficiency of 70%, and has pre and post blower door test results of 3,400 and 2,250 CFM (see therm calculation in Fossil Fuel Savings section):

ΔkWh_heatingGas = 77.8 * 0.0314 * 29.3 * 113%

= 80.8 kWh

[1443] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[1444] As demonstrated in air sealing and insulation research by Navigant, see Navigant (2018). C*omEd and Nicor Gas Air Sealing and Insulation Research Report.* Presented to Commonwealth Edison Company and Nicor Gas Company. These adjustment factors are based on a consumption data analysis using matching to non-participants. The values are therefore between net and gross with respect to free ridership. Like all consumption data analyses, they are net with respect to participant spillover and gross with respect to non-participant spillover. For more detail, see Table 5-3 in Volume 4 of the IL-TRM. Consistent with Section 7.2 of the Illinois EE Policy Manual, applicable net-to-gross adjustments to the savings will be determined as part of the annual SAG net-to-gross process. During update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all heating-related adjustment values.

Methodology 2: Prescriptive Infiltration Reduction Measures[1445]

Savings shall only be calculated via Methodology 2 if a blower door test is not conducted.

$\Delta kWh = (\Delta kWh_Heating + \Delta kWh_Cooling) * ADJ_{RxAirsealing}$

$\Delta kWh_Heating = (\Delta kWh_{gasket_heat} * n_{gasket} * ISR + \Delta kWh_{windows_heat} * sf_{windows} * ISR + \Delta kWh_{sweep_heat} * n_{sweep} * ISR + \Delta kWh_{spray\ foam} * Oz_{spray\ foam} * ISR + \Delta kWh_{sealing_heat} * lf_{sealing} * ISR + \Delta kWh_{WX_heat} * lf_{WX} * ISR)$

$\Delta kWh_Cooling = (\Delta kWh_{gasket_cool} * n_{gasket} * ISR + \Delta kWh_{windows_cool} * sf_{windows} * ISR + \Delta kWh_{sweep_cool} * n_{sweep} * ISR + \Delta kWh_{sealing_cool} * lf_{sealing} * ISR + \Delta kWh_{WX_cool} * lf_{WX} * ISR)$

Where:

ΔkWh_{gasket} = Annual kWh savings from installation of air sealing gasket on an electric outlet on an external wall.

Climate Zone	ΔkWh_{gasket_heat} / gasket		ΔkWh_{gasket_cool} / gasket		
(City based upon)	Electric Resistance (Baseboard or Electric Furnace)	Heat Pump	With Central Cooling	With Room AC Cooling[1446]	Unknown Cooling[1447]
1 (Rockford)	10.5	5.3	1	0.41	0.86
2 (Chicago)	10.2	5.1	1.2	0.49	1.04
3 (Springfield)	8.8	4.4	1.4	0.57	1.21
4 (Belleville)	7	3.5	2	0.82	1.73
5 (Marion)	7.2	3.6	1.7	0.70	1.47

n_{gasket} = Number of gaskets installed

$\Delta kWh_{windows}$ = Annual kWh savings from installation of Shrink-Fit Window Kit[1448]

Climate Zone	$\Delta kWh_{windows_heat}$ / square ft	
(City based upon)	Electric Resistance (Baseboard or Electric Furnace)	Heat Pump
1 (Rockford)	4	2.1
2 (Chicago)	3.9	2

[1445] Prescriptive savings are based upon "Evaluation of the Weatherization Residential Assistance Partnership and Helps Programs (WRAP/Helps)." Middletown, CT: KEMA, 2010. Accessed July 30, 2015, and adjusted for relative HDD of Bridgeport/Hartford CT with the IL climate zones. See 'Rx Airsealing HDD adjustment.xls' for more information. Cooling savings derived using savings assumptions pulled from ASHRAE, 2001 AHSRAE Handbook – Fundamentals, Chapter 26, Table 1. Effective Air Leakage Areas (Low-Rise Residential Applications Only). See 'Prescriptive Air Sealing Cooling Calculation.xls' for details.

[1446] Estimated by multiplying by 0.41 LoadFactor described above.

[1447] Unknown cooling values in all tables are based on 78% of homes having Central AC, 20.6% having window AC and 1.6% having no AC, assumptions derived from GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1448] Prescriptive savings are based upon "Cost Benefit Analysis for 2018, Annual Report submitted to Virginia Natural Gas, Inc., submitted by Nexant." July 31, 2018. Adjusted for relative HDD of Virginia Beach VA with the IL climate zones. See "Window Film Savings Calculation.xlsx" for more information.

Climate Zone	$\Delta kWh_{windows_heat}$ / square ft	
(City based upon)	Electric Resistance (Baseboard or Electric Furnace)	Heat Pump
3 (Springfield)	3.3	1.7
4 (Belleville)	2.5	1.3
5 (Marion)	2.6	1.3

$sf_{windows}$ = square footage of shrink-fit window film

ΔkWh_{sweep} = Annual kWh savings from installation of a door sweep on a door between conditioned and unconditioned space

Climate Zone	ΔkWh_{sweep_heat} / sweep		ΔkWh_{sweep_cool} / sweep		
(City based upon)	Electric Resistance (Baseboard or Electric Furnace)	Heat Pump	With Central Cooling	With Room AC Cooling[1449]	Unknown Cooling
1 (Rockford)	202.4	101.2	3.9	1.60	3.37
2 (Chicago)	195.3	97.6	4.6	1.89	3.98
3 (Springfield)	169.3	84.7	5.7	2.34	4.93
4 (Belleville)	134.9	67.5	7.8	3.20	6.74
5 (Marion)	137.9	68.9	6.6	2.71	5.71

n_{sweep} = Number of sweeps installed

$\Delta kWh_{spray\ foam}$ = Annual kWh savings per ounce of spray foam product[1450]

NOTE: Saving assumptions for spray foam below are Provisional.

$\Delta kWh_{spray\ foam}$ per oz (heating)		$\Delta kWh_{spray\ foam}$ per oz (cooling)		
Electric Resistance (Baseboard or Electric Furnace)	Heat Pump	With Central Cooling	With Room AC Cooling[1451]	Unknown Cooling
27.4	16.9	0.61	0.25	0.52

$Oz_{spray\ foam}$ = Ounce of spray foam product

= Actual (default of 12oz for consumer product (or if unknown) or 20 oz for professional product)

$\Delta kWh_{sealing}$ = Annual kWh per linear foot savings from other air sealing products such as caulk, or polyethlylene tape in locations between conditioned and unconditioned space.

[1449] Estimated by multiplying by 0.41 LoadFactor described above.
[1450] Savings derived from Bibee et al., "Air Sealing Existing Homes with Foam-in-a-Can Rivals Energy Cost Benefits of CFLs", ASHRAE 2010.See "ASHRAE spray foam paper quick analysis_VEIC.xls" for details.
[1451] Estimated by multiplying by 0.41 LoadFactor described above.

Climate Zone	$\Delta kWh_{sealing_heat}$ / linear ft		$\Delta kWh_{sealing_cool}$ / linear ft		
(City based upon)	Electric Resistance (Baseboard or Electric Furnace)	Heat Pump	With Central Cooling	With Room AC Cooling[1452]	Unknown Cooling
1 (Rockford)	11.6	5.8	0.11	0.05	0.10
2 (Chicago)	11.2	5.6	0.12	0.05	0.10
3 (Springfield)	9.7	4.8	0.15	0.06	0.13
4 (Belleville)	7.7	3.9	0.21	0.09	0.18
5 (Marion)	7.9	3.9	0.18	0.07	0.15

$lf_{sealing}$ = linear feet of caulking, sealing, spray foam or polyethylene tape

ΔkWh_{WX} = Annual kWh savings from window weatherstripping or door weatherstripping

Climate Zone	ΔkWh_{WX_heat} / linear ft		ΔkWh_{WX_cool} / linear ft		
(City based upon)	Electric Resistance (Baseboard or Electric Furnace)	Heat Pump	With Central Cooling	With Room AC Cooling[1453]	Unknown Cooling
1 (Rockford)	13.5	6.7	0.1	0.04	0.09

5 (Marion)	9.2	4.6	0.16	0.07	0.14

lf_{WX} = Linear feet of window weatherstripping or door weatherstripping

$ADJ_{RxAirsealing}$ = Adjustment for air sealing savings to account for prescriptive estimates overclaiming savings[1454]

= 80%

ISR = In service rate of weatherization kits dependent on install method as listed in table below.[1455]

[1452] Estimated by multiplying by 0.41 LoadFactor described above.
[1453] Estimated by multiplying by 0.41 LoadFactor described above.
[1454] Though we do not have a specific evaluation to point to, modeled savings have often been found to overclaim. Further VEIC reviewed these deemed estimates and consider them to likely be a high estimate. As such an 80% adjustment is applied, and this could be further refined with future evaluations.
[1455] For any airsealing kit measure, if research indicates that a certain percentage of participants who indicated during the original ISR survey that they plan to install are found to have actually installed at a later date, these future installs can be claimed as 2nd or 3rd year installs through an errata.

Selection	ISR
Distributed School Weatherization Kits	0.57[1456]
Distributed Self-Install Income-Qualified Kits[1457]	
Weatherstripping	0.63
Outlet and Switch Gaskets	0.40[1458]
Window Kit	0.57
Door sweep	0.62[1459]
Other Distributed Self-Install Income-Qualified Measures	0.67[1460]
Opt-in Weatherization Kits[1461]	
V-seal weatherstripping	0.68
Cell foam tape weatherstripping	0.72
Rope Caulk	0.60
Switch and outlet gaskets	0.76
Door sweep	0.68
Other Self-Install Weatherization Measures	0.69
Direct Install, Retail	1.0

[1456] Results from Home Energy Worksheets completed by student/families in 2020, 2021, and 2022 were nearly the same as values from: LLUME Advising LLC. School-Based Energy Education Programs: Goals, Challenges, and Opportunities. October 2015. See result for AEP Ohio Weather stripping/door sweep/gaskets kit in table on page 17. Home Energy Worksheets also establish the fraction of participants who indicate they "will install later" for specific measures. Follow-up research completed by Guidehouse for Nicor Gas in 2022 found that, on average, 51.3% of respondents who initially reported that they hadn't installed specific kit measures, but "planned to" subsequently had installed the measures. Combining these findings allows for an ISR that accounts for initial and one round of subsequent installations. To maintain a conservative estimate of ISR, the remaining 48.7% are presumed uninstalled. See: EESchoolKitSubsequentInstall_HEW.xlsx for data and calculations.

[1457] Guidehouse. Income Eligible Gas Kits ISR Special Study Results. June 16, 2020.

[1458] Research from 2021 Ameren Illinois Income Qualified participant survey, available on IL SAG website: https://ilsag.s3.amazonaws.com/AIC-Income-Qualified-Initiative-Participant-Survey-Results-Memo-FINAL-2022-02-01.pdf

[1459] Research from 2021 Ameren Illinois Income Qualified participant survey, available on IL SAG website: https://ilsag.s3.amazonaws.com/AIC-Income-Qualified-Initiative-Participant-Survey-Results-Memo-FINAL-2022-02-01.pdf

[1460] Straight average of other measures.

[1461] Table 16, Illinois TRM Workpaper ESK ISR Follow-up Survey 2023-05-30

For example, 5 gaskets, 2 door sweeps and 10 linear feet of window weatherstripping is provided in a Distributed Self-Install Income-Qualified Kits for a home in Rockford with electric resistance and cooling

$$\Delta kWh = (\Delta kWh_Heating + \Delta kWh_Cooling) * ADJ_{RxAirsealing}$$

$$\Delta kWh_Heating = (\Delta kWh_{gasket_heat} * n_{gasket} * ISR + \Delta kWh_{windows_heat} * sf_{windows} * ISR + \Delta kWh_{sweep_heat} * n_{sweep} * ISR + \Delta kWh_{sealing_heat} * lf_{sealing} * ISR + \Delta kWh_{WX_heat} * lf_{WX} * ISR)$$

$$\Delta kWh_Cooling = (\Delta kWh_{gasket_cool} * n_{gasket} * ISR + \Delta kWh_{windows_cool} * sf_{windows} * ISR + \Delta kWh_{sweep_cool} * n_{sweep} * ISR + \Delta kWh_{sealing_cool} * lf_{sealing} * ISR + \Delta kWh_{WX_cool} * lf_{WX} * ISR)$$

$\Delta kWh_Heating = (10.5 * 5 * 0.4) + (202.4 * 2 * 0.62) + (13.5 * 10 * 0.63)$

$= 357.0$ kWh

$\Delta kWh_Cooling = (1 * 5 * 0.4) + (3.9 * 2 * 0.62) + (0.1 * 10 * 0.63)$

$= 7.5$ kWh

$\Delta kWh = (357.0 + 7.5) * 0.8$

$= 291.6$ kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = (\Delta kWh_cooling / FLH_cooling) * CF$$

Where:

$\Delta kWh_cooling$ = Cooling savings from measure

$FLH_cooling$ = Full load hours of air conditioning

= Dependent on location:[1462]

Climate Zone (City based upon)	Single Family	Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1,082	982
5 (Marion/Murphysboro)	956	868
Weighted Average[1463]	676	603
ComEd	875	791
Ameren	731	655

[1462] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[1463] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

Climate Zone (City based upon)	Single Family	Multifamily
Statewide		

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[1464]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

= 72%[1465]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[1466]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[1467]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1468]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

Other factors as defined above.

For example: energy savings from air sealing. Energy savings for attic insulation are included in a separate example in Section 5.6.5: Ceiling/Attic Insulation.

Assume a well shielded, 2-story non-income eligible single family home in Chicago completes air sealing, installs attic insulation, has 10.5 SEER central cooling and a heat pump with COP of 2.0, and has pre and post blower door test results of 3,400 and 2,250 CFM:

ΔkW_{SSP} = 308.8 / 709 * 0.68

= 0.29 kW

ΔkW_{PJM} = 308.8 / 709 * 0.466

= 0.202 kW

[1464] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[1465] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[1466] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015
[1467] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1468] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

FOSSIL FUEL SAVINGS

Methodology 1: Blower Door Test

Required methodology when blower door testing is conducted.

If Fossil Fuel heating:

$$\Delta Therms = (((CFM50_existing - CFM50_new)/N_heat) * 60 * 24 * HDD * 0.018) / (\eta Heat * 100{,}000) * ADJ_{AirSealingFossilHeat} * IE_{NetCorrection} * \%FossilHeat$$

Where:

N_heat = Conversion factor from leakage at 50 Pascal to leakage at natural conditions

= Based on climate zone and building height:[1469]

Climate Zone (City based upon)	N_heat (by # of stories)			
	1	1.5	2	3
1 (Rockford)	23.8	21.1	19.3	17.1
2 (Chicago)	23.9	21.1	19.4	17.2
3 (Springfield)	24.2	21.5	19.7	17.4
4 (St Louis, MO)	25.4	22.5	20.7	18.3
5 (Paducah, KY)	27.8	24.6	22.6	20.0

HDD = Heating Degree Days

= dependent on location:[1470]

Climate Zone (City based upon)	HDD 60
1 (Rockford)	5230
2 (Chicago)	4798
3 (Springfield)	4266
4 (Belleville)	3188
5 (Marion/Murphysboro)	3390

ηHeat = Efficiency of heating system

= Equipment efficiency * distribution efficiency

= Actual (where it is possible to measure or reasonably estimate).[1471] Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per

[1469] N-factor is used to convert 50-pascal blower door air flows to natural air flows and is dependent on geographic location and # of stories. These were developed by applying the LBNL infiltration model (see LBNL paper 21040, *Exegisis of Proposed ASHRAE Standard 119: Air Leakage Performance for Detached Single-Family Residential Buildings*; Sherman, 1986; page v-vi, Appendix page 7-9) to the reported wind speeds and outdoor temperatures provided by the NRDC 30 year climate normals. For more information see Bruce Harley, CLEAResult "Infiltration Factor Calculations Methodology.doc". Note, the methodology for developing n-factors requires hourly normals as opposed to annual normals which are used for other assumptions in the TRM. Hourly normals were not available for all sites used for other climate assumptions and so the nearest locations were used (St Louis, MO for Belleville, IL and Paducah, KY for Marion, IL).

[1470] National Climatic Data Center, National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 60°F

[1471] Ideally, the System Efficiency should be obtained either by recording the AFUE of the unit, or performing a steady state efficiency test. The Distribution Efficiency can be estimated via a visual inspection and by referring to a look up table such as that provided by the Building Performance Institute: (see 'BPI Distribution Efficiency Table') or by performing duct blaster testing.

year (maximum of 30 years) to account for degradation over time,[1472] or if Equipment Efficiency is not available, use Section 5.3 to select the appropriate equipment efficiency for the project. If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85%.

$ADJ_{AirSealingFossilHeat}$ = Adjustment for fossil heating savings to account for inaccuracies in engineering algorithms:[1473]

Measure	$ADJ_{AirSealingFossilHeat}$
Air sealing and attic insulation	76%
Air sealing without attic insulation	100%

$IE_{NetCorrection}$ = 100% if not income eligible or air sealing is installed without attic insulation

= 110% if installing air sealing and attic insulation in income eligible projects with a deemed NTG value of 1.0 to offset net savings adjustment inherent when using $ADJ_{AirSealingFossilHeat}$ of 76%[1474]

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for Fossil Fuel heating

= 0 % for Electric Resistance or Heat Pump

= If unknown[1475], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[1476]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown

[1472] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1473] As demonstrated in air sealing and insulation research by Navigant, see Navigant (2018). C*omEd and Nicor Gas Air Sealing and Insulation Research Report.* Presented to Commonwealth Edison Company and Nicor Gas Company. These adjustment factors are based on a consumption data analysis using matching to non-participants. The values are therefore between net and gross with respect to free ridership. Like all consumption data analyses, they are net with respect to participant spillover and gross with respect to non-participant spillover. For more detail, see Table 5-3 in Volume 4 of the IL-TRM. Consistent with Section 7.2 of the Illinois EE Policy Manual, applicable net-to-gross adjustments to the savings will be determined as part of the annual SAG net-to-gross process. During update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all cooling-related adjustment values.

[1474] The additional value of 10% was selected to acknowledge that some portion of the regression-derived adjustment factors accounts for gross impact effects, and that removing net effects embedded in the adjustment factors would increase savings to some degree. A review of historical NTG values for air sealing and insulation measures in non-income eligible populations did not provide definitive guidance for estimating the net component of the adjustment factors. Historically, free ridership has ranged from 9% to 26% for like measures, and spillover has ranged from 1% to 14%, while NTGs have ranged from 0.75 to 1.05. The midpoint of the NTG range would be 0.90, a 10% reduction from 1.0.

[1475] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1476] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Other factors as defined above.

For example, energy savings from air sealing. Energy savings for attic insulation are included in a separate example in Section 5.6.5: Ceiling/Attic Insulation.

Assume a 2-story non-income eligible single family home in Chicago completes air sealing, installs attic insulation, has a gas furnace with system efficiency of 72%, and has pre and post blower door test results of 3,400 and 2,250 CFM:

ΔTherms = (((3,400 – 2,250)/19.4) * 60 * 24 * 4,798 * 0.018) / (0.72 * 100,000) * 76% * 100%
= 77.8 therms

Methodology 2: Prescriptive Infiltration Reduction Measures[1477]

Savings shall only be calculated via Methodology 2 when a blower door test is not conducted.

$$\Delta therms = (\Delta therms_{gasket} * n_{gasket} * ISR + \Delta therms_{windows} * sf_{windows} * ISR + \Delta therms_{sweep} * n_{sweep} * ISR + \Delta therms_{spray\ foam} * Oz_{spray\ foam} * ISR + \Delta therms_{sealing} * lf_{sealing} * ISR + \Delta therms_{WX} * lf_{WX} * ISR) * ADJ_{RxAirsealing}$$

Where:

$\Delta therms_{gasket}$ = Annual therm savings from installation of air sealing gasket on an electric outlet on an external wall.

Climate Zone (City based upon)	$\Delta therms_{gasket}$ / gasket Fossil Heat
1 (Rockford)	0.49
2 (Chicago)	0.47
3 (Springfield)	0.41
4 (Belleville)	0.33
5 (Marion)	0.33

n_{gasket} = Number of gaskets installed

$\Delta therms_{windows}$ = Annual therm savings from installation of Shrink-Fit Window Kit:[1478]

Climate Zone (City based upon)	$\Delta therms_{windows}$ / square ft Fossil Heat
1 (Rockford)	0.191
2 (Chicago)	0.183
3 (Springfield)	0.156
4 (Belleville)	0.121
5 (Marion)	0.123

[1477] Prescriptive savings are based upon "Evaluation of the Weatherization Residential Assistance Partnership and Helps Programs (WRAP/Helps)." Middletown, CT: KEMA, 2010. Accessed July 30, 2015, and adjusted for relative HDD of Bridgeport/Hartford CT with the IL climate zones. See 'Rx Airsealing HDD adjustment.xls' for more information.

[1478] Prescriptive savings are based upon "Cost Benefit Analysis for 2018, Annual Report submitted to Virginia Natural Gas, Inc., submitted by Nexant." July 31, 2018. Adjusted for relative HDD of Virginia Beach VA with the IL climate zones. See "Window Film Savings Calculation.xlsx" for more information.

$sf_{windows}$ = square footage of shrink-fit window film

$\Delta therms_{sweep}$ = Annual therm savings from installation of door sweep on a door between conditioned and unconditioned space

Climate Zone (City based upon)	$\Delta therms_{sweep}$ / sweep Fossil Heat
1 (Rockford)	9.46
2 (Chicago)	9.13
3 (Springfield)	7.92
4 (Belleville)	6.31
5 (Marion)	6.45

n_{sweep} = Number of sweeps installed

$\Delta therms_{spray\ foam}$ = Annual therm savings per ounce of spray foam product[1479]

= 1.65 therms per oz

NOTE: Saving assumptions for spray foam are Provisional.

$Oz_{spray\ foam}$ = Ounce of spray foam product

= Actual (default of 12oz for consumer product (or if unknown) or 20 oz for professional product)

$\Delta kWh_{sealing}$ = Annual kWh per linear foot savings from other air sealing products such as caulk, or polyethlylene tape in locations between conditioned and unconditioned space.

$\Delta therms_{sealing}$ = Annual therm per linear foot savings from other air sealing products such as caulk or polyethlylene tape in locations between conditioned and unconditioned space.

Climate Zone (City based upon)	$\Delta therms_{sealing}$ / linear ft Fossil Heat
1 (Rockford)	0.54
2 (Chicago)	0.52

[1479] Savings derived from Bibee et al., "Air Sealing Existing Homes with Foam-in-a-Can Rivals Energy Cost Benefits of CFLs", ASHRAE 2010.See "ASHRAE spray foam paper quick analysis_VEIC.xls" for details.

lf_{WX} = Linear feet of window weatherstripping or door weatherstripping

$ADJ_{RxAirsealing}$ = Adjustment for air sealing savings to account for prescriptive estimates overclaiming savings[1480]

= 80%

Other assumptions as defined above

Mid-Life adjustment

In order to account for the likely replacement of existing heating and cooling equipment during the life time of this measure, a mid-life adjustment should be applied. To calculate the adjustment, re-calculate the savings above using the following new baseline system efficiency assumptions:

Efficiency Assumption	System Type	New Baseline Efficiency
ηCool	Central AC (13.4 SEER2 * 0.85)	11.4 SEER2
	Heat Pump (14.3 SEER2 * 0.85)	12.2 SEER2
ηHeat	Electric Resistance (Baseboard or Electric Furnace)	1.0 COP
	Heat Pump (7.5HSPF/3.412)*0.85	1.87 COP
	Gas Furnace 80% AFUE * 0.85	68% AFUE
	Oil Furnace 83% AFUE * 0.85	71% AFUE
	Gas Boiler	84% AFUE
	Oil Boiler	86% AFUE

This reduced annual savings should be applied following the assumed remaining useful life of the existing equipment, estimate to be 10 years or 13 years for boilers.[1481] Note if the existing equipment efficiency is greater than the new baseline efficiency listed above, do not apply a mid-life adjustment.

WATER IMPACT DESCRIPTIONS AND CALCULATION

N/A

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

[1480] Though we do not have a specific evaluation to point to, modeled savings have often been found to overclaim. Further VEIC reviewed these deemed estimates and consider them to likely be a high estimate. As such an 80% adjustment is applied, and this could be further refined with future evaluations.

[1481] This is intentionally longer than the assumptions found in the early replacement measures as the application of this measure will occur in a variety of homes that will not be targeted for early replacement HVAC systems.

MEASURE CODE: RS-SHL-AIRS-V15-260101

REVIEW DEADLINE: 1/1/2027

5.6.2 Basement Sidewall Insulation

DESCRIPTION

Insulation is added to a basement or crawl space. Insulation added above ground in conditioned space is modeled the same as wall insulation. Below ground insulation is adjusted with an approximation of the thermal resistance of the ground. Insulation in semi-conditioned spaces is modeled by reducing the degree days to reflect the smaller but non-zero contribution to heating and cooling load. Cooling savings only consider above grade insulation, as below grade has little temperature difference during the cooling season.

A conditioned space is defined as a space within the thermal envelope[1482] of the building that is intentionally heated or cooled for occupancy (bedrooms, living room, bathrooms, kitchen, etc.). A non-conditioned space is defined as a space outside of the thermal envelope of the building that is not intentionally heated or cooled for occupancy. A semi-conditioned space is defined as a space within the thermal envelope that is not intentionally heated or cooled for occupancy (unfinished basement).

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure requires a member of the implementation staff or a participating contractor to evaluate the pre and post R-values and measure surface areas. The requirements for participation in the program will be defined by the utilities.

DEFINITION OF BASELINE EQUIPMENT

The existing condition will be evaluated by implementation staff or a participating contractor and is likely to be no basement wall or ceiling insulation.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 30 years.[1483]

Note a mid-life adjustment to account for replacement of HVAC equipment during the measure life should be applied after 10 years or 13 years for boilers.[1484] See section below for detail.

DEEMED MEASURE COST

The actual installed cost for this measure should be used in screening.

DEEMED O&M COST ADJUSTMENTS

N/A

LOADSHAPE

Loadshape R08 - Residential Cooling

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling

[1482] Thermal envelope refers to the shell of the building as a barrier to unwanted heat or mas transfer between the interior of the building and the outside conditions: IPCC, https://archive.ipcc.ch/publications_and_data/ar4/wg3/en/ch6s6-4-2.html

[1483] As recommended in Guidehouse 'EMV Group A, Deliverable 16 EUL Research – Residential Insulation', prepared for California Public Utilities Commission, June 2021.

[1484] This is intentionally longer than the assumptions found in the early replacement measures as the application of this measure will occur in a variety of homes that will not be targeted for early replacement HVAC systems.

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1485]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single family homes (during system peak hour)

= 72%[1486]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multifamily homes (during system peak hour)

= 67%[1487]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1488]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single family homes (average during PJM peak period)

= 46.6%[1489]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multifamily homes (average during peak period)

= 28.5%

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Where available savings from shell insulation measures should be determined through a custom analysis. When that is not feasible for the program the following engineering algorithms can be used with the inclusion of an adjustment factor to de-rate the heating savings.

$$\Delta kWh = (\Delta kWh_cooling + \Delta kWh_heatingElectric + \Delta kWh_heatingFurnace)$$

Where:

$\Delta kWh_cooling$ = If central cooling, reduction in annual cooling requirement due to insulation

[1485] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[1486] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[1487] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015
[1488] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1489] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

= ((((1/R_old_AG - 1/(R_added+R_old_AG)) * L_basement_wall_total * H_basement_wall_AG * (1-Framing_factor) * 24 * CDD * DUA * LoadFactor) / (1000 * ηCool)) * $ADJ_{BasementCool}$ * %Cool

R_added = R-value of additional spray foam, rigid foam, or cavity insulation.

R_old_AG = R-value value of foundation wall above grade.

= Actual, if unknown assume 1.0.[1490]

L_basement_wall_total = Length of basement wall around the entire insulated perimeter (ft)

H_basement_wall_AG = Height of insulated basement wall above grade (ft)

Framing_factor = Adjustment to account for area of framing when cavity insulation is used

= 0% if Spray Foam or External Rigid Foam

= 25% if studs and cavity insulation[1491]

24 = Converts hours to days

CDD = Cooling Degree Days

= Dependent on location and whether basement is conditioned, if unknown assume semi-conditioned:[1492]

Climate Zone (City based upon)	Conditioned CDD 65	Semi-Conditioned (CDD 75)[1493]
1 (Rockford)	877	326
2 (Chicago)	1047	354
3 (Springfield)	1183	448
4 (Belleville)	1641	532
5 (Marion)	1450	516
Weighted Average[1494]	1098	380

DUA = Discretionary Use Adjustment (reflects the fact that people do not always operate their AC when conditions may call for it).

= 0.90 [1495]

LoadFactor = Factor to reflect expected relative load (and therefore savings) or homes with Room AC

[1490] ORNL Builders Foundation Handbook, crawl space data from Table 5-5: Initial Effective R-values for Uninsulated Foundation System and Adjacent Soil, 1991.

[1491] ASHRAE, 2001, "Characterization of Framing Factors for New Low-Rise Residential Building Envelopes (904-RP)," Table 7.1

[1492] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 65°F. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[1493] Five year-average (2018 to 2022) cooling degree days with a base temperature of 75 F. Data from DegreeDays.net were used in this table because the climate normals from NCEI/NCDC used elsewhere are not available at base temps above 72F.

[1494] Weighted based on number of occupied residential housing units in each zone (US Census 2010).

[1495] This factor utilizes data from a metering study: Pigg, Scott, D. Cautley, and K. Koski, (2016): "Improving Installation and Maintenance Practices for Minnesota Residential Furnaces, Air Conditioners, and Heat Pumps", prepared for Minnesota Department of Commerce, Division of Energy. COMM-201305222-72623. To correct for the different climatological conditions in Minnesota and Illinois, the analysis includes 19 homes that have actual annual operating hours above 453 hrs/yr (over ½ of the actual annual operating hours for the highest operating hours home in the study-905 hrs/yr). Additionally, the factor is adjusted from 0.87 to 0.90 to account for Illinois' hotter climate and higher number of muggy days. See DUA_Workbook_051525.xlsx for detailed data.

v Central AC.

= 1.0 for homes with central AC, 0.41 for homes with Room AC[1496]

1000 = Converts Btu to kBtu

ηCool = Efficiency (SEER2 or CEER) of cooling system (kBtu/kWh) * Distribution Efficiency

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for central cooling with ducts if only equipment efficiency is available). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1497] or if unknown assume the following.[1498] If unknown value is used, it should not be derated by age.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3
Room AC[1499]		
Non-IQ	10.9	10.9
IQ	9.7	9.7
Unknown (for use in program evaluation only)[1500]		
Single Family Non-IQ		10.6
Single Family IQ		10.3
Multi Family Non-IQ		10.3
Multi Family IQ		9.9
Unknown		10.3

$ADJ_{BasementCool}$ = Adjustment for cooling savings from basement wall insulation to account for prescriptive engineering algorithms overclaiming savings[1501]

[1496] Based upon review of 102 room AC replacement projects completed in 2023 and 2024 for an Illinois multifamily energy efficiency program, the average room AC capacity installed was 11.41 MBh per living unit. From Section 5.3.3 for Central Air Conditioning, default central A/C capacity is 28 MBh. This results in a capacity scale factor of 11.41 / 28 = 0.41 when using room air conditioner cooling.

[1497] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1498] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

[1499] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[1500] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1501] As demonstrated in two years of metering evaluation by Opinion Dynamics, see Memo "Results for AIC PY6 HPwES Billing Analysis", dated February 20, 2015. TAC negotiated adjustment factor is 80%. During update cycle for version v.12, applied the percent change of NCEI Annual Normals CDD65 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all cooling-related adjustment values.

= 75%

%Cool = Percent of homes that have cooling

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[1502]	98.9%	96.5%	99.8%	98.7%	98.6%

ΔkWh_heatingElectric = If electric heat (resistance baseboard, electric furnace or heat pump), reduction in annual electric heating due to insulation

= [(((1/R_old_AG - 1/(R_added+R_old_AG)) * L_basement_wall_total * H_basement_wall_AG * (1-Framing_factor)) + ((1/R_old_BG - 1/(R_added+R_old_BG)) * L_basement_wall_total * (H_basement_wall_total - H_basement_wall_AG) * (1-Framing_factor))] * 24 * HDD) / (3,412 * ηHeat)) * $ADJ_{BasementHeat}$ *%ElectricHeat

Where:

R_old_BG = R-value value of foundation wall below grade (including thermal resistance of the earth) [1503]

= Actual R-value of wall plus Average Earth R-value from table below

= dependent on depth of foundation (H_basement_wall_total – H_basement_wall_AG):

= Actual R-value of wall plus average earth R-value by depth in table below

Below Grade R-value									
Depth below grade (ft)	0	1	2	3	4	5	6	7	8
Earth R-value (°F-ft^2-h/Btu)	2.44	4.50	6.30	8.40	10.44	12.66	14.49	17.00	20.00
Average Earth R-value (°F-ft2-h/Btu)	2.44	3.47	4.41	5.41	6.42	7.46	8.46	9.53	10.69
Total BG R-value (earth + R-1.0 foundation) default	3.44	4.47	5.41	6.41	7.42	8.46	9.46	10.53	11.69

H_basement_wall_total = Total height of basement wall (ft)

HDD = Heating Degree Days

= dependent on location and whether basement is conditioned, if unknown assume semi-conditioned:[1504]

[1502] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.
[1503] Adapted from Table 1, page 24.4, of the 1977 ASHRAE Fundamentals Handbook
[1504] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 60°F for a conditioned basement and 50°F for an unconditioned basement), consistent with the findings of Belzer and Cort, Pacific Northwest National Laboratory in "Statistical Analysis of Historical State-Level Residential Energy Consumption Trends," 2004. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

Climate Zone (City based upon)	Conditioned HDD 60	Semi-Conditioned HDD 50
1 (Rockford)	5230	3233
2 (Chicago)	4798	2845
3 (Springfield)	4266	2456
4 (Belleville)	3188	1651
5 (Marion/Murphysboro)	3390	1750
Weighted Average[1505]	4631	2732

ηHeat = Efficiency of heating system

= Actual (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1506] or if not available refer to default table below.[1507] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85% for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) (HSPF2/3.412)*0.85
Heat Pump (if age unknown, assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 -2014	6.5	1.62
	2015 on	7	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1
Unknown (for use in program evaluation only)	N/A	N/A	1.32

$ADJ_{BasementHeat}$ = Adjustment for basement wall insulation to account for prescriptive engineering algorithms overclaiming savings[1508]

= 63%

[1505] Weighted based on number of occupied residential housing units in each zone.

[1506] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1507] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

[1508] TAC negotiated factor of 60% was originally proposed, then, during update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all cooling-related adjustment values.

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= 0 % for Fossil fuel heating

= If unknown[1509], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[1510]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

For example, a single family home in Chicago with a 20 by 25 by 7 foot R-2.25 semi-conditioned basement, with 3 feet above grade, insulated with R-13 of interior spray foam, 10.5 SEER Central AC and 2.26 (1.92 including distribution losses) COP Heat Pump:

ΔkWh = (ΔkWh_cooling + ΔkWh_heating)

= [(((1/2.25 - 1/(13 + 2.25))*(20+25+20+25) * 3 * (1 - 0)) * 24 * 354 * 0.90)/(1000 * 10.5)) * 0.75 * 100%] + [((((1/2.25 - 1/(13 + 2.25)) * (20+25+20+25) * 3 * (1-0)) + ((1 / (2.25 + 6.42) – 1 / (13 + 2.25 + 6.42)) * (20+25+20+25) * 4 * (1-0))) * 24 * 2845) / (3412 * 1.92)) * 0.63 * 100%]

= (55.8 + 835.3)

= 891.1 kWh

ΔkWh_heatingFurnace = If *furnace* (fossil fueled or electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = ΔTherms * F_e * 29.3

If electric furnace: = ΔkWh_heatingElectric * F_e

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[1511]

[1509] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1510] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[1511] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample

29.3 = kWh per therm

For example, a single family home in Chicago with a 20 by 25 by 7 foot unconditioned basement, with 3 feet above grade, insulated with R-13 of interior spray foam, and a 70% efficient furnace (for therm calculation see Fossil Fuel Savings section :

= 76.0 * 0.0314 * 29.3

= 69.9 kWh

SUMMER COINCIDENT PEAK DEMAND

ΔkW = (ΔkWh_cooling / FLH_cooling) * CF

Where:

FLH_cooling = Full load hours of air conditioning

= dependent on location:[1512]

Climate Zone (City based upon)	Single Family	Multifamily		
	Conditioned	Semi-Conditioned[1513]	Conditioned	Semi-Conditioned
1 (Rockford)	547	203	499	185
2 (Chicago)	709	240	629	213
3 (Springfield)	779	295	707	268
4 (Belleville)	1082	351	982	318
5 (Marion)	956	340	868	309
Weighted Average[1514]				
ComEd	676	234	603	209
Ameren	875	303	791	274
Statewide	731	253	655	227

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or room A/C (during utility peak hour)

= 68%[1515]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

(non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[1512] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[1513] Semi-Conditioned are estimated based on the ratio of CDD between conditioned and semi-conditioned spaces.

[1514] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[1515] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

= 72%[1516]

$CF_{SSP, MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[1517]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or room A/C (average during PJM peak period)

= 46.6%[1518]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1519]

$CF_{PJM, MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

For example, a single family home in Chicago with a 20 by 25 by 7 foot semi-conditioned basement, with 3 feet above grade, insulated with R-13 of interior spray foam, 10.5 SEER Central AC and 2.26 COP Heat Pump:

ΔkW_{SSP} = 55.8 / 240* 0.68

= 0.158 kW

ΔkW_{PJM} = 55.8 / 240 * 0.466

= 0.108 kW

FOSSIL FUEL SAVINGS

If Fossil Fuel heating:

ΔTherms = (((((1/R_old_AG - 1/(R_added+R_old_AG)) * L_basement_wall_total * H_basement_wall_AG * (1-Framing_factor)) + ((1/R_old_BG - 1/(R_added+R_old_BG)) * L_basement_wall_total * (H_basement_wall_total - H_basement_wall_AG) * (1-Framing_factor))) * 24 * HDD) / (ηHeat * 100,000)) * $ADJ_{BasementHeat}$ * %FossilHeat

ηHeat = Efficiency of heating system

= Equipment efficiency * distribution efficiency

= Actual (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1520] or if unknown assume

[1516] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[1517] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

[1518] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1519] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1520] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

72% for existing system efficiency[1521]. If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85%.

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for Fossil Fuel heating

= 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= If unknown[1522], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[1523]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Other factors as defined above

For example, a single family home in Chicago with a 20 by 25 by 7 foot R-2.25 basement, with 3 feet above grade, insulated with R-13 of interior spray foam, and a 72% efficient furnace:

= (((((1/2.25 - 1/(13 + 2.25)) * (20+25+20+25) * 3 * (1-0)) + ((1/8.67 - 1/(13 + 8.67)) * (20+25+20+25) * 4 * (1 - 0))) * 24 * 2845) / (0.72 * 100,000)) * 0.63 * 100%

= 76.0 therms

Mid-Life adjustment

In order to account for the likely replacement of existing heating and cooling equipment during the lifetime of this measure, a mid-life adjustment should be applied. To calculate the adjustment, re-calculate the savings above using the following new baseline system efficiency assumptions:

Efficiency Assumption	System Type	New Baseline Efficiency
ηCool	Central AC (13.4 SEER2 * 0.85)	11.4 SEER2
	Heat Pump (14.3 SEER2 * 0.85)	12.2 SEER2
ηHeat	Electric Resistance (Baseboard or Electric Furnace)	1.0 COP

[1521] Based on average Nicor PY4 nameplate efficiencies derated by 15% for distribution losses.

[1522] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1523] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

Efficiency Assumption	System Type	New Baseline Efficiency
	Heat Pump (7.5HSPF/3.412)*0.85	1.87 COP
	Gas Furnace 80% AFUE * 0.85	68% AFUE
	Oil Furnace 83% AFUE * 0.85	71% AFUE
	Gas Boiler	84% AFUE
	Oil Boiler	86% AFUE

This reduced annual savings should be applied following the assumed remaining useful life of the existing equipment, estimate to be 10 years or 13 years for boilers.[1524] Note if the existing equipment efficiency is greater than the new baseline efficiency listed above, do not apply a mid-life adjustment.

DEEMED O&M COST ADJUSTMENT CALCULATION

N/A

MEASURE CODE: RS-SHL-BINS-V16-260101

REVIEW DEADLINE: 1/1/2030

[1524] This is intentionally longer than the assumption found in the early replacement measures as the application of this measure will occur in a variety of homes and will not be targeting those homes appropriate for early replacement HVAC systems.

5.6.3 Floor Insulation Above Crawlspace

DESCRIPTION

Insulation is added to the floor above a vented crawl space that does not contain pipes or HVAC equipment. If there are pipes, HVAC, or a basement, it is desirable to keep them within the thermal envelope by insulating the crawl space walls and ground. Insulating the floor separates the conditioned space above from the space below the floor, and is only acceptable when there is nothing underneath that could freeze or would operate less efficiently in an environment resembling the outdoors. Even in the case of an empty, unvented crawl space, it is still considered best practice to seal and insulate the crawl space perimeter rather than the floor. Not only is there generally less area to insulate this way, but there are also moisture control benefits. There is a "Basement Insulation" measure for perimeter sealing and insulation. This measure assumes the insulation is installed above an vented crawl space and should not be used in other situations.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure requires a member of the implementation staff or a participating contractor to evaluate the pre and post R-values and measure surface areas. The requirements for participation in the program will be defined by the utilities.

DEFINITION OF BASELINE EQUIPMENT

The existing condition will be evaluated by implementation staff or a participating contractor and is likely to be no insulation on any surface surrounding a crawl space.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 30 years.[1525]

Note a mid-life adjustment to account for replacement of HVAC equipment during the measure life should be applied after 10 years or 13 years for boilers.[1526] See section below for detail.

DEEMED MEASURE COST

The actual installed cost for this measure should be used in screening.

DEEMED O&M COST ADJUSTMENTS

LOADSHAPE

Loadshape R08 - Residential Cooling

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's

[1525] As recommended in Guidehouse 'EMV Group A, Deliverable 16 EUL Research – Residential Insulation', prepared for California Public Utilities Commission, June 2021.

[1526] This is intentionally longer than the assumptions found in the early replacement measures as the application of this measure will occur in a variety of homes that will not be targeted for early replacement HVAC systems.

capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1527]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single family homes (during system peak hour)

= 72%[1528]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multifamily homes (during system peak hour)

= 67%[1529]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1530]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single family homes (average during PJM peak period)

= 46.6%[1531]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multifamily homes (average during peak period)

= 28.5%

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Where available savings from shell insulation measures should be determined through a custom analysis. When that is not feasible for the program the following engineering algorithms can be used with the inclusion of an adjustment factor to de-rate the heating savings.

ΔkWh = (ΔkWh_cooling + ΔkWh_ heatingElectric + ΔkWh_heatingFurnace)

Where:

ΔkWh_cooling = If central cooling, reduction in annual cooling requirement due to insulation

= ((((1/R_old - 1/(R_added+R_old)) * Area * (1-Framing_factor)) * 24 * CDD * DUA * LoadFactor) / (1000 * ηCool))) * $ADJ_{FloorCool}$ * %Cool

R_old = R-value value of floor before insulation, assuming 3/4" plywood subfloor and carpet with pad

[1527] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[1528] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[1529] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015
[1530] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1531] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

= Actual. If unknown assume 3.53 for site built homes [1532] and 2.61 for mobile homes[1533]

R_added= R-value of additional spray foam, rigid foam, or cavity insulation.

Area = Total floor area to be insulated

Framing_factor = Adjustment to account for area of framing

= 12% for site built homes[1534]

= 0 for mobile home belly wrap insulation

24 = Converts hours to days

CDD = Cooling Degree Days

Climate Zone (City based upon)	Conditioned CDD65[1535]
1 (Rockford)	877
2 (Chicago)	1047
3 (Springfield)	1183
4 (Belleville)	1641
5 (Marion)	1450
Weighted Average[1536]	1098

DUA = Discretionary Use Adjustment (reflects the fact that people do not always operate their AC when conditions may call for it).

= 0.90 [1537]

LoadFactor = Factor to reflect expected relative load (and therefore savings) or homes with Room AC v Central AC.

= 1.0 for homes with central AC, 0.41 for homes with Room AC[1538]

1000 = Converts Btu to kBtu

ηCool = Efficiency (SEER2 or CEER) of cooling system (kBtu/kWh) * Distribution Efficiency

[1532] Based on 2005 ASHRAE Handbook – Fundamentals: assuming ¾" subfloor, ½" carpet with rubber pad, and accounting for a still air film above and below: 0.68 + 0.94 + 1.23 + 0.68 = 3.53

[1533] Based on 2017 ASHRAE Handbook – Fundamentals: assuming a composite of 4 layers: 1) still indoor air film above floor system (0.68), 2) blended floor covering (r=0.935): 25% tile/linoleum (r=0.05) and 75% ½"carpet with rubber pad (r=1.23), 3) 5/8" particle board subflooring (r=0.82), and 4) exterior air film (0.17): 0.68 + 0.935 + 0.82 + 0.17 = 2.61.

[1534] ASHRAE, 2001, "Characterization of Framing Factors for New Low-Rise Residential Building Envelopes (904-RP)," Table 7.1

[1535] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 65°F. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[1536] Weighted based on number of occupied residential housing units in each zone (US Census 2010).

[1537] This factor utilizes data from a metering study: Pigg, Scott, D. Cautley, and K. Koski, (2016): "Improving Installation and Maintenance Practices for Minnesota Residential Furnaces, Air Conditioners and Heat Pumps", prepared for Minnesota Department of Commerce, Division of Energy. COMM-201305222-72623. To correct for the different climatological conditions in Minnesota and Illinois, the analysis includes 19 homes that have actual annual operating hours above 453 hrs/yr (over ½ of the actual annual operating hours for the highest operating hours home in the study-905 hrs/yr). Additionally, the factor is adjusted from 0.87 to 0.90 to account for Illinois' hotter climate and higher number of muggy days. See DUA_Workbook_051525.xlsx for detailed data.

[1538] Based upon review of 102 room AC replacement projects completed in 2023 and 2024 for an Illinois multifamily energy efficiency program, the average room AC capacity installed was 11.41 MBh per living unit. From Section 5.3.3 for Central Air Conditioning, default central A/C capacity is 28 MBh. This results in a capacity scale factor of 11.41 / 28 = 0.41 when using room air conditioner cooling.

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for central cooling with ducts if only equipment efficiency is available). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1539] or if unknown assume the following.[1540] If unknown value is used, it should not be derated by age.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3
Room AC[1541]		
Non-IQ	10.9	10.9
IQ	9.7	9.7
Unknown (for use in program evaluation only)[1542]		
Single Family Non-IQ		10.6
Single Family IQ		10.3
Multi Family Non-IQ		10.3
Multi Family IQ		9.9
Unknown		10.3

$ADJ_{FloorCool}$ = Adjustment for cooling savings from floor to account for prescriptive engineering algorithms overclaiming savings[1543]

= 75%

%Cool = Percent of homes that have cooling

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				

[1539] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1540] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

[1541] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[1542] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1543] As demonstrated in two years of metering evaluation by Opinion Dynamics, see Memo "Results for AIC PY6 HPwES Billing Analysis", dated February 20, 2015. TAC negotiated adjustment factor is 80%. During update cycle for version v.12, applied the percent change of NCEI Annual Normals CDD65 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all cooling-related adjustment values.

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Unknown (for use in program evaluation only)[1544]	98.9%	96.5%	99.8%	98.7%	98.6%

ΔkWh_heatingElectric = If electric heat (resistance baseboard, electric furnace or heat pump), reduction in annual electric heating due to insulation

= (((1/R_old - 1/(R_added + R_old)) * Area * (1-Framing_factor) * 24 * HDD)/ (3,412 * ηHeat)) * $ADJ_{FloorHeat}$ *%ElectricHeat

HDD = Heating Degree Days:[1545]

Climate Zone (City based upon)	Conditioned HDD 60
1 (Rockford)	5230
2 (Chicago)	4798
3 (Springfield)	4266
4 (Belleville)	3188
5 (Marion/Murphysboro)	3390
Weighted Average[1546]	4631

ηHeat = Efficiency of heating system

= Actual Heating Efficiency * Distribution Efficiency (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1547] or if not available refer to default table below.[1548] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85%.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) (HSPF2/3.412)*0.85
Heat Pump (if age unknown, assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 -2014	6.5	1.62
	2015 on	7	1.74

[1544] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.
[1545] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 50°F to account for lower impact of unconditioned space on heating system. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.
[1546] Weighted based on number of occupied residential housing units in each zone.
[1547] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).
[1548] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) (HSPF2/3.412)*0.85
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1
Unknown (for use in program evaluation only)	N/A	N/A	1.32

$ADJ_{FloorHeat}$ = Adjustment for floor insulation to account for prescriptive engineering algorithms overclaiming savings[1549]

= 63%

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= 0 % for Fossil Fuel heating

= If unknown[1550], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[1551]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Other factors as defined above.

[1549] As demonstrated in two years of metering evaluation by Opinion Dynamics, see Memo "Results for AIC PY6 HPwES Billing Analysis", dated February 20, 2015. TAC negotiated adjustment factor is 60%. During update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all heating-related adjustment values.

[1550] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1551] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

For example, a single family home in Chicago with a 20 by 25 footprint, insulated with R-30 spray foam above the crawlspace, a 10.5 SEER Central AC and a newer heat pump:

ΔkWh = (ΔkWh_cooling + ΔkWh_heating)

= ((((1/3.53 -1/(30+3.53))*(20*25)*(1-0.12)* 24 * 1047*0.90)/(1000*10.5)) * 0.75 * 1 + (((1/3.53 -1/(30+3.53))*(20*25)*(1-0.15) * 24 * 4798)/(3412*1.92)) * 0.63 * 1)

= (181.7 + 1192.9)

= 1374.6 kWh

ΔkWh_heatingFurnace = If *furnace* (fossil fuel and electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = ΔTherms * F_e * 29.3

If electric furnace: = ΔkWh_heatingElectric * F_e

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[1552]

29.3 = kWh per therm

For example, a single family home in Chicago with a 20 by 25 footprint, insulated with R-30 spray foam above the crawlspace, and a 70% efficient gas furnace (for therm calculation see Fossil Fuel Savings section):

ΔkWh = 66.6 * 0.0314 * 29.3

= 61.3 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = (ΔkWh_cooling / FLH_cooling) * CF

Where:

FLH_cooling = Full load hours of air conditioning

= Dependent on location:[1553]

Climate Zone (City based upon)	Single Family	Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1082	982
5 (Marion)	956	868

[1552] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[1553] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

Climate Zone (City based upon)	Single Family	Multifamily
Weighted Average[1554]		
ComEd	676	603
Ameren	875	791
Statewide	731	655

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[1555]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single family homes (during system peak hour)

= 72%[1556]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multifamily homes (during system peak hour)

= 67%[1557]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[1558]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single family homes (average during PJM peak period)

= 46.6%[1559]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multifamily homes (average during peak period)

= 28.5%

For example, a single family home in Chicago with a 20 by 25 footprint, insulated with R-30 spray foam above the crawlspace, a 10.5 SEER Central AC and a newer heat pump:

ΔkW_{SSP} = 181.7 / 709 * 0.68

= 0.058 kW

ΔkW_{SSP} = 60.9 / 709 * 0.466

= 0.040 kW

[1554] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[1555] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[1556] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[1557] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

[1558] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1559] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

FOSSIL FUEL SAVINGS

If Fossil Fuel heating:

$$\Delta Therms = (((1/R_old - 1/(R_added+R_old)) * Area * (1-Framing_factor) * 24 * HDD) / (100{,}000 * \eta Heat)) * ADJ_{FloorHeat} * \%FossilHeat$$

Where:

ηHeat = Efficiency of heating system

= Equipment efficiency * distribution efficiency

= Actual (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1560] or if unknown assume 72% for existing system efficiency.[1561] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85%.

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for Fossil Fuel heating

= 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= If unknown[1562], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[1563]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Other factors as defined above.

[1560] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1561] Based on average Nicor PY4 nameplate efficiencies derated by 15% for distribution losses.

[1562] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1563] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

For example, a single family home in Chicago with a 20 by 25 footprint, insulated with R-30 spray foam above the crawlspace, and a 72% efficient furnace:

$$\Delta Therms = ((1 / 3.53 – 1 /(30 + 3.53))*(20 * 25) * (1 - 0.12) * 24 * 2845) / (100{,}000 * 0.72) * 0.63 * 1$$

$$= 66.6 \text{ therms}$$

Mid-Life adjustment

In order to account for the likely replacement of existing heating and cooling equipment during the lifetime of this measure, a mid-life adjustment should be applied. To calculate the adjustment, re-calculate the savings above using the following new baseline system efficiency assumptions:

Efficiency Assumption	System Type	New Baseline Efficiency
ηCool	Central AC (13.4 SEER2 * 0.85)	11.4 SEER2
	Heat Pump (14.3 SEER2 * 0.85)	12.2 SEER2
ηHeat	Electric Resistance (Baseboard or Electric Furnace)	1.0 COP
	Heat Pump (7.5HSPF/3.412)*0.85	1.87 COP
	Gas Furnace 80% AFUE * 0.85	68% AFUE
	Oil Furnace 83% AFUE * 0.85	71% AFUE
	Gas Boiler	84% AFUE
	Oil Boiler	86% AFUE

This reduced annual savings should be applied following the assumed remaining useful life of the existing equipment, estimate to be 10 years or 13 years for boilers.[1564] Note if the existing equipment efficiency is greater than the new baseline efficiency listed above, do not apply a mid-life adjustment.

MEASURE CODE: RS-SHL-FINS-V18-260101

REVIEW DEADLINE: 1/1/2030

[1564] This is intentionally longer than the assumption found in the early replacement measures as the application of this measure will occur in a variety of homes and will not be targeting those homes appropriate for early replacement HVAC systems.

5.6.4 Wall Insulation

DESCRIPTION

Insulation is added to wall cavities. This measure requires a member of the implementation staff evaluating the pre and post R-values and measure surface areas. The efficiency of the heating and cooling equipment in the home should also be evaluated if possible.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure requires a member of the implementation staff or a participating contractor to evaluate the pre and post R-values and measure surface areas. The requirements for participation in the program will be defined by the utilities.

DEFINITION OF BASELINE EQUIPMENT

The existing condition will be evaluated by implementation staff or a participating contractor and is likely to be empty wall cavities.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 30 years.[1565]

Note a mid-life adjustment to account for replacement of HVAC equipment during the measure life should be applied after 10 years or 13 years for boilers.[1566] See section below for detail.

DEEMED MEASURE COST

The actual installed cost for this measure should be used in screening.

LOADSHAPE

Loadshape R08 - Residential Cooling

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1567]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single family homes (during system peak hour)

[1565] As recommended in Guidehouse 'EMV Group A, Deliverable 16 EUL Research – Residential Insulation', prepared for California Public Utilities Commission, June 2021.

[1566] This is intentionally longer than the assumptions found in the early replacement measures as the application of this measure will occur in a variety of homes that will not be targeted for early replacement HVAC systems.

[1567] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

= 72%[1568]

$CF_{SSP, MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multifamily homes (during system peak hour)

= 67%[1569]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1570]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single family homes (average during PJM peak period)

= 46.6%[1571]

$CF_{PJM, MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multifamily homes (average during peak period)

= 28.5%

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Where available savings from shell insulation measures should be determined through a custom analysis. When that is not feasible for the program the following engineering algorithms can be used with the inclusion of an adjustment factor to de-rate the heating savings.

ΔkWh = ΔkWh_cooling + ΔkWh_heatingElectric + ΔkWh_heatingFurnace

Where

ΔkWh_cooling = If central cooling, reduction in annual cooling requirement due to wall insulation

= ((((1/R_old - 1/R_wall) * A_wall * (1-Framing_factor_wall)) * 24 * CDD * DUA * LoadFactor) / (1000 * ηCool)) * $ADJ_{WallCool}$* %Cool

R_wall = R-value of new wall assembly (including all layers between inside air and outside air).

R_old = R-value value of existing assembly and any existing insulation.

(Minimum of R-5 for uninsulated assemblies)[1572]

A_wall = Net area of insulated wall (ft^2)

Framing_factor_wall = Adjustment to account for area of framing

= 25%[1573]

[1568] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[1569] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

[1570] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1571] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1572] An estimate based on review of Madison Gas and Electric, Exterior Wall Insulation, R-value for no insulation in walls, and NREL's Building Energy Simulation Test for Existing Homes (BESTEST-EX).

[1573] ASHRAE, 2001, "Characterization of Framing Factors for New Low-Rise Residential Building Envelopes (904-RP)," Table 7.1

24 = Converts hours to days

CDD = Cooling Degree Days

= dependent on location:[1574]

Climate Zone (City based upon)	CDD 65
1 (Rockford)	877
2 (Chicago)	1047
3 (Springfield)	1183
4 (Belleville)	1641
5 (Marion)	1450
Weighted Average[1575]	1098

DUA = Discretionary Use Adjustment (reflects the fact that people do not always operate their AC when conditions may call for it).

= 0.90 [1576]

LoadFactor = Factor to reflect expected relative load (and therefore savings) or homes with Room AC v Central AC.

= 1.0 for homes with central AC, 0.41 for homes with Room AC[1577]

1000 = Converts Btu to kBtu

ηCool = Efficiency (SEER2 or CEER) of cooling system (kBtu/kWh) * Distribution Efficiency

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for central cooling with ducts if only equipment efficiency is available). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1578] or if unknown assume the following.[1579] If unknown value is used, it should not

[1574] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 65°F. There is a county mapping table Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.
[1575] Weighted based on number of occupied residential housing units in each zone (US Census 2010).
[1576] This factor utilizes data from a metering study: Pigg, Scott, D. Caultlet, and K. Koski, (2016): "Improving Installation and Maintenace Practices for Minnesota Residentail Furnaces, Air Conditioners and Heat Pumps", prepared for Minnestora Department of Commerce, Division of Energy. COMM-201305222-72623. To correct for the different climatological conditions in Minnesota and Illinois, the analysis includes 19 homes that have actual annual operating hours above 453 hrs/yr (over 1/2 of the actual annual operating hours for the highest operating hours home in the study-905 hrs/yr). Additionally, the factor is adjusted from 0.87 to 0.90 to account for Illinois' hotter climate and higher number of muggy days. See DUA_Workbook_051525.xlsx for detailed data.
[1577] Based upon review of 102 room AC replacement projects completed in 2023 and 2024 for an Illinois multifamily energy efficiency program, the average room AC capacity installed was 11.41 MBh per living unit. From Section 5.3.3 for Central Air Conditioning, default central A/C capacity is 28 MBh. This results in a capacity scale factor of 11.41 / 28 = 0.41 when using room air conditioner cooling.
[1578] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).
[1579] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. Note all ratings have been

be derated by age.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3
Room AC[1580]		
Non-IQ	10.9	10.9
IQ	9.7	9.7
Unknown (for use in program evaluation only)[1581]		
Single Family Non-IQ		10.6
Single Family IQ		10.3
Multi Family Non-IQ		10.3
Multi Family IQ		9.9
Unknown		10.3

$ADJ_{WallCool}$ = Adjustment for cooling savings from wall insulation to account for inaccuracies in prescriptive engineering algorithms[1582]

= 75%

%Cool = Percent of homes that have cooling

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[1583]	98.9%	96.5%	99.8%	98.7%	98.6%

kWh_heatingElectric = If electric heat (resistance baseboard, electric furnace or heat pump), reduction in annual electric heating due to wall insulation

= (((1/R_old - 1/R_wall) * A_wall * (1-Framing_factor_wall) * 24 * HDD) / (ηHeat * 3412)) * $ADJ_{WallHeat}$ * %ElectricHeat

HDD = Heating Degree Days

converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

[1580] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[1581] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1582] As demonstrated in two years of metering evaluation by Opinion Dynamics, see Memo "Results for AIC PY6 HPwES Billing Analysis", dated February 20, 2015. TAC negotiated adjustment factor is 80%. During update cycle for version v.12, applied the percent change of NCEI Annual Normals CDD65 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all cooling-related adjustment values.

[1583] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

= Dependent on location:[1584]

Climate Zone (City based upon)	HDD 60
1 (Rockford)	5230
2 (Chicago)	4798
3 (Springfield)	4266
4 (Belleville)	3188
5 (Marion)	3390
Weighted Average[1585]	4631

ηHeat = Efficiency of heating system

= Actual Heating Efficiency * Distribution Efficiency (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1586] or if not available refer to default table below.[1587] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85% for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) (HSPF2/3.412)*0.85
Heat Pump (if age unknown, assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 -2014	6.5	1.62
	2015 on	7	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1
Unknown (for use in program evaluation only)	N/A	N/A	1.32

3412 = Converts Btu to kWh

$ADJ_{WallHeat}$ = Adjustment for heating savings to account for inaccuracies in prescriptive engineering algorithms. [1588]

[1584] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 60°F, consistent with the findings of Belzer and Cort, Pacific Northwest National Laboratory in "Statistical Analysis of Historical State-Level Residential Energy Consumption Trends," 2004. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[1585] Weighted based on number of occupied residential housing units in each zone.

[1586] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1587] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

[1588] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate

= 63%

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= 0 % for Fossil Fuel heating

= If unknown[1589], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[1590]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

For example, a single family home in Chicago with 990 ft^2 of R-5 walls insulated to R-11, 10.5 SEER Central AC and 2.26 (1.92 including distribution losses) COP Heat Pump:

ΔkWh = (ΔkWh_cooling + ΔkWh_heating)

= (((((1/5 - 1/11) * 990 * (1-0.25)) * 1,047 * 0.90 * 24)/ (1,000 * 10.5)) * 75% * 100%) + (((((1/5 - 1/11) * 990 * (1-0.25)) * 4,798 * 24) / (1.92 * 3,412)) * 63% * 100%)

= 130.8 + 897

ΔkWh_heatingFurnace = If *furnace* (fossil fueled or electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = ΔTherms * F_e * 29.3

If electric furnace: = ΔkWh_heatingElectric * F_e

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[1591]

efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1588] TAC negotiated adjustment factor was 60%. During update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all heating-related adjustment values.

[1589] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1590] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[1591] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

29.3 = kWh per therm

For example, a single family home in Chicago with 990 ft^2 of R-5 walls insulated to R-11 with a gas furnace with system efficiency of 66% (for therm calculation see Fossil Fuel Savings section):

ΔkWh_heatingGas = 89.0 * 0.0314 * 29.3

= 81.9 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = (ΔkWh_cooling / FLH_cooling) * CF

Where:

FLH_cooling = Full load hours of air conditioning

= Dependent on location as below:[1592]

Climate Zone (City based upon)	Single Family	Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1082	982
5 (Marion)	956	868
Weighted Average[1593]		
ComEd	676	603
Ameren	875	791
Statewide	731	655

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[1594]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single family homes (during system peak hour)

= 72%[1595]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multifamily homes (during system peak hour)

[1592] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[1593] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[1594] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[1595] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

= 67%[1596]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[1597]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single family homes (average during PJM peak period)

= 46.6%[1598]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multifamily homes (average during peak period)

= 28.5%

For example, a single family home in Chicago with 990 ft^2 of R-5 walls insulated to R-11, 10.5 SEER Central AC, and 2.26 COP Heat Pump:

ΔkW_{SSP} = 130.8 / 709 * 0.68

= 0.1250 kW

ΔkW_{PJM} = 130.8 / 709 * 0.466

= 0.086 kW

FOSSIL FUEL SAVINGS

If Fossil Fuel heating:

ΔTherms = (((1/R_old - 1/R_wall) * A_wall * (1-Framing_factor_wall) * 24 * HDD) / (ηHeat * 100,000 Btu/therm)) * $ADJ_{WallHeat}$* %FossilHeat

Where:

HDD = Heating Degree Days

= Dependent on location:[1599]

Climate Zone (City based upon)	HDD 60
1 (Rockford)	5230
2 (Chicago)	4798
3 (Springfield)	4266
4 (Belleville)	3188
5 (Marion)	3390
Weighted Average[1600]	4631

[1596] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

[1597] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1598] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1599] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 60°F, consistent with the findings of Belzer and Cort, Pacific Northwest National Laboratory in "Statistical Analysis of Historical State-Level Residential Energy Consumption Trends," 2004. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[1600] Weighted based on number of occupied residential housing units in each zone (US Census 2010).

ηHeat = Efficiency of heating system

= Equipment efficiency * distribution efficiency

= Actual (where it is possible to measure or reasonably estimate).[1601] Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1602] or if unknown assume 72% for existing system efficiency.[1603] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85%.

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for Fossil Fuel heating

= 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= If unknown[1604], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[1605]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Other factors as defined above.

For example, a single family home in Chicago with 990 ft^2 of R-5 walls insulated to R-11, with a gas furnace with system efficiency of 66%:

ΔTherms = ((((1/5 - 1/11) * 990 * (1-0.25)) * 24 * 4798) / (0.66 * 100,000)) * 63% * 100%

= 89.0 therms

Mid-Life adjustment

In order to account for the likely replacement of existing heating and cooling equipment during the lifetime of this

[1601] Ideally, the System Efficiency should be obtained either by recording the AFUE of the unit, or performing a steady state efficiency test. The Distribution Efficiency can be estimated via a visual inspection and by referring to a look up table such as that provided by the Building Performance Institute: (see 'BPI Distribution Efficiency Table') or by performing duct blaster testing.

[1602] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1603] Based on average Nicor PY4 nameplate efficiencies derated by 15% for distribution losses.

[1604] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1605] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

measure, a mid-life adjustment should be applied. To calculate the adjustment, re-calculate the savings above using the following new baseline system efficiency assumptions:

Efficiency Assumption	System Type	New Baseline Efficiency
ηCool	Central AC (13.4 SEER2 * 0.85)	11.4 SEER2
	Heat Pump (14.3 SEER2 * 0.85)	12.2 SEER2
ηHeat	Electric Resistance (Baseboard or Electric Furnace)	1.0 COP
	Heat Pump (7.5HSPF/3.412)*0.85	1.87 COP
	Gas Furnace 80% AFUE * 0.85	68% AFUE
	Oil Furnace 83% AFUE * 0.85	71% AFUE
	Gas Boiler	84% AFUE
	Oil Boiler	86% AFUE

This reduced annual savings should be applied following the assumed remaining useful life of the existing equipment, estimate to be 10 years or 13 years for boilers.[1606] Note if the existing equipment efficiency is greater than the new baseline efficiency listed above, do not apply a mid-life adjustment.

MEASURE CODE: RS-SHL-WINS-V15-260101

REVIEW DEADLINE: 1/1/2030

[1606] This is intentionally longer than the assumption found in the early replacement measures as the application of this measure will occur in a variety of homes and will not be targeting those homes appropriate for early replacement HVAC systems.

5.6.5 Ceiling/Attic Insulation

DESCRIPTION

Insulation is added to the attic. This measure requires a member of the implementation staff evaluating the pre and post R-values and measure surface areas. The efficiency of the heating and cooling equipment in the home should also be evaluated if possible.

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure requires a member of the implementation staff or a participating contractor to evaluate the pre and post R-values and measure surface areas. The requirements for participation in the program will be defined by the utilities.

DEFINITION OF BASELINE EQUIPMENT

The existing condition will be evaluated by implementation staff or a participating contractor and is likely to be little or no attic insulation.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 30 years.[1607]

Note a mid-life adjustment to account for replacement of HVAC equipment during the measure life should be applied after 10 years or 13 years for boilers.[1608] See section below for detail.

DEEMED MEASURE COST

The actual installed cost for this measure should be used in screening.

LOADSHAPE

Loadshape R08 - Residential Cooling

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1609]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single family homes (during system peak hour)

[1607] As recommended in Guidehouse 'EMV Group A, Deliverable 16 EUL Research – Residential Insulation', prepared for California Public Utilities Commission, June 2021.

[1608] This is intentionally longer than the assumptions found in the early replacement measures as the application of this measure will occur in a variety of homes that will not be targeted for early replacement HVAC systems.

[1609] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

= 72%[1610]

$CF_{SSP, MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multifamily homes (during system peak hour)

= 67%[1611]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1612]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single family homes (average during PJM peak period)

= 46.6%[1613]

$CF_{PJM, MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multifamily homes (average during peak period)

= 28.5%

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Where available savings from shell insulation measures should be determined through a custom analysis. When that is not feasible for the program the following engineering algorithms can be used with the inclusion of an adjustment factor to de-rate the heating savings.

ΔkWh = (ΔkWh_cooling + ΔkWh_heatingElectric + ΔkWh_heatingFurnace)

Where:

ΔkWh_cooling = If central cooling, reduction in annual cooling requirement due to ceiling/attic insulation

= ((((1/R_old - 1/R_attic) * A_attic * (1-Framing_factor_attic)) * 24 * CDD * DUA * LoadFactor) / (1000 * ηCool)) * $ADJ_{AtticCool}$ * $IE_{NetCorrection}$ * %Cool

R_attic = R-value of new attic assembly (including all layers between inside air and outside air).

R_old = R-value value of existing assembly and any existing insulation.

(Minimum of R-3 for uninsulated assemblies)[1614]

A_attic = Total area of insulated ceiling/attic (ft^2)

Framing_factor_attic = Adjustment to account for area of framing

= 7%[1615]

[1610] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[1611] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

[1612] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1613] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1614] Component estimate of airfilm above and below, sheathing and sheet rock, (0.68+0.5+0.45+0.68 = 2.3) is rounded up to R-3.

[1615] Ibid.

24 = Converts hours to days

CDD = Cooling Degree Days

= dependent on location:[1616]

Climate Zone (City based upon)	CDD 65
1 (Rockford)	877
2 (Chicago)	1047
3 (Springfield)	1183
4 (Belleville)	1641
5 (Marion)	1450
Weighted Average[1617]	1098

DUA = Discretionary Use Adjustment (reflects the fact that people do not always operate their AC when conditions may call for it).

= 0.90 [1618]

LoadFactor = Factor to reflect expected relative load (and therefore savings) or homes with Room AC v Central AC.

= 1.0 for homes with central AC, 0.41 for homes with Room AC[1619]

1000 = Converts Btu to kBtu

ηCool = Efficiency (SEER2 or CEER) of cooling system (kBtu/kWh) * Distribution Efficiency

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for central cooling with ducts if only equipment efficiency is available). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1620] or if unknown assume the following.[1621] If unknown value is used, it should not

[1616] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 65°F. There is a county mapping table Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.
[1617] Weighted based on number of occupied residential housing units in each zone (US Census 2010).
[1618] This factor utilizes data from a metering study: Pigg, Scott, D. Caultlet, and K. Koski, (2016): "Improving Installation and Maintenace Practices for Minnesota Residentail Furnaces, Air Conditioners and Heat Pumps", prepared for Minnestora Department of Commerce, Division of Energy. COMM-201305222-72623. To correct for the different climatological conditions in Minnesota and Illinois, the analysis includes 19 homes that have actual annual operating hours above 453 hrs/yr (over 1/2 of the actual annual operating hours for the highest operating hours home in the study-905 hrs/yr). Additionally, the factor is adjusted from 0.87 to 0.90 to account for Illinois' hotter climate and higher number of muggy days. See DUA_Workbook_051525.xlsx for detailed data.
[1619] Based upon review of 102 room AC replacement projects completed in 2023 and 2024 for an Illinois multifamily energy efficiency program, the average room AC capacity installed was 11.41 MBh per living unit. From Section 5.3.3 for Central Air Conditioning, default central A/C capacity is 28 MBh. This results in a capacity scale factor of 11.41 / 28 = 0.41 when using room air conditioner cooling.
[1620] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).
[1621] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

be derated by age.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3
Room AC[1622]		
Non-IQ	10.9	10.9
IQ	9.7	9.7
Unknown (for use in program evaluation only)[1623]		
Single Family Non-IQ		10.6
Single Family IQ		10.3
Multi Family Non-IQ		10.3
Multi Family IQ		9.9
Unknown		10.3

$ADJ_{AtticCool}$ = Adjustment for cooling savings to account for inaccuracies in engineering algorithms[1624]

= 114%

$IE_{NetCorrection}$ = 100% if not income eligible or attic insulation is installed without air sealing

= 110% if installing air sealing and attic insulation in income eligible projects with a deemed NTG value of 1.0 to offset net savings adjustment inherent when using $ADJ_{AtticCool}$ of 114%[1625]

%Cool = Percent of homes that have cooling

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				

[1622] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[1623] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1624] As demonstrated in air sealing and insulation research by Navigant, see Navigant (2018). C*omEd and Nicor Gas Air Sealing and Insulation Research Report.* Presented to Commonwealth Edison Company and Nicor Gas Company. Adjustment factor was derived from a consumption data regression analysis with an experimental design that does not require further net savings adjustment for non-income eligible populations. During update cycle for version v.12, applied the percent change of NCEI Annual Normals CDD65 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all cooling-related adjustment values.

[1625] The additional value of 10% was selected to acknowledge that some portion of the regression-derived adjustment factors accounts for gross impact effects, and that removing net effects embedded in the adjustment factors would increase savings to some degree. A review of historical NTG values for air sealing and insulation measures in non-income eligible populations did not provide definitive guidance for estimating the net component of the adjustment factors. Historically, free ridership has ranged from 9% to 26% for like measures, and spillover has ranged from 1% to 14%, while NTGs have ranged from 0.75 to 1.05. The midpoint of the NTG range would be 0.90, a 10% reduction from 1.0.

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Unknown (for use in program evaluation only)[1626]	98.9%	96.5%	99.8%	98.7%	98.6%

kWh_heatingElectric = If electric heat (resistance baseboard, electric furnace or heat pump), reduction in annual electric heating due to attic insulation

= ((((1/R_old - 1/R_attic) * A_attic * (1-Framing_factor_attic)) * 24 * HDD) / (ηHeat * 3,412)) * $ADJ_{AtticElectricHeat}$*%ElectricHeat

HDD = Heating Degree Days

= Dependent on location:[1627]

Climate Zone (City based upon)	HDD 60
1 (Rockford)	5230
2 (Chicago)	4798
3 (Springfield)	4266
4 (Belleville)	3188
5 (Marion)	3390
Weighted Average[1628]	4631

ηHeat = Efficiency of heating system

= Actual Heating Efficiency * Distribution Efficiency (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1629] or if not available refer to default table below.[1630] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85% for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) (HSPF2/3.412)*0.85
	Before 2006	5.8	1.44

[1626] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.
[1627] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 60°F, consistent with the findings of Belzer and Cort, Pacific Northwest National Laboratory in "Statistical Analysis of Historical State-Level Residential Energy Consumption Trends," 2004. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.
[1628] Weighted based on number of occupied residential housing units in each zone.
[1629] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).
[1630] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) (HSPF2/3.412)*0.85
Heat Pump (if age unknown, assume 2006-2014)	After 2006 -2014	6.5	1.62
	2015 on	7	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1
Unknown (for use in program evaluation only)	N/A	N/A	1.32

3412 = Converts Btu to kWh

$ADJ_{AtticElectricHeat}$ = Adjustment for electric heating savings to account for inaccuracies in engineering algorithms[1631]

= 63%

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= 0 % for Fossil Fuel heat

= If unknown[1632], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[1633]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

[1631] As demonstrated in air sealing and insulation research by Navigant, Navigant (2018). C*omEd and Nicor Gas Air Sealing and Insulation Research Report.* Presented to Commonwealth Edison Company and Nicor Gas Company. During update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all heating-related adjustment values.

[1632] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1633] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

For example, energy savings from ceiling/attic insulation. Energy savings for air sealing are included in a separate example in Section 5.6.1: Air Sealing.

Assume a non-income eligible single family home in Chicago installs 700 ft^2 of attic insulation, completes air sealing, has 10.5 SEER Central AC and 2.26 (1.92 including distribution losses) COP Heat Pump, and has pre and post attic insulation R-values of R-5 and R-38, respectively:

ΔkWh = (ΔkWh_cooling + ΔkWh_heating)

= (((((1/5 - 1/38) * 700 * (1-0.07)) * 1,047 * 0.90 * 24)/ (1,000 * 10.5)) * 114% * 100% * 100%) + (((((1/5 - 1/38) * 700 * (1-0.07)) * 4,798 * 24) / (1.92 * 3,412)) * 63% * 100%)

= 277 + 1,252

= 1,529 kWh

ΔkWh_heatingFurnace = If *furnace* (fossil fueled or electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = ΔTherms * F_e * 29.3 * $ADJ_{AtticHeatFan}$

If electric furnace: = ΔkWh_heatingElectric * F_e * $ADJ_{AtticHeatFan}$

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[1634]

29.3 = kWh per therm

$ADJ_{AtticHeatFan}$ = Adjustment for fan savings to account for inaccuracies in engineering algorithms[1635]

= 113%

For example: energy savings from ceiling/attic insulation. Energy savings for air sealing are included in a separate example in Section 5.6.1: Air Sealing.

Assume a non-income eligible single family home in Chicago installs 700 ft^2 of attic insulation, completes air sealing, has a gas furnace with system efficiency of 66% (for therm calculation see Fossil Fuel Savings section), and has pre and post attic insulation R-values of R-5 and R-38, respectively:

ΔkWh = 150 * 0.0314 * 29.3 * 113%

= 156 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = (ΔkWh_cooling / FLH_cooling) * CF

Where:

FLH_cooling = Full load hours of air conditioning

[1634] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[1635] As demonstrated in air sealing and insulation research by Navigant, see Navigant (2018). C*omEd and Nicor Gas Air Sealing and Insulation Research Report.* Presented to Commonwealth Edison Company and Nicor Gas Company. Adjustment factor was derived from a consumption data regression analysis with an experimental design that does not require further net savings adjustment for non-income eligible populations. During update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all heating-related adjustment values.

= Dependent on location as below:[1636]

Climate Zone (City based upon)	Single Family	Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1082	982
5 (Marion)	956	868
Weighted Average[1637]		
ComEd	676	603
Ameren	875	791
Statewide	731	655

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1638]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single family homes (during system peak hour)

= 72%[1639]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multifamily homes (during system peak hour)

= 67%[1640]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1641]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single family homes (average during PJM peak period)

= 46.6%[1642]

[1636] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[1637] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[1638] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[1639] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[1640] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

[1641] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1642] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

$CF_{PJM, MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multifamily homes (average during peak period)

= 28.5%

For example, energy savings from ceiling/attic insulation. Energy savings for air sealing are included in a separate example in Section 5.6.1: Air Sealing.

Assume a non-income eligible single family home in Chicago installs 700 ft^2 of attic insulation, has 10.5 SEER Central AC and 2.26 COP Heat Pump, and has pre and post attic insulation R-values of R-5 and R-38, respectively:

ΔkW_{SSP} = 277 / 709 * 0.68

= 0.26 kW

ΔkW_{PJM} = 156 / 709 * 0.466

= 0.10 kW

FOSSIL FUEL SAVINGS

If Fossil Fuel heating:

$$\Delta Therms = ((((1/R_old - 1/R_attic) * A_attic * (1-Framing_factor_attic)) * 24 * HDD) / (\eta Heat * 100{,}000\ Btu/therm) * ADJ_{AtticGasHeat} * IE_{NetCorrection} * \%FossilHeat$$

Where:

HDD = Heating Degree Days

= Dependent on location:[1643]

Climate Zone (City based upon)	HDD 60
1 (Rockford)	5230
2 (Chicago)	4798
3 (Springfield)	4266
4 (Belleville)	3188
5 (Marion)	3390
Weighted Average[1644]	4631

ηHeat = Efficiency of heating system

= Equipment efficiency * distribution efficiency

= Actual (where it is possible to measure or reasonably estimate).[1645] Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1646] or if not available,

[1643] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 60°F, consistent with the findings of Belzer and Cort, Pacific Northwest National Laboratory in "Statistical Analysis of Historical State-Level Residential Energy Consumption Trends," 2004. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[1644] Weighted based on number of occupied residential housing units in each zone (US Census 2010).

[1645] Ideally, the System Efficiency should be obtained either by recording the AFUE of the unit, or performing a steady state efficiency test. The Distribution Efficiency can be estimated via a visual inspection and by referring to a look up table such as that provided by the Building Performance Institute: (see 'BPI Distribution Efficiency Table') or by performing duct blaster testing.

[1646] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

use 72% for existing system efficiency.[1647] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85%.

$ADJ_{AtticGasHeat}$ = Adjustment for gas heating savings to account for inaccuracies in engineering algorithms[1648]

= 76%

$IE_{NetCorrection}$ = 100% if not income eligible or attic insulation is installed without air sealing

= 110% if installing air sealing and attic insulation in income eligible projects with a deemed NTG value of 1.0 to offset net savings adjustment inherent when using $ADJ_{AtticGasHeat}$ of 76% [1649]

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for Fossil fuel heat

= 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= If unknown[1650], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[1651]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Other factors as defined above.

[1647] Based on average Nicor PY4 nameplate efficiencies derated by 15% for distribution losses.

[1648] As demonstrated in air sealing and insulation research by Navigant, Navigant (2018). C*omEd and Nicor Gas Air Sealing and Insulation Research Report.* Presented to Commonwealth Edison Company and Nicor Gas Company. Adjustment factor was derived from a consumption data regression analysis with an experimental design that does not require further net savings adjustment for non-income eligible populations. During update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all heating-related adjustment values.

[1649] The additional value of 10% was selected to acknowledge that some portion of the regression-derived adjustment factors accounts for gross impact effects, and that removing net effects embedded in the adjustment factors would increase savings to some degree. A review of historical NTG values for air sealing and insulation measures in non-income eligible populations did not provide definitive guidance for estimating the net component of the adjustment factors. Historically, free ridership has ranged from 9% to 26% for like measures, and spillover has ranged from 1% to 14%, while NTGs have ranged from 0.75 to 1.05. The midpoint of the NTG range would be 0.90, a 10% reduction from 1.0.

[1650] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1651] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

For example, energy savings from ceiling/attic insulation. Energy savings for air sealing are included in a separate example in Section 5.6.1: Air Sealing.

Assume a non-income eligible single family home in Chicago installs 700 ft^2 of attic insulation, has a gas furnace with system efficiency of 66%, and has pre and post attic insulation R-values of R-5 and R-38, respectively:

ΔTherms = ((((1/5 - 1/38) * 700 * (1-0.07)) * 24 * 4,798) / (0.66 * 100,000)) * 76% * 100% * 100%

= 150 therms

Mid-Life adjustment

In order to account for the likely replacement of existing heating and cooling equipment during the lifetime of this measure, a mid-life adjustment should be applied. To calculate the adjustment, re-calculate the savings above using the following new baseline system efficiency assumptions:

Efficiency Assumption	System Type	New Baseline Efficiency
ηCool	Central AC (13.4 SEER2 * 0.85)	11.4 SEER2
	Heat Pump (14.3 SEER2 * 0.85)	12.2 SEER2
ηHeat	Electric Resistance (Baseboard or Electric Furnace)	1.0 COP
	Heat Pump (7.5HSPF/3.412)*0.85	1.87 COP
	Gas Furnace 80% AFUE * 0.85	68% AFUE
	Oil Furnace 83% AFUE * 0.85	71% AFUE
	Gas Boiler	84% AFUE
	Oil Boiler	86% AFUE

This reduced annual savings should be applied following the assumed remaining useful life of the existing equipment, estimate to be 10 years or 13 years for boilers.[1652] Note if the existing equipment efficiency is greater than the new baseline efficiency listed above, do not apply a mid-life adjustment.

MEASURE CODE: RS-SHL-AINS-V09-260101

REVIEW DEADLINE: 1/1/2030

[1652] This is intentionally longer than the assumption found in the early replacement measures as the application of this measure will occur in a variety of homes and will not be targeting those homes appropriate for early replacement HVAC systems.

5.6.6 Rim/Band Joist Insulation

DESCRIPTION

This measure describes savings from adding insulation (either rigid or spray foam) to rim/band joist cavities. This measure requires a member of the implementation staff evaluating the pre- and post-project R-values and to measure surface areas. The efficiency of the heating and cooling equipment in the home should also be evaluated if possible.

A conditioned space is defined as a space within the thermal envelope[1653] of the building that is intentionally heated or cooled for occupancy (bedrooms, living room, bathrooms, kitchen, etc.). A non-conditioned space is defined as a space outside of the thermal envelope of the building that is not intentionally heated or cooled for occupancy (roof attic, etc.). A semi-conditioned space is defined as a space within the thermal envelope that is not intentionally heated or cooled for occupancy (unfinished basement).

This measure was developed to be applicable to the following program types: RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

This measure requires a member of the implementation staff or a participating contractor to evaluate the pre and post R-values and measure surface areas. The requirements for participation in the program will be defined by the utilities.

DEFINITION OF BASELINE EQUIPMENT

The existing condition will be evaluated by implementation staff or a participating contractor and is likely to be empty wall cavities and little or no attic insulation.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 30 years.[1654]

Note a mid-life adjustment to account for replacement of HVAC equipment during the measure life should be applied after 10 years or 13 years for boilers[1655]. See section below for detail.

DEEMED MEASURE COST

The actual installed cost for this measure should be used in screening.

LOADSHAPE

Loadshape R08 - Residential Cooling

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's capacity market.

[1653]Thermal envelope refers to the shell of the building as a barrier to unwanted heat or mass transfer between the interior of the building and the outside conditions: IPCC, https://archive.ipcc.ch/publications_and_data/ar4/wg3/en/ch6s6-4-2.html

[1654] As recommended in Guidehouse 'EMV Group A, Deliverable 16 EUL Research – Residential Insulation', prepared for California Public Utilities Commission, June 2021.

[1655] This is intentionally longer than the assumptions found in the early replacement measures as the application of this measure will occur in a variety of homes that will not be targeted for early replacement HVAC systems.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1656]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single family homes (during system peak hour)

= 72%[1657]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multifamily homes (during system peak hour)

= 67%[1658]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1659]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single family homes (average during PJM peak period)

= 46.6%[1660]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multifamily homes (average during peak period)

= 28.5%

Algorithm

CALCULATION OF SAVINGS

ELECTRIC ENERGY SAVINGS

Where available savings from shell insulation measures should be determined through a custom analysis. When that is not feasible for the program the following engineering algorithms can be used with the inclusion of an adjustment factor to de-rate the heating savings.

ΔkWh = (ΔkWh_cooling + ΔkWh_ heatingElectric + ΔkWh_heatingFurnace)

Where:

ΔkWh_cooling = If central cooling, reduction in annual cooling requirement due to insulation

$$= \frac{\left(\frac{1}{R_{Old}} - \frac{1}{R_{Rim}}\right) * A_{Rim} * (1 - FramingFactor_{Rim}) * CDD * 24 * DUA * LoadFactor * ADJ_{BasementCool} * \%Cool}{(1000 * \eta Cool)}$$

R_{Rim} = R-value of new rim/band joist assembly (including all layers between inside air and outside air).

[1656] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[1657] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[1658] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015
[1659] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1660] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

R_{old} = R-value value of existing assembly and any existing insulation.

(Minimum of R-5 for uninsulated assemblies)[1661]

A_{Rim} = Net area of insulated rim/band joist (ft^2)

$FramingFactor_{Rim}$ = Adjustment to account for area of framing

= 5%[1662]

24 = Converts hours to days

CDD = Cooling Degree Days

= dependent on location, if unknown assume semi-conditioned:[1663]

Climate Zone (City based upon)	Conditioned (CDD 65)	Semi-conditioned (CDD 75)[1664]
1 (Rockford)	877	326
2 (Chicago)	1047	354
3 (Springfield)	1183	448
4 (Belleville)	1641	532
5 (Marion)	1450	516
Weighted Average[1665]	1098	380

DUA = Discretionary Use Adjustment (reflects the fact that people do not always operate their AC when conditions may call for it).

= 0.90 [1666]

LoadFactor = Factor to reflect expected relative load (and therefore savings) or homes with Room AC v Central AC.

= 1.0 for homes with central AC, 0.41 for homes with Room AC[1667]

[1661] An estimate based on review of Madison Gas and Electric, Exterior Wall Insulation, R-value for no insulation in walls, and NREL's Building Energy Simulation Test for Existing Homes (BESTEST-EX).

[1662] Assumes the average framing factor for joists running from front-to-back (0.094) and from side-to-side (0). The front-to-back FF was calculated based on 1.5" joists for every 16" (1.5"/16" = 0.094). The side-to-side FF is 0 since joists are continuous and uninterrupted.

[1663]National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 65°F. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[1664] Five year-average (2018 to 2022) cooling degree days with a base temperature of 75 F. Data from DegreeDays.net were used in this table because the climate normals from NCEI/NCDC used elsewhere are not available at base temps above 72F.

[1665] Weighted based on number of occupied residential housing units in each zone (US Census 2010).

[1666]This factor utilizes data from a metering study: Pigg, Scott, D. Caultlet, and K. Koski, (2016): "Improving Installation and Maintenace Practices for Minnesota Residentail Furnaces, Air Conditioners and Heat Pumps", prepared for Minnestora Department of Commerce, Division of Energy. COMM-201305222-72623. To correct for the different climatological conditions in Minnesota and Illinois, the analysis includes 19 homes that have actual annual operating hours above 453 hrs/yr (over 1/2 of the actual annual operating hours for the highest operating hours home in the study-905 hrs/yr). Additionally, the factor is adjusted from 0.87 to 0.90 to account for Illinois' hotter climate and higher number of muggy days. See DUA_Workbook_051525.xlsx for detailed data.

[1667] Based upon review of 102 room AC replacement projects completed in 2023 and 2024 for an Illinois multifamily energy efficiency program, the average room AC capacity installed was 11.41 MBh per living unit. From Section 5.3.3 for Central Air Conditioning, default central A/C capacity is 28 MBh. This results in a capacity scale factor of 11.41 / 28 = 0.41 when using room air conditioner cooling.

1000 = Converts Btu to kBtu

ηCool = Efficiency (SEER2 or CEER) of cooling system (kBtu/kWh) * Distribution Efficiency

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for central cooling with ducts if only equipment efficiency is available). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1668] or if unknown assume the following.[1669] If unknown value is used, it should not be derated by age.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3
Room AC[1670]		
Non-IQ	10.9	10.9
IQ	9.7	9.7
Unknown (for use in program evaluation only)[1671]		
Single Family Non-IQ		10.6
Single Family IQ		10.3
Multi Family Non-IQ		10.3
Multi Family IQ		9.9
Unknown		10.3

$ADJ_{BasementCool}$ = Adjustment for cooling savings from basement wall and rim/band joist insulation to account for prescriptive engineering algorithms overclaiming savings[1672]

= 75%

%Cool = Percent of homes that have cooling

[1668] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1669] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

[1670] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[1671] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1672] As demonstrated in two years of metering evaluation by Opinion Dynamics, see Memo "Results for AIC PY6 HPwES Billing Analysis", dated February 20, 2015. TAC negotiated adjustment factor is 80%. During update cycle for version v.12, applied the percent change of NCEI Annual Normals CDD65 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all cooling-related adjustment values.

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[1673]	98.9%	96.5%	99.8%	98.7%	98.6%

kWh_heatingElectric = If electric heat (resistance baseboard, electric furnace or heat pump), reduction in annual electric heating due to insulation

$$= \frac{\left(\frac{1}{R_{old}} - \frac{1}{R_{Rim}}\right) * A_{Rim} * (1 - FramingFactor_{Rim}) * HDD * 24 * ADJ_{BasementHeat} * \%ElectricHeat}{(\eta Heat * 3412)}$$

HDD = Heating Degree Days

= Dependent on location, if unknown assume semi-conditioned:[1674]

Climate Zone (City based upon)	Conditioned (HDD 60)	Semi-conditioned (HDD 50)
1 (Rockford)	5230	3233
2 (Chicago)	4798	2845
3 (Springfield)	4266	2456
4 (Belleville)	3188	1651
5 (Marion/Murphysboro)	3390	1750
Weighted Average[1675]	4631	2732

ηHeat = Efficiency of heating system

= Actual Heat Efficiency * Distribution Efficiency (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1676] or if not available, refer to default table below.[1677] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85% for heat pumps.

[1673] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.
[1674] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 60°F for a conditioned basement and 50°F for an unconditioned basement), consistent with the findings of Belzer and Cort, Pacific Northwest National Laboratory in "Statistical Analysis of Historical State-Level Residential Energy Consumption Trends," 2004. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.
[1675] Weighted based on number of occupied residential housing units in each zone.
[1676] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).
[1677] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency)= (HSPF2/3.412)*0.85
Heat Pump (if age unknown, assume 2006-2014)	Before 2006	5.8	1.44
	2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown (for use in program evaluation only)[1678]	N/A	N/A	1.32

3412 = Converts Btu to kWh

$ADJ_{BasementHeat}$ = Adjustment for basement wall and rim/band joist insulation to account for prescriptive engineering algorithms overclaiming savings[1679]

= 63%

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= 0 % for Fossil Fuel heat

= If unknown[1680], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[1681]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is

[1678] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1678] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps.

[1679] TAC negotiated adjustment factor was 60%, then during update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all heating-related adjustment values.

[1680] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1681] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

known that the participant has a gas supply, the values from the gas utility above should be applied.

For example, a single-family home in Chicago with 100 ft^2 of uninsulated rim joist cavities in an semi-conditioned basement that is insulated to R-13. The home has 10.5 SEER Central AC and 2.26 (1.92 including distribution losses) COP Heat Pump:

ΔkWh = (ΔkWh_cooling + ΔkWh_heating)

= (((1/5 - 1/13) * 100 * (1-0.05) * 354 * 24 * 0.90 * 1 * 0.75) / (1000 * 10.5)) + (((1/5 - 1/13) * 100 * (1-0.05) * 2845 * 24 * 0.63 * 1) / (1.92 * 3412))

= 6.4 + 76.8

= 83.25 kWh

ΔkWh_heatingFurnace = If *furnace* (fossil fueled or electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = ΔTherms * F_e * 29.3

If electric furnace: = ΔkWh_heatingElectric * F_e

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[1682]

29.3 = kWh per therm

For example, a single family home in Chicago with 100 ft^2 of uninsulated rim joist cavities in an unconditioned basement that is insulated to R-13. The home has a gas furnace with system efficiency of 66% (for therm calculation see Fossil Fuel Savings section):

ΔkWh = 7.62 * 0.0314 * 29.3

= 7.0 kWh

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = (ΔkWh_cooling / FLH_cooling) * CF

Where:

FLH_cooling = Full load hours of air conditioning

= Dependent on location as below:[1683]

[1682] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[1683] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

Climate Zone (City based upon)	Single Family	Multifamily		
	Conditioned	Semi-Conditioned[1684]	Conditioned	Semi-Conditioned
1 (Rockford)	547	203	499	185
2 (Chicago)	709	240	629	213
3 (Springfield)	779	295	707	268
4 (Belleville)	1082	351	982	318
5 (Marion)	956	340	868	309
Weighted Average[1685]				
ComEd	676	234	603	209
Ameren	875	303	791	274
Statewide	731	253	655	227

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1686]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single family homes (during system peak hour)

= 72%[1687]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multifamily homes (during system peak hour)

= 67%[1688]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1689]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single family homes (average during PJM peak period)

= 46.6%[1690]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multifamily homes (average during peak period)

= 28.5%

[1684] Semi-Conditioned are estimated based on the ratio of CDD between conditioned and semi-conditioned spaces.
[1685] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.
[1686] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[1687] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[1688] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015
[1689] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1690] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

For example, a single family home in Chicago with 100 ft^2 of semi-insulated rim joist cavities in an unconditioned basement that is insulated to R-13. The home has 10.5 SEER Central AC and 2.26 (1.92 including distribution losses) COP Heat Pump:

ΔkW_{SSP} = 6.4 / 240 * 0.68
= 0.018 kW

ΔkW_{PJM} = 6.4 / 240 * 0.466
= 0.012 kW

FOSSIL FUEL SAVINGS

If Fossil Fuel heating:

$$\Delta Therms = \frac{\left(\frac{1}{R_{old}} - \frac{1}{R_{Rim}}\right) * A_{Rim} * (1 - FramingFactor_{Rim}) * HDD * 24 * ADJ_{BasementHeat} * \%FossilHeat}{(\eta Heat * 100{,}000)}$$

Where:

ηHeat = Efficiency of heating system

= Equipment efficiency * distribution efficiency

= Actual (where it is possible to measure or reasonably estimate).[1691] Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1692] or if not available, use 72% for existing system efficiency.[1693] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available use 85% for central ducted systems.

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for Fossil Fuel heat

= 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= If unknown[1694], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%

[1691] Ideally, the System Efficiency should be obtained either by recording the AFUE of the unit, or performing a steady state efficiency test. The Distribution Efficiency can be estimated via a visual inspection and by referring to a look up table such as that provided by the Building Performance Institute: (see 'BPI Distribution Efficiency Table') or by performing duct blaster testing.
[1692] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).
[1693] Based on average Nicor PY4 nameplate efficiencies derated by 15% for distribution losses.
[1694] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
All DUs[1695]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Other factors as defined above.

For example, a single family home in Chicago with 100 ft^2 of uninsulated rim joist cavities in an unconditioned basement that is insulated to R-13. The home has a gas furnace with system efficiency of 66%:

ΔTherms = ((1/5 - 1/13) * 100 * (1-0.05) * 2845 * 24 * 0.63 * 1) / (0.66 * 100,000)
= 7.62 therms

Mid-Life adjustment

In order to account for the likely replacement of existing heating and cooling equipment during the lifetime of this measure, a mid-life adjustment should be applied. To calculate the adjustment, re-calculate the savings above using the following new baseline system efficiency assumptions:

Efficiency Assumption	System Type	New Baseline Efficiency
ηCool	Central AC (13.4 SEER2 * 0.85)	11.4 SEER2
	Heat Pump (14.3 SEER2 * 0.85)	12.2 SEER2
ηHeat	Electric Resistance (Baseboard or Electric Furnace)	1.0 COP
	Heat Pump (7.5HSPF/3.412)*0.85	1.87 COP
	Gas Furnace 80% AFUE * 0.85	68% AFUE
	Oil Furnace 83% AFUE * 0.85	71% AFUE
	Gas Boiler	84% AFUE
	Oil Boiler	86% AFUE

This reduced annual savings should be applied following the assumed remaining useful life of the existing equipment, estimate to be 10 years or 13 years for boilers.[1696] Note if the existing equipment efficiency is greater than the new baseline efficiency listed above, do not apply a mid-life adjustment.

[1695] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

[1696] This is intentionally longer than the assumption found in the early replacement measures as the application of this measure will occur in a variety of homes and will not be targeting those homes appropriate for early replacement HVAC systems.

5.6.7 Low-E Storm Window

DESCRIPTION

Emissivity is a measure of thermal radiation emitted by an object's surface. Emissivity values range from 0 to 1 with 1 being the emissivity of a black body. Low emissivity (low-e) storm window inserts reduce the rate of thermal radiation of the window assembly through the interaction of multiple properties. The low-e surface of the insert means that the window will transfer heat at a reduced rate. The newly created air gap between the window and the insert combined with the low emissivity of the insert improves thermal performance of the window assembly. The inserts include weather-stripping as a means of sealing the connection which reduces air infiltration. This measure offers benefits during both heating and cooling seasons, for both natural gas and electricity. In addition to energy benefits, this measure offers non-energy benefits including increased comfort and noise reduction.

The calculation of savings presented in this section apply to single and multifamily residential applications with no portable window air conditioners. Small commercial applications with operating characteristics similar to a residential profile are also eligible for the savings presented here.

This measure was developed to be applicable to the following program types: RF, DI. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is a window insert installed over either the interior or exterior of the baseline window. The insert must be ENERGY STAR[1697] certified and meet the ENERGY STAR storm windows key product criteria.

ENERGY STAR key product criteria for storm windows[1698]

Climate Zone	Emissivity	Solar Transmission
1 - Rockford	≤ 0.22	> 0.55
2 - Chicago		
3 - Springfield		
4 - Belleville		Any
5 – Marion		

DEFINITION OF BASELINE EQUIPMENT

The baseline condition is an existing single-pane or double-pane window with clear glass and any frame type: metal, vinyl, or wood.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 20 years.[1699]

DEEMED MEASURE COST

The incremental cost for this measure is $7.85 per square foot material cost. Applications using professional window installers should include an additional $30 per window installation cost.[1700]

LOADSHAPE

Loadshape R08 - Residential Cooling
Loadshape R09 - Residential Electric Space Heat

[1697] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.
[1698] ENERGY STAR Storm Windows Key Product Criteria, accessed February 2020.
[1699] Pacific Northwest National Laboratory for the U.S. Department of Energy, "Task ET-WIN-PNNL-FY13-01-5.3: Database of Low-e Storm Window Energy Performance across U.S. Climate Zones," September 2013: page 5.
[1700] Ibid.

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the average savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[1701]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

= 72%[1702]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[1703]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[1704]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1705]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta\text{kWh} = \Delta\text{kWh}_{\text{cooling}} + \Delta\text{kWh}_{\text{heatingElectric}} + \Delta\text{kWh}_{\text{heatingFurnace}}$$

$$\Delta\text{kWh}_{\text{cooling}} = \text{CS}_{\text{cz}} * \text{Area}_{\text{window}}$$

$$\Delta\text{kWh}_{\text{heatingElectric}} = \text{EHS}_{\text{cz}} * \text{Area}_{\text{window}}$$

$$\Delta\text{kWh}_{\text{heatingFurnace}} = \Delta\text{Therms} * \text{F}_{\text{e}} * 29.3$$

[1701] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[1702] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[1703] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015
[1704] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1705] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Where:

CS_{cz} = Annual cooling savings per area of window by climate zone, see table below.

Cooling savings per window area by climate zone and baseline window condition[1706]

Climate Zone	Single Pane Base Window (kWh/ft^2)	Double Pane Base Window (kWh/ft^2)
1 - Rockford	0.46	0.33
2 - Chicago	0.47	0.34
3 - Springfield	0.62	0.45
4 - Belleville	0.88	0.64
5 - Marion	0.77	0.56

EHS_{cz} = Annual electric heating savings per area of window by climate zone, see table below

Heating savings per window area by climate zone, heating type, and baseline window condition[1707]

	Electric Resistance Heat (Baseboard or Electric Furnace)		Electric Heat Pump	
Climate Zone	Single Pane Base Window (kWh/ft^2)	Double Pane Base Window (kWh/ft^2)	Single Pane Base Window (kWh/ft^2)	Double Pane Base Window (kWh/ft^2)
1 - Rockford	16.84	1.90	9.31	1.05
2 - Chicago	16.09	1.81	8.89	1.00
3 - Springfield	13.78	1.55	7.61	0.86
4 - Belleville	10.63	1.20	5.87	0.66
5 - Marion	10.82	1.22	5.98	0.67

$Area_{window}$ = Total area of installed window inserts. Use site specific value.

$\Delta Therms$ = Therm savings from fossil fuel heating as calculated below

F_e = Furnace Fan energy consumption as a percentage of annual fuel consumption,

[1706] Based on savings modeled by EPA, "ES Storm Windows RESFEN Data and Calculations.xlsx", April 2017. Whole House Cooling energy values from the "Raw Data-Exterior Storm Windows" and "Raw Data-Interior Storm Windows," Climate Zone 5, Location IL Chicago, wood frame, single pane, exterior low-E (0.148 panel) and interior low-E (0.148 panel) were used to calculated savings. EPA only reported single pane modeling results. In order to estimate impacts for double pane windows, ratios of double pane to single pane cooling energy was applied as reported by the Pacific Northwest National Laboratory for the U.S. Department of Energy, "Task ET-WIN-PNNL-FY13-01-5.3: Database of Low-e Storm Window Energy Performance across U.S. Climate Zones," September 2013. Values from Appendix C, table C.8 for Chicago, Illinois were used to calculate the ratio of double pane to single pane cooling energy. See "Low E Window Workpaper Supporting Calculations.xlsx" for reference. The was data modified for different heating zones of Illinois.

[1707] Based on savings modeled by EPA, "ES Storm Windows RESFEN Data and Calculations.xlsx", April 2017. Whole House Heating energy values from the "Raw Data-Exterior Storm Windows" and "Raw Data-Interior Storm Windows," Climate Zone 5, Location IL Chicago, wood frame, single pane, exterior low-E (0.148 panel) and interior low-E (0.148 panel) were used to calculated savings. EPA only reported single pane modeling results. In order to estimate impacts for double pane windows, ratios of double pane to single pane cooling energy was applied as reported by the Pacific Northwest National Laboratory for the U.S. Department of Energy, "Task ET-WIN-PNNL-FY13-01-5.3: Database of Low-e Storm Window Energy Performance across U.S. Climate Zones," September 2013. Values from Appendix C, table C.8 for Chicago, Illinois were used to calculate the ratio of double pane to single pane heating energy. See "Low E Window Workpaper Supporting Calculations.xlsx" for reference. To convert from "Furnace" savings to electric, it is assumed a furnace efficiency of 72%, electric resistance of 100% and heat pump of 1.81 (average of pre-2006 and 2006-2014 federal standard).

3.14%[1708]

29.3 = Conversion factor, kWh per therm

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta \mathrm{kW} = \left(\frac{\Delta \mathrm{kWh}_{\mathrm{cooling}}}{\mathrm{FLH}_{\mathrm{cooling}}}\right) * \mathrm{CF}$$

Where:

$FLH_{cooling}$ = Full load hours of air conditioning based on climate zone.

= Dependent on location:[1709]

Climate Zone (City based upon)	Single Family	Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1,082	982
5 (Marion)	956	868
Weighted Average[1710]		
ComEd	676	603
Ameren	875	791
Statewide	731	655

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[1711]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

= 72%[1712]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

[1708] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[1709] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[1710] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[1711] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[1712] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

= 67%[1713]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[1714]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1715]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

FOSSIL FUEL SAVINGS

$$\Delta Therms = GHS_{cz} * Area_{window}$$

Where:

GHS_{cz} = Annual fossil fuel heating savings per area of window by climate zone, see table below

Heating savings per window area by climate zone and baseline window condition [1716]

Climate Zone	Single Pane Base Window (therms/ft^2)	Double Pane Base Window (therms/ft^2)
1 - Rockford	0.80	0.09
2 - Chicago	0.76	0.09
3 - Springfield	0.65	0.07
4 - Belleville	0.50	0.06
5 - Marion	0.51	0.06

$Area_{window}$ = Total area of installed window inserts. Use site specific value.

[1713] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

[1714] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1715] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1716] Based on savings modeled by EPA, "ES Storm Windows RESFEN Data and Calculations.xlsx", April 2017. Whole House Heating energy values from the "Raw Data-Exterior Storm Windows" and "Raw Data-Interior Storm Windows," Climate Zone 5, Location IL Chicago, wood frame, single pane, exterior low-E (0.148 panel) and interior low-E (0.148 panel) were used to calculated savings. EPA only reported single pane modeling results. In order to estimate impacts for double pane windows, ratios of double pane to single pane cooling energy was applied as reported by the Pacific Northwest National Laboratory for the U.S. Department of Energy, "Task ET-WIN-PNNL-FY13-01-5.3: Database of Low-e Storm Window Energy Performance across U.S. Climate Zones," September 2013. Values from Appendix C, table C.8 for Chicago, Illinois were used to calculate the ratio of double pane to single pane heating energy. See "Low E Window Workpaper Supporting Calculations.xlsx" for reference.

For example, a single family gas heated residence in Rockford installs 10 window inserts over single pane windows. Each window is 12 square feet for a total window area of 120 square feet.

$$\Delta Therms = 0.80 * 120 = 95.81\ therms$$

$$\Delta kWh = 0.46 * 120 + 95.81 * 0.0314 * 29.3 = 143.37\ kWh$$

$$\Delta kW_{PJM} = \left(\frac{143.37}{547}\right) * 0.466 = 0.12\ kW$$

REVIEW DEADLINE: 1/1/2028

5.6.8 High Performance Windows

DESCRIPTION

High Performance Windows (HPWs) greatly improve building thermal envelope performance compared to code standard double-glazed windows. HPWs must achieve a U-value ≤ 0.22 for the Northern climate zone,[1717] or ≤ 0.25 for the North-Central climate zone. High performance windows significantly decrease heat loss through a building's envelope in a number of ways: by adding one or more additional panes of glass in the insulating glass unit (IGU), applying additional coatings to the glass panes, adding new gas fill, and/or using thermally improved spacers.

HPWs' reduced heat transfer significantly effects home energy savings as windows are often the weakest part of any building envelope. In addition to reducing heat transfer, HPWs also reduce air infiltration, thereby contributing to decreased HVAC loads. HPWs provide benefits for both heating and cooling seasons, and for both natural gas- and electrically-heated and cooled homes. They also have non-energy benefits such as increased thermal comfort and decreased outside noise.

This measure was developed for the following program types: New Construction (NC), Time of Sale (TOS), and Early Replacement (EREP). If applied to other program types, the measure savings should be verified.

By default, any "standard" window replacement (i.e. replacing an existing window of the same size with no structural changes to building) should be considered TOS/EREP for savings purposes unless the local code is explicitly triggered, in which case NC savings values shall be used.[1718]

DEFINITION OF EFFICIENT EQUIPMENT

HPWs are windows that meet the ENERGY STAR®[1719] version 7.0 performance specifications shown below:

Table 1: Key Product Criteria for High Performance Windows[1720]

IL Degree-Day Zone	ENERGY STAR Climate Zone	U-Value	SHGC	Prescriptive or Performance-Based
1 – Rockford 2 – Chicago 3 – Springfield	Northern	≤ 0.22	≥ 0.17	Prescriptive
		= 0.23	≥ 0.35	Equivalent Energy Performance
		= 0.24		
		= 0.25	≥ 0.40	
		= 0.26		
4 – Belleville	North-Central	≤ 0.25	≤ 0.40	Prescriptive
5 – Marion				Prescriptive

HPWs can achieve these performance specifications in a number of ways. Some examples of HPWs include:

- Thin Triple Windows (TTW) – the insulating glass unit (IGU) contains three panes of glass. A thin pane of center glass allows the IGU to fit within a standard window frame, eliminating the need to redesign the window. The inclusion of a thin pane of center glass allows for an additional surface for low-E coating, reducing the window's emissivity of thermal radiation and the rate of heat transfer by improving the U-value of the IGU and overall assembly. TTWs have two equal width panes of glass on the exterior and

[1717] In some cases, HPWs can have U-values of up to 0.26 in the Northern climate zone if the window meets alternative, performance-based SHGC thresholds. See **Error! Reference source not found.** for the specifications.

[1718] Preliminary analysis indicates an overwhelming majority of Illinois residents live in municipalities with code exemptions for windows being replaced for the same size/in the existing opening (e.g. Chicago does not require a building permit for "repairing or replacing (in-kind) an exterior window or skylight in the existing opening". Link: https://www.chicago.gov/city/en/sites/guide-to-building-permits/home/help/faq/DOB/bldg-permit-not-required/worktype/exterior.html). Therefore the assumption is that code is not triggered until proven otherwise. For future TRM revisions, this assumption may be revisited.

[1719] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

[1720] ENERGY STAR® Version 7.0 Residential Windows, Doors, and Skylights Final Specification.

interior of the IGU and a thin center piece of glass that allows the IGU to fit within an existing double-pane window frame.

- Triple Pane Windows – conventional triple pane windows that contain three panes of standard thickness glass. These windows provide an additional surface for a low-e coating and provide improved thermal performance by decreasing a window's emissivity and improving the window's resistance to heat loss. These windows are typically heavier than double-panes or TTWs and require a redesign of the window to allow the heavier, wider IGU to fit within the window frame.
- Double-pane windows that have low-e coatings on the two surfaces that face the cavity between the two panes of glass as well as on the interior-facing interior pane of glass, warm edge spacers, and improved frame thermal properties (e.g., adding foam or other insulation to the frame cavities).[1721]

DEFINITION OF BASELINE EQUIPMENT

New Construction: The tables below show International Energy Conservation Code (IECC) 2018 and IECC 2021 window codes for new construction. For first permits dated November 1, 2022 or later in the city of Chicago, or January 1, 2024 for the remainder of Illinois, residential new construction must be built in accordance with IECC 2021.

Table 2: IECC – Fenestration Requirements[1722,1723]

IL Degree-Day Zone	IECC Climate Zone	U-Value	SHGC
1 – Rockford	5	≤ 0.30	*Not Rated*[1724] (IECC 2018) ≤ 0.40 (IECC 2021)
2 – Chicago			
3 – Springfield			
4 – Belleville	4	≤ 0.32 (IECC 2018) ≤ 0.30 (IECC 2021)	*Not Rated*[1725] (IECC 2018) ≤ 0.40 (IECC 2021)
5 – Marion			

Time of Sale and Early Replacement in Existing Homes:

Table 3: Existing Homes – Existing Window Values: Double Pane[1726]

2 – Chicago		
3 – Springfield		
4 – Belleville		
5 – Marion		

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 40 years.[1728]

The remaining life of existing equipment is assumed to be 13 years.[1729]

DEEMED MEASURE COST

The incremental cost for this measure depends on the program delivery type/baseline and climate zone.

New Construction (NC) and Time of Sale (TOS): includes only equipment cost above baseline:

IL Degree-Day Zone	ENERGY STAR Climate Zone	NC or TOS[1730]
1 – Rockford 2 – Chicago 3 - Springfield	Northern	$3.85/ft^2
4 – Belleville 5 – Marion	North-Central	$2.18/ft^2

Early Replacement (EREP): Actual equipment and labor costs for installation, less the present value of the assumed deferred replacement cost, should be used. If this is unknown, assume the defaults below. The deferred cost (after 13 years) of replacing existing windows with a new code required double-pane baseline unit is assumed to be $48.50 per square foot[1731].

IL Degree-Day Zone	ENERGY STAR Climate Zone	EREP
1 – Rockford 2 – Chicago 3 - Springfield	Northern	$52.35/ft^2
4 – Belleville 5 – Marion	North-Central	$50.68/ft^2

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the average savings over the defined summer peak period, and is presented so that savings can be bid into PJM's Forward Capacity Market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[1732]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

= 72%[1733]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[1734]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[1735]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1736]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

[1732] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.
[1733] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.
[1734] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015
[1735] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1736] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \Delta kWh_{cooling} + \Delta kWh_{heating} + \Delta kWh_{fan}$$

$$\Delta kWh = CS_{cz} * Area_{window}$$

Where:

CS_{cz} = Annual heating, cooling + fan savings per area of window by climate zone, see Tables 5-7 below.

$Area_{window}$ = Total area of installed high performance windows. Use site specific value.

Table 5: Air Conditioner with Gas Furnace – electric savings per window area (kWh/ft²)[1737]

IL Degree-Day Zone	NC (IECC 2018)	NC (IECC 2021)	TOS or EREP: Double Pane	EREP: Single Pane
1 – Rockford	0.58	0.60	1.22	2.33
2 – Chicago	0.60	0.61	1.20	2.24
3 – Springfield	0.51	0.69	1.39	2.70
4 – Belleville	0.53	0.78	1.39	2.74

[1748] Ibid
[1749] Ibid

FOSSIL FUEL SAVINGS

$$\Delta Therms = HS_{cz} * Area_{window}$$

Where:

HS_{cz} = Annual heating savings per area of window by climate zone, see Table 12.

$Area_{window}$ = Total area of installed high performance windows. Use site specific value.

Table 12: Gas heating savings per window area by climate zone and baseline window condition (therm/ft^2)[1750]

IL Degree-Day Zone	NC (IECC2018)	NC (IECC 2021)	TOS or EREP: Double Pane	TOS or EREP: Single Pane
1 – Rockford	0.12	0.09	0.22	1.27
2 – Chicago	0.09	0.12	0.21	1.12
3 – Springfield	0.16	0.08	0.17	0.91
4 – Belleville	0.17	0.07	0.16	0.89
5 – Marion	0.14	0.06	0.16	0.73

For example, a single family residence in Rockford with a gas furnace and air conditioner replaces 10 existing double pane windows with HPW. Each window is 12 square feet, so the total window area is 120 square feet.

1st 13 years savings calculation:

$$\Delta Therms = 0.22 * 120 = 26.4\ therms$$

$$\Delta kWh = 1.22 * 120 = 146.4\ kWh$$

$$\Delta kW_{PJM} = \left(\frac{146.4}{512}\right) * 0.466 = 0.13\ kW$$

Remaining 27 years savings calculation:

$$\Delta Therms = 0.12 * 120 = 14.4\ therms$$

$$\Delta kWh = 0.58 * 120 = 69.6\ kWh$$

$$\Delta kW_{PJM} = \left(\frac{69.6}{512}\right) * 0.466 = 0.063\ kW$$

MEASURE CODE: RS-SHL-TTWI-V06-260101

REVIEW DEADLINE: 1/1/2028

5.6.9 Insulated Cellular Shades

DESCRIPTION

Insulating cellular shades greatly improve the thermal envelope performance compared to uncovered windows or conventional vinyl window coverings. These coverings have a honeycomb or cellular structure that can be operated manually or automated. Insulated cellular shades are considered to have the highest R-value among available blinds, shades, and other window coverings. They are designed with multiple layers of varying fabrics to trap air inside pockets that act as insulators and increase the R-value of the window covering and reduce the thermal heat transfer through windows.

The window's reduced heat loss has a significant impact on home energy savings as windows are often the weakest part of any building envelope. These products provide benefits for both heating and cooling seasons and for both natural gas and electric heated and cooled homes. They also have non-energy benefits such as, increased thermal comfort and decreased outside noise.

This measure was developed to be applicable to the following program types: TOS, NC. If applied to other program types, the measure savings should be verified

DEFINITION OF EFFICIENT EQUIPMENT

The efficient insulating cellular shades must be at least a double cell design installed on at least 75% of a home's windows. The Attachments Energy Rating Council (AERC) has a third party verified rating that has been developed for residential window attachments[1751]. If possible, utilizing the AERC rating system, eligible insulating cellular shades need to have a Cool Climate Rating greater or equal to 10 due to the Illinois climate.

DEFINITION OF BASELINE EQUIPMENT

The baseline for this measure is a home with uncovered windows or standard existing shades or blinds.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life is assumed to be 6 years[1752].

DEEMED MEASURE COST

The costs of window coverings vary greatly based on factors other than energy efficiency. The incremental cost of insulated cellular shades over standard window coverings is assumed to be $93 per shade or $1,397 per home[1753].

Loadshape R09 - Residential Electric Space Heat
Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)
= 68%[1754]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes

[1751] Attachments Energy Rating Council. May 01, 2022. www.https://aercenergyrating.org/
[1752] A review of online retailers, lifestyle and architectural blogs suggests that cellular (sometimes called honeycomb) shades have a slightly shorter lifespan on 5 to 7 years, this being due to their more complicated internal structure which quickly loses its insulating properties when damage is sustained
[1753] Review of leading internet retailers performed 7/18/2025 to determine average cost of single cellular window shade. Per home deemed measure cost assumes 15 windows per home.
[1754] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

(during system peak hour)

= 72%[1755]

$CF_{SSP, MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[1756]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[1757]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1758]

$CF_{PJM, MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (\Delta kWh_{_cooling} + \Delta kWh_{_heatingElectric} + \Delta kWh_{_heatingFurnace})$$

Where:

$\Delta kWh_{_Cooling}$ = If central cooling, reduction in annual cooling requirement due to cellular window shades

= FLH_{cool} * Capacity_cooling * ((1/ηCool)/1000) * ESF_{cool}

FLH_{cool} = Full load cooling hours

= Dependent on location as below:[1759]

Climate Zone (City based upon)	Single Family	Multifamily
1 (Rockford)	547	499

[1755] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[1756] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

[1757] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1758] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1759] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

Climate Zone (City based upon)	Single Family	Multifamily
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1082	982
5 (Marion)	956	868
Weighted Average[1760]		
ComEd	676	603
Ameren	875	791
Statewide	731	655

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

Capacity_cooling = Size of new equipment in Btu/hr (note 1 ton = 12,000Btu/hr)

= Use actual when program delivery allows size of AC unit to be known. If unknown, assume 33,600 Btu/hr for single family homes, 28,000 Btu/hr for multifamily, or 24,000 Btu/hr for mobile homes.[1761] If building type is unknown, assume 31,864Btu/hr.[1762]

ηCool = the cooling equipment's Seasonal Energy Efficiency Ratio rating (kBtu/kWh) * Distribution Efficiency

= Use actual SEER2 rating where it is possible to measure or reasonably estimate (assuming 85% distribution efficiency if only equipment efficiency is available). If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time[1763]. If unknown, use the following assumption (do not derate further by age):

Cooling System	SEER2[1764]	ηCool (SEER2 * 0.85)
Air Source Heat Pump	11.4	9.7
Central AC		

ESF_{cool} = Insulating cellular shades cooling energy savings factor

= 0.05[1765]

[1760] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[1761] Single family cooling capacity based on Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), October 19, 2010, ComEd, Navigant Consulting. Multifamily capacity based on weighted average of PY9 Ameren and ComEd MF cooling capacities. Mobile home capacity based on ENERGY STAR's Manufactured Home Cooling Equipment Sizing Guidelines which vary by climate zone and home size. The average size of a mobile home in the East North Central region (1,120 square feet) from the 2015 RECS data is used to calculated appropriate size.

[1762] Unknown is based on statewide weighted average of 69% single family and 31% multifamily, based on IL data from 2009 RECS Table HC2.9 Structural and Geographic Characteristics of Homes in Midwest Region, Divisions and States, 2009.

[1763] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1764] Estimate based upon Navigant, 2018 "EIA – Technology Forecast Updates – Residential and Commercial Building Technologies – Reference Case", converted to SEER2.

[1765] Average of HVAC savings for typical use compared to baseline conditions of no shades and common vinyl blinds. "Testing the Performance and Dynamic Control of Energy-Efficient Cellular Shades in the PNNL Lab Homes." PNNL. August 2018. Table 4.3 https://aercnet.org/wp-content/uploads/2018/10/Testing-the-Performance-and-Dynamic-Control-of-Energy-Efficient-Cellular-Shades-in-the-PNNL-Lab-Homes.pdf.

$\Delta kWh_{_Heating\ Electric}$ = If electric heat (resistance baseboard, electric furnace or heat pump), reduction in annual electric heating due to cellular window shades

= FLH_{heat} * Capacity_heating * 1/(3,412 * ηHeat) * ESF_{heat}

FLHheat = Full load heating hours

= Dependent on location as below:[1766]

Climate Zone (City based upon)	FLH_heat
1 (Rockford)	1924
2 (Chicago)	1726
3 (Springfield)	1708
4 (Belleville)	1195
5 (Marion/Murphysboro)	1270
Weighted Average[1767]	
ComEd	1766
Ameren	1547
Statewide	1700

Capacity_heating = Heating output capacity (Btu/hr) of electric heat

= Actual

ηHeat = Efficiency of heating system

= Actual (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1768] or if not available refer to default table below.[1769] If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85% for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) (HSPF2/3.412)*0.85
Heat Pump (if age unknown, assume 2006-2014)	Before 2006	5.8	1.44
	After 2006 -2014	6.5	1.62

[1766] Heating EFLH based on ENERGY STAR EFLH for Rockford, Chicago, and Springfield and on NCDC/NOAA HDD for the other two cities. In all cases, the hours were adjusted based on average natural gas heating consumption in IL. During update cycle for version v.12, applied percent change of HDD60, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHheat values

[1767] Weighting for Ameren is based on electric heat accounts in each of the heating zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[1768] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1769] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency) (HSPF2/3.412)*0.85

5.6.10 Multifamily Whole Building Aerosol Sealing

DESCRIPTION

Multifamily buildings have many of the same leakage paths as single-family homes, as well as additional paths hidden in shared walls or other cavities that are difficult to seal with conventional methods. Typically, shared walls between multifamily homes are difficult to air seal effectively, leading to issues when trying to meet code. This measure is the application of an aerosol sealant to a new or existing multifamily building. The aerosol envelope sealing technology uses an automated approach to produce extremely tight envelopes.

Air is blown into a multifamily unit while an aerosol sealant "fog" is released in the interior. As air escapes the building through leaks in the envelope, the sealant particles are carried to the leaks where they impact and stick to the edges of the leaks, eventually sealing them. A standard house or duct air leakage test fan is used to pressurize the building and provide real-time feedback and a permanent record of the sealing. The process is more effective and convenient than conventional sealing methods because it requires less time and effort, it can seal a larger portion of a leakage area more quickly, and can be used to meet more stringent compartmentalization requirements. It can be used to seal multiple units in a residential multi-family building in a cost-effective manner. Energy savings are estimated using EnergyPlus whole-building energy simulations.

This measure was developed to be applicable to the following program types: RF and NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Existing multifamily units which have been aerosol sealed that meet an air exchange rate of 3.0 ACH50 (air changes per hour) or lower. This meets the residential energy code tightness requirements[1784]. New multifamily units which have been aerosol sealed that meet an air exchange rate of 0.6 ACH50 (air changes per hour) or lower. This meets the Passive House tightness requirements.[1785]

DEFINITION OF BASELINE EQUIPMENT

Existing multifamily buildings that are undergoing a major envelope retrofit. The existing air leakage should be determined through approved and appropriate test methods using a blower door at 50 Pascals. Note that setting up a blower door is a required step in the aerosol sealing process.

The baseline for new construction buildings would be the applicable code for air exchange rate.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 20 years.[1786]

DEEMED MEASURE COST

The measure cost for this aerosol sealing technology is $0.50/sq.ft. of home size[1787].

Algorithm

CALCULATION OF ENERGY SAVINGS

Energy savings are estimated using EnergyPlus whole-building energy simulations.

It is important to note that the energy savings for multifamily whole-building sealing process cannot be estimated using a simple infiltration algorithm. This is because conversion of the measured building leakage (ACH50) to infiltration at natural conditions treats the entire building as a single zone and does not account for air movement between zones and housing units and also does not consider effects of mechanical ventilation. Therefore, whole building level energy modeling must be done to estimate energy savings.

Baseline and efficient energy models were developed in the referenced study for Minneapolis climate zone.[1788] The energy savings in this measure have been adjusted for the Illinois climate zones based on degree days.[1789] A multifamily building with six floors was modeled containing four housing units in each floor. Each modeled unit is 30 ft wide and 40 ft long with a floor area of 1,200 ft^2. The floor plan is the same for each of the six floors in the modeled building and is symmetric to minimize the effects of building orientation on the simulation results.

The heating system consists of a central boiler that served each apartment through terminal units. The boiler system is rated for 75% seasonal efficiency. Cooling is provided by window air conditioners. The independent variables include the building's physical characteristics and operating parameters of the ventilation systems. The dependent variables include building energy use, total outside air flow (e.g. infiltration and ventilation), and inter-zonal air flows (e.g. adjoining units and units to/from common spaces).

ELECTRIC ENERGY SAVINGS

There is minimal impact on the cooling energy savings.[1790] There is a slight increase in the cooling energy needed after sealing due to less infiltration to offset internal loads. Due to the relatively small impact on cooling, it is not considered to be significant.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

The natural gas space heating savings are dependent on the ventilation system and whether the multifamily unit is existing or new construction.

Four types of continuous ventilation schemes were modeled for the apartments.

a) Exhaust Only: Exhaust fan in each unit with no direct supply of outdoor air. Consists of a single fan connected to a centrally located, single exhaust point in the house.
b) Exhaust and Half Supply: Ventilation scheme having both exhaust and supply ventilation systems. Full capacity exhaust fan in each unit with supply ventilation to the unit that is approximately half the exhaust capacity.
c) Balanced: A balanced ventilation system that has two fans and two duct systems. They introduce and exhaust approximately equal quantities of fresh outside air and polluted inside air.
d) No Ventilation: No continuous or intermittent mechanical ventilation. This is the most common type of

5.6.11 Insulated Concrete Forms

DESCRIPTION

Insulated Concrete Forms (ICFs) are building assembly blocks that are used to construct walls of a building both above grade and below grade walls. They are made of lightweight, hollow foam blocks with reinforced steel bars that are filled with concrete. The foam blocks provide insulation, while the concrete provides strength and durability. ICFs are a popular construction method for energy-efficient and passive buildings because they provide excellent insulation, which can result in lower energy costs and a more comfortable living environment. They also have good soundproofing properties and can be used in areas with high wind and seismic activity. ICFs are easy to work with and can be assembled to fit the specific needs of a building. Additionally, ICFs are durable and long-lasting, and they require minimal maintenance over time.

Energy saving potential of ICFs walls when compared to traditional building wall construction assemblies, across residential building types is detailed in this measure. When considering a building material for both above grade and below grade (basement) walls, insulated concrete forms provide a high effective thermal resistance (R-value) and it eliminates the requirement of any additional insulation material. Heating and cooling energy reductions are derived from higher and continuous thermal resistance provided by ICFs walls leading to reduction in overall heating and cooling loads.

This measure was developed to be applicable to the following program types: NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

ICFs assembly consist of a system of expanded or extruded polystyrene rigid insulation blocks separated by plastic webbing. Reinforcement bars are placed in the openings between the forms and concrete is poured and sandwiched between two layers of insulation material. The assembly provides continuous insulation and thermal mass across the building envelope. Effective thermal resistance R-values of the ICFs walls assembly are manufacturer published values to be used as a part of the measure. ICFs walls to be considered in this measure should have assembly U-values that shall exceed minimum required assembly R-values as defined by International Energy Efficiency Code[1792], listed below. A heated basement condition shall be required to utilize measure savings in below grade applications.

ICF Above grade wall assembly R-value >22.2 (hr $ft^2°\mathrm{F}/Btu$)

ICF Below grade wall assembly R-value > 20 (hr $ft^2°\mathrm{F}/Btu$)

DEFINITION OF BASELINE EQUIPMENT

Widely prevalent traditional building wall construction types[1793] [1794] listed in table below are considered as baseline for this measure. Thermal resistance R-values corresponding to code required thermal transmittance U-value listed in 2021 International energy conservation code. These values are to be used in prescriptive energy saving calculation methodology.

[1792] 2021 International Energy Efficiency Code, Chapter 4 Residential energy efficiency, section R402, table R402.1.2. Minimum assembly R values are calculated from listed assembly maximum U values for wooden frame and basement walls.

[1793] U.S. Building Stock Characterization Study by National Renewable Energy Laboratory. US Building Typology Segmentation Residential | Tableau Public. Data shows that 84% of the single-family homes and 30-74% of Multifamily homes in Illinois are built with wood frame construction since the 1980s.

[1794] A technology report from Portland Cement Association briefs[1794], lists Concrete as the most common product of choice for basement construction with 98% of North American basements built of one of many available concrete wall systems. Concrete Basements| Concrete Construction Magazine

Wall Type	Type	Code	Zone	Assembly U-Value (Max.)	Corresponding Assembly R-Value (Min.)[1795]
Above grade wall	Wood Frame Wall	2021 IECC (Residential)	All	0.045	22.2
Below grade wall	Basement Wall		Zone 4	0.059	16.9
			Zone 5	0.05	20

Note: U Values and R values listed are in Imperial units. U-value: (Btu/hr ft^2°F), R-value: (hr ft^2°F/ Btu)

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life is assumed to be 50 years[1796].

DEEMED MEASURE COST

The actual capital cost for this measure should be used in screening. If unknown, use total measure cost listed in table below include the cost of ICF blocks, concrete, reinforcement materials and labor. Incremental costs are compared against a wood frame wall for above grade walls and a standard concrete wall for below grade walls. Manufacturer specified R-values of ICF block/panels and actual concrete type R values shall be used to calculate ICF assembly R-value.

ICF Core thickness[1797]	Total Measure cost[1798] ($/Square ft of wall area)	Incremental cost against above grade wood frame wall[1799] ($/Square ft of wall area)	Incremental cost against Basement concrete wall[1800] ($/Square ft of wall area)	ICF assembly R-Value [1801] [1802] (ft²·°F·h /BTU)
4”	12.14	6.58	6.94	23.9
6”	13.20	7.64	5.85	27.1
8”	16.37	10.81	8.34	28.4

LOADSHAPE

Loadshape R08 - Residential Cooling

[1795] 2021 International Energy conservation code (IECC) lists maximum allowable U-value for wood frame walls under residential energy efficiency section. Minimum required R-value is calculated as a reciprocal of the 2021 IECC listed U- value for wood frame walls. U-values correspond to climate zones 5A and 4C for Illinois.

[1796] While manufacturers claim the lifetime of the foam exceeds 100 years, due to likely degradation and or changes to the building shell over that timeframe, the TAC proposed a measure life of 50 years.

[1797] Core thickness indicate the space in between the EPS panels in ICF assembly.

[1798] Total measure costs include ICF blocks, concrete, rebar and labor costs. ICF block pricing information from ICF manufacturer Build Block and Fox blocks. Concrete costs and labor costs are from RSMeans 2023 residential cost database.

[1799] Baseline above grade wood frame wall cost include wall framing cost and code minimum insulation (cavity insulation and continuous insulation). These costs are referenced from 2023 RSMeans residential cost database.

[1800] Baseline basement wall costs include concrete, labor and code minimum insulation. These costs are referenced from 2023 RSMeans residential cost database.

[1801] National Concrete Masonry Association listed R-Value per thickness for different Concrete densities is utilized to calculated ICF assembly R-Values. A concrete density of 105 lb/ft^3 is assumed for calculation purpose. Actual Concrete R-Value should be used in the measure. R-VALUES AND U-FACTORS OF SINGLE WYTHE CONCRETE MASONRY WALLS - NCMA

[1802] An R-value of 4.2 ft²·°F·h /BTU-inch is used for calculating R-value of ICF blocks with a total thickness of 5.25”. ICF blocks from manufacturers Buildblock and Fox block are considered for this analysis.

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the average savings over the defined summer peak period and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1803]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

= 72%[1804]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[1805]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1806]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1807]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

[1803] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Following engineering algorithms can be used to calculate electric energy savings due to ICFs.

$$\Delta kWh = (\Delta kWh_{cooling} + \Delta kWh_{heatingElectric} + \Delta kWh_{heatingFurnace})$$

Where:

$\Delta kWh_{Cooling}$ = If central cooling, reduction in annual cooling requirement due to ICF insulation

= ((((1/R _base AG – 1/R_ICF_AG) * A_wall AG) * 24 * CDD65 * DUA * LoadFactor) / (1000 * ηCool)) * $ADJ_{WallCool}$ * %Cool

R_base AG = Thermal resistance R-value of the baseline above grade exterior wall assembly in IP units $ft^2 \cdot °F \cdot h/BTU$

= 22.2 $ft^2 \cdot °F \cdot h$ /BTU[1808]

R_ICF_AG = R_ICF block + R_Concrete + R_ ICF inserts

R_ICF block = Rated R-value of the wall assembly as provided by the manufacturer. IP units $ft^2 \cdot °F \cdot h/BTU$

= If unknown, Use R-Value per inch of ICF panel thickness[1809] of 4.2 h $ft^2 \cdot °F/BTU$-inch

R_Concrete = Actual R-value of the concrete used in the ICF assembly

= R-Value per inch * Concrete thickness, If unknown, use table below[1810] [1811]

Concrete density lb/ft^3	R-Value per inch
85	0.3
95	0.25
105	0.20
115	0.17
125	0.14
135	0.11
145	0.075

R_ ICF inserts = R-value of any additional ICF inserts/panels in the actual assembly

A wall AG = Net area of the above grade exterior wall envelope in ft^2.

DUA = Discretionary Use Adjustment (reflects the fact that people do not always operate their AC when conditions may call for it).
= 0.90[1812]

[1808] Calculated based on maximum assembly U-value requirement for a wood frame wall from 2021 IECC, Rmin=1/Umax, CHAPTER 4 [RE] RESIDENTIAL ENERGY EFFICIENCY, 2021 International Energy Conservation Code (IECC) | ICC Digital Codes (iccsafe.org)

2 (Chicago)	1047
3 (Springfield)	1183
4 (Belleville)	1641
5 (Marion/Murphysboro)	1450
Weighted Average[1815]	1098

ηCool = Seasonal Energy Efficiency Ratio of cooling system (kBtu/kWh) * Distribution Efficiency

= Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for central cooling with ducts if only equipment efficiency is available). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1816] or if unknown assume the following.[1817] If unknown value is used, it should not be derated by age.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3

Department of Commerce, Division of Energy. COMM-201305222-72623. To correct for the different climatological conditions in Minnesota and Illinois, the analysis includes 19 homes that have actual annual operating hours above 453 hrs/yr (over 1/2 of the actual annual operating hours for the highest operating hours home in the study-905 hrs/yr). Additionally, the factor is adjusted from 0.87 to 0.95 to account for the higher fraction of vacation homes in Minnesota compared to Illinois. See DUA_workbook_051525.xlsx for detailed data.

[1813] Based upon review of 102 room AC replacement projects completed in 2023 and 2024 for an Illinois multifamily energy efficiency program, the average room AC capacity installed was 11.41 MBh per living unit. From Section 5.3.3 for Central Air Conditioning, default central A/C capacity is 28 MBh. This results in a capacity scale factor of 11.41 / 28 = 0.41 when using room air conditioner cooling.

[1814] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 65°F.

[1815] Weighted based on number of occupied residential housing units in each zone (US Census 2010).

[1816] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1817] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time mean that using the minimum standard is appropriate. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Room AC[1818]		
Non-IQ	10.9	10.9
IQ	9.7	9.7
Unknown (for use in program evaluation only)[1819]		
Single Family Non-IQ		10.6
Single Family IQ		10.3
Multi Family Non-IQ		10.3
Multi Family IQ		9.9
Unknown		10.3

$ADJ_{WallCool}$ = Adjustment for cooling savings from wall insulation to account for inaccuracies in prescriptive engineering algorithms[1820]

= 75%

%Cool = Percent of homes that have cooling. Actual value shall be used.

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[1821]	98.9%	96.5%	99.8%	98.7%	98.6%

$\Delta kWh_{heatingElectric}$ = (((((1/R_base AG – 1/R_ICF_AG) * A_wall AG) +((1/R_base AG_basement – 1/R_ICF_AG_basement) *A_wall AG_basement) + ((1/R_base BG_basement – 1/R_ICF_BG_basement) *A_wall BG_basement)) * 24 * HDD60) / (3412 * ηHeat)) * $ADJ_{Wallheat}$ * %ElectricHeat

A_wall AG_basement = Net area of the above grade exterior basement wall envelope in ft^2

A_wall BG_basement = Net area of the below grade exterior basement wall envelope in ft^2

R_base AG_basement = R_basement wall

R_basement wall = Thermal resistance R-value of the baseline basement wall assembly in IP units $ft^2 \cdot °F \cdot h/BTU$

= 16.9 $ft^2 \cdot °F \cdot h/BTU$ for a basement wall in Climate zone 4 20 $ft^2 \cdot °F \cdot h/BTU$ for a basement wall in Climate zone 5[1822]

[1818] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[1819] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1820] As demonstrated in two years of metering evaluation by Opinion Dynamics, see Memo "Results for AIC PY6 HPwES Billing Analysis", dated February 20, 2015. TAC negotiated adjustment factor is 80%. During update cycle for version v.12, applied the percent change of NCEI Annual Normals CDD65 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all cooling-related adjustment values.

[1821] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1822] Calculated based on maximum assembly U-value requirement for a basement wall from 2021 IECC, Rmin = 1/Umax, International energy conservation code 2021, chapter 4 residential energy efficiency, table R402.1.4 equivalent U-factors.

R_ICF_AG_basement = R_ICF block + R_Concrete + R_ICF Inserts

R_base BG_basement = R_basement wall + R_earth average

R_earth average = Average R value of earth from table below

Below Grade R- Value[1823]									
Depth below grade (ft)	0	1	2	3	4	5	6	7	8
Average Earth R-value (ft^2·°F·h/BTU)	2.44	3.47	4.41	5.41	6.42	7.46	8.46	9.53	10.69

R_ICF_BG_basement = R_ICF block + R_Concrete + R_ICF Inserts + R_earth average

HDD60 = Heating degree days as listed in table below

Climate Zone	HDD60
1(Rockford)	5230
2(Chicago)	4798
3(Springfield)	4266
4(Belleville)	3188
5(Marion)	3390
Weighted Average[1824]	4631

3412 = Conversion factor from Btu to kWh

ηHeat = Efficiency of heating system

= Actual value or if known, refer to table below

System Type	Age of Equipment	HSPF2 Estimate	ηHeat (Effective COP Estimate * Distribution Efficiency)= (HSPF2/3.412)*0.85
Heat Pump (if age unknown assume 2006-2014)	Before 2006	5.8	1.44
	2006 - 2014	6.5	1.62
	2015 on	7.0	1.74
Resistance (Baseboard or Electric Furnace)	N/A	N/A	1.00
Unknown (for use in program evaluation only)[1825]	N/A	N/A	1.32

[1823] 2022 Illinois Statewide Technical reference manual for energy efficiency version 10.0, volume 3: Residential measures, 5.6.2 Basement sidewall insulation.

[1824] 2022 Illinois Statewide Technical reference manual for energy efficiency version 10, volume 3: Residential measures, 5.6.2 Basement sidewall insulation.

[1825] Calculation assumes 35% Heat Pump and 65% Resistance, which is based upon data from Energy Information Administration, 2009 Residential Energy Consumption Survey, see "HC6.9 Space Heating in Midwest Region.xls", using average for East North Central Region. Average efficiency of heat pump is based on assumption that 50% are units from before 2006 and 50% from 2006-2014. Program or evaluation data should be used to improve this assumption if available.

$ADJ_{Wallheat}$ = Adjustment for heating savings to account for inaccuracies in prescriptive engineering algorithms[1826]

=63%

%Electric Heat = Percent of homes that have electric space heating Actual value or Actual planned value during engineering design shall be used.

= 0 % for Natural Gas, 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump, Actual electric % value if both fuel sources are used.

= If unknown[1827], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[1828]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

$\Delta kWh_{heatingFurnace}$ = If furnace (fossil fueled or electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = ΔTherms * Fe * 29.3

If electric furnace: = $\Delta kWh_{heatingElectric} * F_e$

Fe = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[1829] [1830]

29.3 = kWh per therm

[1826] As demonstrated in two years of metering evaluation by Opinion Dynamics, see Memo "Results for AIC PY6 HPwES Billing Analysis", dated February 20, 2015. TAC negotiated adjustment factor is 60%. During update cycle for version v.12, applied the percent change of NCEI Annual Normals HDD60 from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) for all heating-related adjustment values.

[1827] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1828] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[1829] Fe is not one of the AHRI certified ratings provided for residential furnaces but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300-record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% Fe. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[1830] 2022 Illinois Statewide Technical reference manual for energy efficiency version 11.0, volume 3: Residential measures, 5.6.2 Basement sidewall insulation.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

ΔkW = (ΔkWh cooling / FLH cooling) * CF

Where:

FLH cooling = Full load hours of air conditioning

= Dependent on location:[1831]

Climate Zone (City based upon)	Single Family	Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1082	982
5 (Marion/Murphysboro)	956	868
Weighted Average[1832] ComEd Ameren Statewide	 676 875 731	 603 791 655

Use Multifamily if the building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[1833]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

= 72%[1834]

$CF_{SSP,\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[1835]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

[1831] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. During update cycle for version v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[1832] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[1833] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[1834] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[1835] Multifamily coincidence factors both from; *All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems*, Cadmus, October 2015

= 46.6%[1836]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1837]

$CF_{PJM,\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5%

FOSSIL FUEL SAVINGS

$$\Delta Therms = ((((1/R_base\ AG - 1/R_ICF_AG) * A\ wall\ AG) + ((1/R_base\ BG - 1/R_ICF_BG) * A\ wall\ BG) * 24 * HDD65) / (\eta Heat * 100{,}000\ Btu/therm)) * ADJ_{wallheat} * \%FossilHeat$$

Where:

ηheat = Efficiency of the heating system

= Actual or if known use values from table below

Equipment type	Age of equipment	AFUE[1838]
Gas Furnaces	After 11/19/2015	80%
Gas fired hot water Boilers	After 1/15/2021	84%
	9/1/2012- 1/15/2021	82%
Gas fired steam Boilers	After 1/15/2021	82%
	9/1/2012- 1/15/2021	80%

$ADJ_{Wallheat}$ = Adjustment for heating savings to account for inaccuracies in prescriptive engineering algorithms[1839]

= 60%

%FossilHeat = Percent of homes that have gas space heating. Actual value or Actual planned value during engineering design shall be used.

= 100 % for Natural Gas, 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump, Actual gas % value if both fuel sources are used.

= If unknown[1840], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%

[1836] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1837] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.
[1838] Code of federal regulations, title 10, chapter ii, subchapter D, part 430, subpart C Energy and water conservation standards. eCFR :: 10 CFR Part 430 Subpart C -- Energy and Water Conservation Standards
[1839] As demonstrated in two years of metering evaluation by Opinion Dynamics, see Memo "Results for AIC PY6 HPwES Billing Analysis", dated February 20, 2015. TAC negotiated adjustment factor is 60%.
[1840] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[1841]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

For Example, a one-story single-family home in Chicago with above ground wall area of 1,500 square feet and basement 8 feet completely below ground with a wall area of 1000 square feet is built with ICF construction with R-33 ICF blocks with 6" core thickness and concrete R-value per inch of 0.2 $ft^2 \cdot °F \cdot h$/BTU-inch. The home has a 13.4 SEER Central AC and 2.2 COP Heat pump.

ΔkWh Cooling = {[((1/R _base AG – 1/R_ICF_AG) * A_wall AG) * 24 * CDD65 * DUA] / (1000 * ηCool)} * $ADJ_{WallCool}$ * %Cool

ΔkWh Cooling ={[((1/22.2 - 1/(33+(6*0.2)))*1,500)*24*1047*0.95]/(1,000*13.2)}*0.75*1

= 30.46 kWh

ΔkWh heating ={[(((1/22.2 - 1/(33+(6*0.2)))*1,500)+ ((1/(20+10.69) - 1/(34.2+10.69)))*1000))*24*4798]/(3412*2.2)}*0.63*1

=328.74 kWh

ΔkWh Savings =30.46 + 328.74

= 359.2 kWh

Summer coincident peak demand savings during system peak hour

ΔkW_{SSP} =(30.46/709)*0.68

=0.029 kW

Summer coincident peak demand savings (Average during peak period)

ΔkW_{PJM} =(30.46/709)*0.466

=0.020 kW

For the same example with a Natural gas furnace with 80% efficiency for heating,

ΔTherms ={[(((1/22.2 - 1/(33+(6*0.2)))*1,500)+ ((1/(20+10.69) - 1/(34.2+10.69)))*1000))*24*4798]/(100,000*0.8)}*0.63*1

=30.85 Therms

ΔkWh heating Gas = 30.85*0.0314*29.3

=28.4 kWh

[1841] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

REVIEW DEADLINE: 1/1/2030

5.6.12 Energy Efficient Doors

DESCRIPTION

Energy efficient doors are designed to reduce heat transfer and air leakage in and out of buildings and contribute to the thermal performance of the building envelope.[1842] They employ materials and construction techniques that improve air sealing and insulation. For the purposes of this measure, a door is defined as an assembled unit consisting of door panel (with or without glazing), frame, sill, weatherstripping, corner pads, hinges, and trim, designed for a vertical installation in an external wall of a residential building. To be eligible, the door must serve as a barrier between conditioned and unconditioned space. When installed correctly, energy efficient doors help homes save energy and improve occupant comfort.

A conditioned space is defined as a space within the thermal envelope[1843] of the building that is intentionally heated or cooled for occupancy (bedrooms, living room, bathrooms, kitchen, etc.). A non-conditioned space is defined as a space outside of the thermal envelope of the building that is not intentionally heated or cooled for occupancy. A semi-conditioned space is defined as a space within the thermal envelope that is not intentionally heated or cooled for occupancy (unfinished basement).

This measure was developed for the following program types: New Construction (NC), Time of Sale (TOS), and Early Replacement (EREP). If applied to other program types, the measure savings should be verified.

This measure is applicable to the following door types:[1844]

- Swinging Exterior Doors, e.g. a home's main entry door.
- Sliding Glass Doors, e.g. a patio door
- Garage Doors, i.e. overhead or swinging doors designed to provide ingress/egress for motor vehicles.

By default, any "standard" door replacement (i.e. replacing an existing exterior door of the same size with no structural changes to the building) should be considered TOS/EREP for savings purposes unless the local code is explicitly triggered, in which case NC savings values shall be used.

DEFINITION OF EFFICIENT EQUIPMENT

Performance criteria for Swinging Exterior Doors and Sliding Glass Doors are based on the amount of glazing and ratings certified by the National Fenestration Rating Council (NFRC). Energy efficient doors meet ENERGY STAR® [1845] version 7.0 performance specifications shown below:

Table 1: Product Criteria for Energy Efficient Doors

IL Degree-Day Zone	Energy Star Climate Zone	Glazing Level	U-Value	SHGC
All	All	Opaque	≤ 0.17	No Rating
All	All	≤ ½ Lite	≤ 0.23	≤ 0.23
1 - Rockford 2 - Chicago 3 - Springfield	Northern	> ½ Lite	≤ 0.26	≤ 0.40
4 - Belleville 5 - Marion	North Central			

Energy efficient doors achieve these performance specifications by incorporating improved materials such as

[1842] Vivien L. Lu, Xi Chen, Jianheng Chen, Kai Jiao (Eds.), Toward Energy-Efficient Buildings, Elsevier, 2025, p.23

[1843] Thermal envelope refers to the shell of the building as a barrier to unwanted heat or mas transfer between the interior of the building and the outside conditions: IPCC, https://archive.ipcc.ch/publications_and_data/ar4/wg3/en/ch6s6-4-2.html

[1844] This list is based on the classification of door types in the National Fenestration Ratings Council list of rated products.

[1845] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

polyurethane foam core insulation, better seals and improved weather stripping, and multiple glass panes with low-e coatings and gas fills to improve thermal performance of the glazing elements.

Performance criteria for Garage Doors are based on ratings certified by either the Doors and Access Systems Manufacturers Association (DASMA) Thermal Performance Verification Program (TPVP)[1846], or the NFRC.

Table 2: Product Criteria for Energy Efficient Garage Doors

IL Degree-Day Zone	Energy Star Climate Zone	Glazing Level	U-Value	SHGC
All	All	<16%[1847]	≤ 0.30	No Rating

DEFINITION OF BASELINE EQUIPMENT

New Construction: As of January 1, 2024, opaque doors and sliding glass doors must meet the maximum U-Factors specified by the 2021 International Energy Conservation Code (IECC), as provided in the table below.

Table 3: Maximum U-factor for Door Assemblies

IL Degree-Day Zone	Energy Star Climate Zone	Glazing Level	U-Value
1 - Rockford 2 - Chicago 3 - Springfield	Northern	All	0.30
4 - Belleville 5 - Marion	North Central		

For Early Replacement and Time of Sale in existing homes, actual U-factor ratings of the existing door should be used. If actual ratings are not available, default ratings are provided in the tables below.

Table 4: Default U-Factors for Glass Doors[1848]

Frame Type	Energy Star Climate Zone	Glass Door	
		Single Pane	Double Pane
Metal	All	1.20	0.80
Metal with Thermal Break	All	1.10	0.65
Non-metal or Metal Clad	All	0.95	0.55
Glazed Block	All	0.60	

Table 5: Default U-Factors for Opaque Doors[1849]

Frame Type	Opaque U-Factor
Uninsulated Metal	1.20
Uninsulated Metal (Rolling)	0.90
Insulated Metal (Other)	0.60

[1846] Doors and Access Systems Manufacturers Association (DASMA) Thermal Performance Verification Program (TPVP), https://www.dasma.com/thermal/

[1847] DASMA Technical Data Sheet #196, p. 5, https://www.dasma.com/wp-content/uploads/2025/01/TDS-196.pdf

[1848] 2021 International Energy Conservation Code (IECC), February 2025 Version, Table C303.1.3(1), https://codes.iccsafe.org/content/IECC2021V1.0/chapter-3-ce-general-requirements

[1849] 2021 International Energy Conservation Code (IECC), February 2025 Version, Table C303.1.3(2), https://codes.iccsafe.org/content/IECC2021V1.0/chapter-3-ce-general-requirements

Frame Type	Opaque U-Factor
Wood	0.50
Insulated, Non-metal edge, max 45% glazing (double pane)	0.35

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The measure life for entry and sliding patio doors is 25 years; for overhead garage doors, measure life is 30 years.[1850] Remaining measure life for entry and sliding glass patio doors is 8 years and 10 years for garage doors.[1851]

DEEMED MEASURE COST

Measure Costs are provided in the table below. For New Construction (NC) and Time of Sale (TOS), use incremental cost, which reflects equipment cost above baseline. For Early Replacement (EREP), use actual equipment and labor costs for installation, less the present value of the assumed deferred replacement cost. If actual costs are unknown, assume the defaults provided in the table.

Efficient Door Measure Cost[1852]

Door Type	Incremental Cost $/sqft	Full Material Cost (EREP)	Deferred Baseline Replacement Cost
Entry Door	$14.68	$1,251	$867
Sliding Glass Door	$3.85	$1,288	$1,125
Garage Door	$5.38	$1,626	$1,230

LOADSHAPE

Loadshape R08 - Residential Cooling
Loadshape R09 - Residential Electric Space Heat
Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the average savings over the defined summer peak period, and is presented so that savings can be bid into PJM's Forward Capacity Market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central or Room A/C (during utility peak hour)

= 68%[1853]

$CF_{SSP\ SF}$ = Summer System Peak Coincidence Factor for Heat Pumps in single-family homes (during system peak hour)

= 72%[1854]

[1850] U.S. Department of Housing and Urban Development, Estimated Useful Life Table for Capital Needs Assessments, p. 7, online at https://www.hud.gov/sites/documents/eul_for_cna_e_tool.pdf

[1851] Assumed to be one third of effective useful life. For future TRM versions, recommend RUL be informed from program research.

[1852] Cost information averaged from a range of common sizes, obtained from web-based cost calculators based on surveys of popular, stocked products available at home improvement retailers, online at https://www.homewyse.com/costs/ (last accessed 8/18/2025).

[1853] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[1854] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

$CF_{SSP\ MF}$ = Summer System Peak Coincidence Factor for Heat Pumps in multi-family homes (during system peak hour)

= 67%[1855]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central or Room A/C (average during PJM peak period)

= 46.6%[1856]

$CF_{PJM\ SF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in single-family homes (average during PJM peak period)

= 46.6%[1857]

$CF_{PJM\ MF}$ = PJM Summer Peak Coincidence Factor for Heat Pumps in multi-family homes (average during peak period)

= 28.5% [1858]

Algorithm

CALCULATION OF ENERGY SAVINGS

The savings algorithm provided below uses U-Factor ratings differential to calculate energy savings from installing energy efficient doors. This method does not consider reductions in infiltration or solar heat gain. A modeled approach may be used to calculate savings inclusive of these factors.

This measure includes doors that separate conditioned space from outside air, as well as doors that separate conditioned space from space enclosed space within a dwelling that is not actively conditioned (e.g., a door that separates an unconditioned garage from a conditioned basement or other living area), and doors that separate outside air from interior space that is not actively conditioned (e.g. a door to an unheated garage, or a walk-out door for a semi-conditioned basement.

Energy savings calculations for doors separating conditioned space from outside air should use the CDD65 and HDD60 degree day values provided in the tables below. All other cases should use the CDD75 and HDD50 values. This accounts for the reduced (but not zero) heat transfer from semi-or nonconditioned enclosed spaces within a dwelling to outside air.

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = \Delta kWh_{cooling} + \Delta kWh_{heatingElectric} + \Delta kWh_{FurnaceFan}$$

$\Delta kWh_{cooling}$ = $(((U_{base} - U_{ee}) \times SF) / (\eta Cool * 1000)) * CDD * 24 * DUA * LoadFactor * \%Cool$

$\Delta kWh_{heatingElectric}$ = $(((U_{base} - U_{ee}) \times SF) / (\eta Heat * 1000)) * HDD * 24 * \%ElectricHeat$

$\Delta kWh_{FurnaceFan}$ = If *furnace* (fossil fueled or electric) heat, kWh savings for reduction in fan run time

If fossil fueled furnace: = $\Delta Therms * F_e * 29.3$

[1855] Multifamily coincidence factors both from; All-Electric Homes PY6 Metering Results: Multifamily HVAC Systems, Cadmus, October 2015

[1856] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

[1857] Ibid.

[1858] Ibid.

If electric furnace: $= \Delta kWh_{heatingElectric} * F_e$

Where

U_{base} = Baseline door U-Factor

= As provided above

U_{ee} = Efficient door U-Factor

= Actual

SF = Square footage of door

= Actual

ηCool = Seasonal Energy Efficiency Ratio of cooling system (kBtu/kWh) * Distribution Efficiency

Actual (where it is possible to measure or reasonably estimate, assuming 85% distribution efficiency for central cooling with ducts if only equipment efficiency is available). Note where new HVAC is installed in addition to door measures, the old HVAC unit efficiency should be used and the door measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1859] or if unknown assume the following.[1860] If unknown value is used, it should not be derated by age.

Age of Equipment	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Before 2006	9.5	8.1
2006 - 2014	12.4	10.5
Central AC After 1/1/2015	12.4	10.5
Heat Pump After 1/1/2015	13.3	11.3
Room AC[1861]		
Non-IQ	10.9	10.9
IQ	9.7	9.7
Unknown (for use in program evaluation only)[1862]		
Single Family Non-IQ		10.6
Single Family IQ		10.3
Multi Family Non-IQ		10.3
Multi Family IQ		9.9
Unknown		10.3

CDD = Cooling Degree Days. Dependent on location and whether the door separates conditioned space from outside air or an enclosed space not actively conditioned:

[1859] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1860] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Central AC was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely degradation of efficiencies over time means that using the minimum standard is appropriate. Note all ratings have been converted to SEER2 equivalents – since the new rating better reflects the actual efficiency of the units.

[1861] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[1862] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

IL Climate Zone	Conditioned CDD 65	Unconditioned CDD 75
1 (Rockford)	877	326
2 (Chicago)	1047	354

ηHeat = Efficiency of heating system, HSPF2

= Actual Heating Efficiency * Distribution Efficiency (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1867] or if not available refer to default table below.[1868] If unknown value is used, it should not be derated by age. If actual

[1863] Weighted based on number of occupied residential housing units in each zone (US Census 2010)

[1864]This factor utilizes data from a metering study: Pigg, Scott, D. Cautley, and K. Koski, (2016). "Improving Installation and Maintenance Practices for Minnesota Residential Furnaces, Air Conditioners and Heat Pumps", prepared for Minnesota Department of Commerce, Division of Energy. COMM-201305222-72623. To correct for the different climatological conditions in Minnesota and Illinois, the analysis includes 19 homes that have actual annual operating hours above 453 hrs/yr (over ½ of the actual annual operating hours for the highest operating hours homes in the study-905 hrs/yr). Additionally, the factor is adjusted from 0.87 to 0.90 to account for Illinois' hotter climate and higher number of muggy days. See DUA_Workbook_051525.xlsx for detailed data.

[1865] Based upon review of 102 room AC replacement projects completed in 2023 and 2024 for an Illinois multifamily energy efficiency program, the average room AC capacity installed was 11.41 MBh per living unit. From Section 5.3.3 for Central Air Conditioning, default central A/C capacity is 28 MBh. This results in a capacity scale factor of 11.41 / 28 = 0.41 when using room air conditioner cooling.

[1866] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1867] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1868] These default system efficiencies are based on the applicable minimum Federal Standards. In 2006 the Federal Standard for Heat Pumps was adjusted. While one would expect the average system efficiency to be higher than this minimum, the likely

Distribution Efficiency is not available, use 85% for heat pumps.

System Type	Age of Equipment	HSPF2 Estimate
Heat Pump	Before 2006	5.8
	2006-2014	6.5
	Since 2015	7
Resistance	N/A	3.412
Unknown (for use in program evaluation only)	N/A	5.3

HDD = Heating Degree Days. Dependent on location and whether the door separates conditioned space from outside air or an enclosed space not actively conditioned:

IL Climate Zone	Conditioned HDD 60	Unconditioned HDD 50

2 (Chicago)	4798	2845
3 (Springfield)	4266	2456
4 (Belleville)	3188	1651
5 (Marion)	3390	1750
Weighted Average[1869]	4631	2732

%ElectricHeat = Percent of homes that have electric space heating

= 100% for Electric Resistance or Heat Pump

= 0% for Fossil fuel heating

= If unknown, [1870] use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[1871]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above

degradation of efficiencies over time means that using the minimum standard is appropriate. An 85% distribution efficiency is then applied to account for duct losses for heat pumps. Note all ratings have been converted to HSPF2 equivalents – since the new rating better reflects the actual efficiency of the units.

[1869] Weighted based on number of occupied residential housing units in each zone (US Census 2010)

[1870] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1871] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Fe = Furnace Fan energy consumption as a percentage of annual fuel consumption

= 3.14%[1872]

29.3 = kWh per therm

For example, a new 6 ft by 8 ft sliding glass patio door, with a U-Factor of 0.23, is installed in a Springfield single family home with Central AC, replacing a single-pane metal framed glass patio door.

$\Delta kWh = \Delta kWh_{cooling} + \Delta kWh_{heating} + \Delta kWh_{FurnaceFan}$

$\Delta kWh_{cooling} = (((1.20 – 0.23) \times 48) / (12.4 * 1000)) * 1183 * 24 * 0.75 * 100\%$
$= 79.95$

$\Delta kWh_{heating} = (((1.20 – 0.23) \times 48) / (6.5 * 1000)) * 4266 * 24 * 18\%$
$= 132.01$

$\Delta kWh_{FurnaceFan} = 6.01 * 3.14\% * 29.3$
$= 5.53$

$\Delta kWh = 79.95 + 132.01 + 5.53$
$= 217.49$

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$\Delta kW = (\Delta kWh_cooling / FLH_cooling) * CF$

Where:

FLH_cooling = Full load hours of air conditioning
Dependent on location:

IL Climate Zone	Single Family	Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1082	982
5 (Marion)	956	868
Weighted Average[1873]		
ComEd	676	603
Ameren	875	791

[1872] F_e is not one of the AHRI certified ratings provided for residential furnaces, but can be reasonably estimated from a calculation based on the certified values for fuel energy (Ef in MMBtu/yr) and Eae (kWh/yr). An average of a 300 record sample (non-random) out of 1495 was 3.14%. This is, appropriately, ~50% greater than the ENERGY STAR version 3 criteria for 2% F_e. See "Programmable Thermostats Furnace Fan Analysis.xlsx" for reference.

[1873] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

IL Climate Zone	Single Family	Multifamily
Statewide	731	655

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

For example, a new 6 ft by 8 ft sliding glass patio door, with a U-Factor of 0.23, is installed in a Springfield single family home with Central AC, replacing a single-pane metal framed glass patio door.

ΔkW = (79.95 /779) * 68%
= 0.070

FOSSIL FUEL SAVINGS

$\Delta Therms = (((U_{base} – U_{ee}) \times SF) / (\eta Heat * 100{,}000)) * HDD * 24 * \%FossilHeat$

Where

ηHeat = Efficiency of heating system

= Equipment efficiency * distribution efficiency

= Actual (where it is possible to measure or reasonably estimate). Note where new HVAC is installed in addition to shell measures, the old HVAC unit efficiency should be used and the shell measure savings calculated first, the HVAC measure then assuming the reduced heat/cooling loads. If using rated efficiencies, derate efficiency value by 1% per year (maximum of 30 years) to account for degradation over time,[1874] or if unknown assume 72% for existing system efficiency[1875]. If unknown value is used, it should not be derated by age. If actual Distribution Efficiency is not available, use 85%.

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for Fossil Fuel heating

= 0 % for Electric Resistance or Heat Pump

= If unknown[1876], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[1877]					75.4%

[1874] Justification for degradation factors can be found on page 14 of 'AIC HVAC Metering Study Memo FINAL 2_28_2018'. Estimate efficiency as (Rated Efficiency * (1-0.01)^Equipment Age).

[1875] Based on average Nicor PY4 nameplate efficiencies derated by 15% for distribution losses.

[1876] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1877] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

Other factors as defined above.

For example, a new 6 ft by 8 ft sliding glass patio door, with a U-Factor of 0.23, is installed in a Springfield single family home with Central AC, replacing a single-pane metal framed glass patio door.

ΔTherms = (((1.20 – 0.23) x 48) / (6.5 * 100,000)) * 4266 * 24 * 82%

5.7 Miscellaneous

5.7.1 High Efficiency Pool Pumps

DESCRIPTION

Residential outdoor pool pumps can be single speed, two/multi speed or variable speed. A federal standard (82 FR 5650) effective July 19, 2021 , which requires new pumps to be at least two speed.

Single speed pumps are often oversized, and run frequently at constant flow regardless of load. Single speed pool pumps require that the motor be sized for the task that requires the highest speed. As such, energy is wasted performing low speed tasks at high speed. Two speed and variable speed pool pumps reduce speed when less flow is required, such as when filtering is needed but not cleaning, and have timers that encourage programming for fewer on-hours. Variable speed pool pumps use advanced motor technologies to achieve efficiency ratings of 90% while the average single speed pump will have efficiency ratings between 30% and 70%.[1878]

This measure is the characterization of the purchasing and installing of a new ENERGY STAR[1879] or CEE T1 variable speed residential pool pump motor in place of a new baseline pump meeting the federal standard for Time of Sale and New Construction, or the early replacement of a standard single speed motor of equivalent horsepower.

This measure was developed to be applicable to the following program types: TOS, NC, RF.

If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

The high efficiency equipment is an ENERGY STAR or CEE Tier residential pool pump meeting the ENERGY STAR minimum qualifications for either in-ground or above ground pools. ENERGY STAR version 3.0 specification takes effect on July 19, 2021. Note that for in ground pools, the CEE T1 level is the same as the new Federal Standard, and Tier 2 is the same as ENERGY STAR V3 for the standard size pumps, so savings for CEE T1 is only provided for above ground pools where there is an increment in efficiency.

Pump Sub-Type	Size Class	ENERGY STAR Version 3.1 Energy Efficiency Level	CEE Tier 1	CEE Tier 2
Self-Priming (Inground) Pool Pumps	Extra Small (hhp ≤ 0.13)	WEF ≥ 13.40	N/A	N/A
	Small (hhp > 0.13 and < 0.711)	WEF ≥ -2.45 x ln (hhp) + 8.40	WEF ≥ -1.30 x ln (hhp) + 4.95	WEF ≥ -2.83 x ln (hhp) + 8.84
	Standard Size (hhp ≥ 0.711)	WEF ≥ -2.45 x ln (hhp) + 8.40	WEF ≥ -2.3 x ln (hhp) + 6.59	WEF ≥ -2.45 x ln (hhp) + 8.4
Non-Self Priming (Aboveground) Pool Pumps	Extra Small (hhp ≤ 0.13)	WEF ≥ 4.92	N/A	N/A
	Standard Size (hhp > 0.13)	WEF ≥ -1.00 x ln (hhp) + 3.85	WEF ≥ -1.60 x ln (hhp) + 9.10	N/A

DEFINITION OF BASELINE EQUIPMENT

For TOS and NC, the baseline equipment is a two speed residential pool pump meeting the Federal Standard, provided below:

[1878] U.S. DOE, 2012. Measure Guideline: Replacing Single-Speed Pool Pumps with Variable Speed Pumps for Energy Savings. Report No. DOE/GO-102012-3534.

[1879] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

Pump Sub-Type	Size Class	Baseline
Self-Priming (Inground) Pool Pumps	Extra Small (hhp ≤ 0.13)	WEF ≥ 5.55
	Small (hhp > 0.13 and < 0.711)	WEF ≥ -1.30 x ln (hhp) + 2.90
	Standard Size (hhp ≥ 0.711)	WEF ≥ -2.30 x ln (hhp) + 6.59
Non-Self Priming (Aboveground) Pool Pumps	Extra Small (hhp ≤ 0.13)	WEF ≥ 4.60
	Standard Size (hhp > 0.13)	WEF ≥ -0.85 x ln (hhp) + 2.87

For early replacement, the baseline equipment is the existing single speed residential pool pump.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated useful life for a two speed or variable speed pool pump is 7 years.[1880]

DEEMED MEASURE COST

For TOS and NC, the incremental costs for ENERGY STAR in-ground pool pumps are estimated as $314[1881] and for above ground pool pumps are estimated as $930.[1882]

For early replacement, the full replacement costs shall be used. A deferred new baseline cost (after 4 years) of replacing the existing equipment should also be included.

LOADSHAPE

Loadshape R15 – Residential Pool Pumps

COINCIDENCE FACTOR

The coincidence factor for this measure is assumed to be 0.831.[1883]

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS[1884]

For TOS and NC:

$$\Delta kWh = (Gallons * Turnovers * (1/WEF_{base} - 1/WEF_{ESTAR}) * Days) / 1000$$

For Early Replacement:

$$\Delta kWh = (Gallons * Turnovers * (1/EF_{Exist} - 1/WEF_{ESTAR}) * Days) / 1000$$

Where:

Gallons = Capacity of the pool

[1880] As recommended in Navigant 'ComEd Effective Useful Life Research Report', May 2018.
[1881] ENERGY STAR Pool Pump Calculator and represent the difference between the two/multi speed incremental cost and the variable speed incremental cost.
[1882] CEE Efficient Residential Swimming Pool Initiative, December 2012, page 18 and represent the difference between the two/multi speed incremental cost and the variable speed incremental cost.
[1883] Based on assumptions of daily load pattern through pool season. Assumption was developed for Efficiency Vermont but is considered a reasonable estimate for Illinois.
[1884] The methodology followed is consistent with the most recent version of the 2020 ENERGY STAR calculator (Pool_Pump_Calculator_2020.05.05_FINAL.xls), however this has not been updated to account for the new federal standard.

= Actual. If unknown assume:

Pool Type	Gallons
In ground	22,000[1885]
Above ground	7,540[1886]

Turnovers = Desired number of pool water turnovers per day

= 2[1887]

WEF_{base} = Weighted Energy Factor of baseline pump (gal/Wh) [1888]

Pool Type	WEF_{Base}
In ground	4.75
Above ground	2.58

WEF_{ESTAR} = Weighted Energy Factor of ENERGY STAR pump (gal/Wh) [1889]

Pool Type	WEF_{EE}	
	ENERGY STAR	CEE Tier 1
In ground	6.44	N/A
Above ground	3.51	8.55

EF_{Exist} = Energy Factor of existing single speed pump (gal/Wh)

= 2.3[1890]

Days = Number of days per year that the swimming pool is operational

= 122[1891]

1,000 = Conversion factor from Wh to kWh

Based on the defaults provided above, the annual energy savings (ΔkWh) are detailed in the table below:

Pool Type	ΔkWh			
	TOS/NC		Retrofit	
	ENERGY STAR	CEE T1	ENERGY STAR	CEE T1
In ground	296.0	N/A	1528.1	N/A
Above ground	188.4	496.9	285.7	594.2

[1885] Consistent with assumption in the 2020 ENERGY STAR calculator.

[1886] Based on typical pool sizes from "Evaluation of Potential Best Management Practices - Pools, Spas, and Fountains, The California Urban Water Conservation Council", 2010.

[1887] Consistent with assumption in the 2020 ENERGY STAR calculator.

[1888] Based on applying the federal standard specifications to the average Curve-C rated hydraulic horsepower (hhp) from the ENERGY STAR Qualified Products List, accessed 5/03/2024.

[1889] Based on applying the ENERGY STAR and CEE Tier 1 specifications to the average Curve-C rated hydraulic horsepower (hhp) from the ENERGY STAR Qualified Products List, accessed 5/03/2024.

[1890] Consistent with assumption in the 2020 ENERGY STAR calculator, assuming 1.5 HP pump.

[1891] Consistent with assumption in the 2020 ENERGY STAR calculator.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

For TOS and NC:

$\Delta kW = ((kWh/day_{base})/(Hrs/day_{base}) – (kWh/day_{ESTAR})/(Hr/day_{ESTAR})) * CF$

For Early Replacement:

$\Delta kW = ((kWh/day_{Exist})/(Hrs/day_{Exist}) – (kWh/day_{ESTAR})/(Hr/day_{ESTAR})) * CF$

Where:

kWh/day = daily energy consumption of pool pump, as defined above.

= Actual, defaults provided below:

	ΔkWh/day			
Pool Type	**Base**	**ENERGY STAR**	**CEE T1**	**Exist**
In ground	9.3	6.8	N/A	19.4
Above ground	5.8	4.3	1.8	6.6

Hrs/day_{base} = daily run hours of pool pump

= (Gallons * Turnover) / GPM

		Weighted Average GPM[1892]	Hours/Day
In ground	Base	43.6	16.8
	Efficient	32.2	22.8
	Exist	78	9.4
Above ground	Base	44.7	5.6
	Efficient	27.3	9.2
	Exist	78.1	3.2

CF = Summer Peak Coincidence Factor for measure

= 0.831[1893]

Based on defaults provided above:

	ΔkW			
Pool Type	**TOS/NC**		**Retrofit**	
	ENERGY STAR	**CEE T1**	**ENERGY STAR**	**CEE T1**
In ground	0.2087	N/A	1.4689	N/A
Above ground	0.4770	0.7059	1.3300	1.5590

Mid-Life Baseline Adjustment

For early replacement measures, to account for the fact that the existing pump would have needed to be replaced

[1892] The 2013 ENERGY STAR calculator provided high and low flow and hour assumptions for multi and variable speed pumps. This is used to estimate a weighted average GPM assumption, see 'IL TRM_Pool Pump Calculator_2024.xls'.

[1893] Based on assumptions of daily load pattern through pool season. Assumption was developed for Efficiency Vermont but is considered a reasonable estimate for Illinois.

within the lifetime of the measure, a mid-life adjustment should be applied. This is calculated as the savings from the federal standard to the ESTAR pump divided by the savings from the existing pump. This should be applied after 4 years.

Based on defaults provided above:

Pool Type	Adjustment Factor applied to Annual kWh Savings	
	ENERGY STAR	CEE T1
In ground	19%	N/A
Above ground	66%	84%

5.7.2 Low Flow Toilets

DESCRIPTION

The first federal standards dealing with water consumption for toilets was the Energy Policy Act of 1992. It specified a gallon per flush (gpf) standard for both fixtures. These standards are used to define the baseline equipment for this measure. The Subsequent U.S. EPA WaterSense program in 2009 set even tighter standards for plumbing fixtures, including toilets. These standards are used to define the efficient equipment for this measure.

DEFINITION OF EFFICIENT EQUIPMENT

The high efficiency equipment is a U.S. EPA WaterSense certified residential toilet fixture.

DEFINITION OF BASELINE EQUIPMENT

The baseline equipment is a toilet that has a maximum gallons per flush outlined by the Energy Policy Act of 1992.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The estimated useful life for this measure is assumed to be 25 years.[1894]

DEEMED MEASURE COST

The incremental costs for both are $0.[1895]

LOADSHAPE

Loadshape R03 - Residential Electric DHW

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

The following savings should be included in the total savings for this measure, but should not be included in TRC tests to avoid double counting the economic benefit of water savings.

$$\Delta kWh = \Delta Water / 1{,}000{,}000 * Ewater\ total$$

Ewater = IL Total Water Energy Factor (kWh/Million Gallons)

= 5,010[1896]

[1894] http://www.metrohome.us/information_kit_files/life.pdf and ATD Home Inspection: http://www.atdhomeinspection.com/advice/average-product-life/ is 50 years. 25 years is used to be conservative.

[1895] Measure cost assumption from City of Fort Collins, "Green Building Practice Summary," March 21, 2011, page 2. The document states "Information from the EPA WaterSense web site: WaterSense® labeled toilets are not more expensive than regular toilets. MaP testing results have shown no correlation between price and performance. Prices for toilets can range from less than $100 to more than $1,000. Much of the variability in price is due to style, not functional design."

[1896] This factor includes 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

Toilet Calculation

For example, a low flow toilet is installed in a single family home with unknown occupancy.

ΔkWh = 1495 / 1,000,000 * 5,010

= 7.5 kWh/year

SUMMER COINCIDENT PEAK DEMAND SAVINGS

N/A

FOSSIL FUEL SAVINGS

N/A

WATER IMPACT DESCRIPTIONS AND CALCULATION

$$\Delta Water = (GPF_{Base} - GPF_{Eff}) * NFPD * Household * ADPY$$

Where:

GPF_{Base} = Baseline equipment gallons per flush

= 1.6 for toilets[1897]

GPF_{Eff} = Efficient equipment gallons per flush

= 1.28 for toilets[1898]

NFPD = Number of flushes per day per occupant

= 5 [1899]

Household = Number of people in the houshold.

= Actual. If unknown assume average number of people per household:

Household Unit Type	Household[1900]		
	IQ Participants	Non-IQ Participants	All Participants
Single-Family - Deemed	2.76	2.62	2.67
Multifamily - Deemed	2.3	2.09	2.18
Household type unknown			2.46[1901]
Custom	Actual Occupancy or Number of Bedrooms[1902]		

Use Multifamily if: Building meets utility's definition for multifamily

ADPY = Annual days per year

= 365 for residential

[1897] U. S. EPA WaterSense. "Water Efficiency Management Guide – Bathroom Suite" (EPA 832-F-17-016d), Nov 2017.
[1898] U. S. EPA WaterSense. "Water Efficiency Management Guide – Bathroom Suite" (EPA 832-F-17-016d), Nov 2017.
[1899] U.S. EPA WaterSense, "Water Specification for Flushing Urinals Supporting Statement." Appendix B: References for Calculation Assumptions.
[1900] Assumptions are taken from the draft unadjusted 2024 Baseline Study evaluation data provided in 07/2024 by GDS Associates.
[1901] "Unknown" is based on statewide weighted average of 57% single family and 43% multifamily, based on IL data from 2020 RECS "Highlights of Structural Characteristics of U.S. Homes by State", IL data shows 57% of homes are single family detached.
[1902] Bedrooms are suitable proxies for household occupancy, and may be preferable to actual occupancy due to turnover rates in residency and non-adult population impacts.

Toilet Calculation

For example, a low flow toilet is installed in a single family IQ home with unknown occupancy.

$$\Delta Water = (1.6 – 1.28) * 5 * 2.76 * 365$$

$$= 1612 \text{ gal/year}$$

5.7.3 Level 2 Electric Vehicle Charger

DESCRIPTION

The measure is for the purchase of a Level 2 electric vehicle charger consistent with the ENERGY STAR[1903] specification for Electric Vehicle Supply Equipment (EVSE) installed for residential household use. Networked chargers enable access to online energy management tools through an EVSE network. Non-networked chargers are standalone units that are not connected to other units through an EVSE network.

This measure was developed to be applicable to the following program types: TOS. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

An ENERGY STAR qualified networked or non-networked level 2 electric vehicle charger.

DEFINITION OF BASELINE EQUIPMENT

A non-ENERGY STAR networked or non-networked level 2 electric vehicle charger.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected measure life for the EV charger is assumed to be 10 years.[1904]

DEEMED MEASURE COST

The incremental cost for the EV charger is assumed to be $84 for a non-networked charger and $47 for a networked charger.[1905]

LOADSHAPE

Loadshape R19 - Residential Electric Vehicle Charger

COINCIDENCE FACTOR

Coincidence factor is embedded in deemed demand reduction savings estimate, so the coincidence factor is assumed to be 1.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = (((Hours_PS + Hours_US) * SP_base) - (Hours_PS * SP_EEp + Hours_US * SP_EEu))/ 1000)$$

Where:

Hours_C = Annual Active Charging Hours

= 278 hours[1906]

[1903] In the event that the ENERGY STAR program is ended, the last effective ENERGY STAR specification should continue to be used through the effective period of this TRM.

5.7.4 Heat Pump Swimming Pool Heater

DESCRIPTION

This measure is applicable to electric heat pump pool heaters in residential applications. Heat pumps capture heat and move it from one place to another. The saving equations presented herein comprise three aspects of pool heating: convective heat loss via pool surface area due to water and air temperature differential, initial heat of full pool volume for seasonal pool use and reheat of pool refill on year round pools, and the heating of added pool water to offset water loss through evaporation.[1911] This measure applies to replacing either a gas-fired pool heater or a an electric resistance pool heater. If baseline equipment is a gas-fired pool heater, electric energy impacts result in additional electrical usage, but lower overall site energy usage.

This measure is only applicable to inground or outdoor single family home pools and is not applicable to spas. This measure is not applicable to community pools in multifamily housing complexes.[1912]

This measure was developed to be applicable to the following program types: TOS, NC, EREP.

DEFINITION OF EFFICIENT EQUIPMENT

The efficient equipment is defined as a heat pump that is more efficient than Illinois energy code. This type of heat pump is designed to heat pool water for residential sized pools. Compliance condition of the equipment is that it is an AHRI-certified heat pump pool heater.

DEFINITION OF BASELINE EQUIPMENT

The baseline reflects the existing pool water heater which could be natural gas, electric resistance or a less electric efficient heat pump water heater. The baseline equipment must be less efficient than that new equipment.

Heating Type	Heat Pump Efficiency
Natural Gas	82% Thermal Efficiency[1913]
Electric Resistance	100%
Heat Pump	3.5 COP

The California Appliance Efficiency Regulations (Title 20) requires a minimum coefficient of performance (COP) of 3.5 for heat pump pool heaters and a minimum thermal efficiency (TE) of 82% for all natural residential pool water heaters.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

15 years.[1914]

DEEMED MEASURE COST

Estimated gross and incremental installation costs are listed below.[1915] Costs include material cost of heat pump, infrastructure for installation, and labor.

[1911] ASHRAE Handbook: HVAC Applications, 2019, pg 51.25. ASHRAE states that except in aboveground pools and rare cases where cold groundwater flows past the pool walls, conductive losses through pool walls are small and can be ignored. ASRHAE additionally indicates that radiation losses that occur due to sky temperature differentials at night may be offset by solar heat gains of an unshaded pool during the day.

[1912] New York Standard Approach for Estimating Energy Savings from Energy Efficiency Programs – Residential, Multi-family, and Commercial/Industrial Measures Version 9

Equipment Type	Gross Cost	Incremental Cost
Gas Heater	$5,158	N/A
Heat Pump Heater	$7,074	$1,916

LOADSHAPE

Loadshape R15 - Residential Pool Pumps

COINCIDENCE FACTOR

The prescribed value for the coincidence factor is 0 for outdoor pools and is 0.8 for indoor pools.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Non fuel switch measures:

Net site energy consumed at the site is calculated below:

$$\Delta kWh = \frac{\left(BTU_{Surface} + BTU_{Reheat} + BTU_{Evap}\right)}{3{,}412} * \left[\left(\frac{F_{fuel\ baseline}}{E_{t,baseline}}\right) + \left(\frac{F_{elec,baseline}}{COP_{baseline}} - \frac{1}{COP_{ee}}\right)\right]$$

Fuel switch measures:

Fuel switch measures must produce positive total lifecycle energy savings (i.e., reduction in Btus at the premises) in order to qualify. This is determined as follows:

SiteEnergySavings (MMBTUs) = [FossilHeatReplaced] – [ElectricHeatAdded]

$$\text{FossilHeatReplaced} = \frac{\left(BTU_{Surface}+BTU_{Reheat}+BTU_{Evap}\right)}{1{,}000{,}000} * \left[\left(\frac{F_{fuel\ baseline}}{E_{t,baseline}}\right)\right]$$

$$\text{ElectricHeatAdded} = \frac{\left(BTU_{Surface}+BTU_{Reheat}+BTU_{Evap}\right)}{1{,}000{,}000} * \left[\left(\frac{F_{fuel\ baseline}}{E_{t,baseline}}\right) + \left(\frac{F_{elec,baseline}}{COP_{baseline}} - \frac{1}{COP_{ee}}\right)\right]$$

If SiteEnergySavings calculated above is positive, the measure is eligible.

The appropriate savings claim is dependent on which utilities are supporting the measure as provided in a table below:

Measure supported by:	Electric Utility claims (kWh):	Gas Utility claims (therms):
Electric utility only	SiteEnergySavings * 1,000,000/3,412	N/A
Electric and gas utility (Note utilities may make alternative agreements to how savings are allocated as long as total MMBtu savings remains the same).	%IncentiveElectric * SiteEnergySavings * 1,000,000/3,412	%IncentiveGas * SiteEnergySavings * 10
Gas utility only	N/A	SiteEnergySavings * 10

Where:

$BTU_{Surface}$[1916] = Annual heating energy load contributed by convection/radiation heat losses via pool surface

$$= \left(T_{pool} - T_{amb}\right) * A_{pool} * U * \left[hrs - \left(hrs_{cover} - ESF_{cover,surface}\right)\right]$$

BTU_{Reheat}[1917] = Annual heating energy load contributed by heating the full volume of pool water

$$= V_{pool} * 8.33 * \left(T_{pool} - T_{main}\right) * F_{Reheat}$$

BTU_{Evap}[1918] = Annual heating energy load contributed by evaporation

$$= 0.1 * AF * A_{pool} * \left(P_{\omega} - P_{dp}\right) * \left(T_{pool} - T_{main}\right) * \left[hrs - \left(hrs_{cover} * ESF_{cover,evap}\right)\right]$$

$F_{elec,baseline}$ = Baseline electric pool heater factor; used to account for the presence or absence of an electric pool heater.

= 1.0 if baseline system is electric resistance pool heater

= 0 if baseline system is not an electric resistance pool heater

$F_{fuel,baseline}$ = Baseline fossil fuel pool heater factor; used to account for the presence or absence of a fossil fuel-fired pool heater.

= 1.0 if baseline system is fossil fuel-fired pool heater

= 0 if baseline system is not a fossil fuel-fired pool heater

$COP_{baseline}$ = Coefficient of performance, ratio of output energy/input energy of baseline electric resistance pool heater, if present.

= 1.0 if heater is electric resistance; 3.5 if heater is a heat pump

COP_{ee} = Coefficient of performance, ratio of output energy/input energy of heat pump pool heater.

= Actual

$E_{t,baseline}$ = Thermal efficiency of baseline fossil fuel-fired pool heater, if present.

= 0.82 if unknown

T_{pool} = Pool temperature set point, (°F).

= Actual

T_{amb} = Average temperature of surrounding ambient air, (°F). If pool is indoors, this is the indoor temperature of room with pool from application. For outdoor pools, see "Ambient Air Temperature and Pressure (T_{amb} and P_{dp})" table below.

T_{main} = Supply water temperature in water main, (°F). See "Cold Water Inlet Temperature (T_{main})" table below.

A_{pool} = Surface area of pool, (ft^2). From application. Assistance in determining the area of common pool shapes as follows:[1919]

[1916] ASHRAE Handbook: HVAC Applications, 2019, Ch 51 Service Water Heating, Swimming Pools/Health Clubs.
[1917] Ibid, eqn. 14
[1918] ASHRAE Handbook: HVAC Applications, 2019, Ch 6 Indoor Swimming Pools, eqn. 3, multiplied by required heating temperature difference
[1919] Guidance for determining surface area of common pool shapes can be found at ASHRAE Handbook: HVAC Applications, 2019.

Elliptical: 3.14 x short radius x long radius

Kidney Shaped: 0.45 x length x (width at one end x width at other end)

Oval: 3.14 x radius^2 + (length of straight sides x width)

Rectangular: length x width

V_{pool} = Volume of pool water, (gallons)

= ActualFrom application.

F_{Reheat} = Factor capturing annual number of times full pool volume is heated to the desired temperature, whether as the result of refill or heating of pool water from ground water temperature at start of season. From application.

= 0 if pool is filled by delivery service providing preheated water

= 1 if otherwise[1920]

U = Surface heat loss coefficient, (BTU/hr ft^2 °F)[1921]

= 3.9 for indoor pool

= 5.3 for outdoor pool, sheltered

= 6.6 for outdoor pool, unsheltered

AF = Activity Factor, consideration of activity within pool, allowing for splashing and a limited area of wetted deck.[1922]

= 0.5

P_{ω} = Saturation vapor pressure taken at surface water temperature, (in. Hg). See "Saturation Vapor Pressure (P_{ω})" table below based on pool water temperature.

P_{dp} = Saturation pressure at dew point, (in. Hg). See "Ambient Air Temperature and Pressure (T_{amb} and P_{dp})" table below.

hrs = Total annual swimming season hours. From application. Hours shall reflect the total annual hours through the swimming season (number of days between season opening and season closing x 24).

hrs_{cover} = Total annual hours pool covered during the swimming season. From application. Hours shall reflect the total hours pool covered during the swimming season. Set equal to 0 if pool is left uncovered throughout swimming season.

$ESF_{cover,surface}$ = Energy Savings Factor of pool cover to insulate from convective and radiation heat losses

= 0.80[1923]

[1920] The water temperature of an undrained pool between swim seasons is assumed to have reached the water main temperature by the beginning of the next swim season. If the pool remains open throughout the year, it is assumed the pool undergoes one effective full pool volume reheat from water main temperature for cleaning and other maintenance (CDC, Healthy Swimming, Operating Public Swimming Pools).

[1921] ASHRAE Handbook: HVAC Applications, 2019, Ch 51, eqn. 15. Surface heat loss coefficient adjusted from ASHRAE Handbook rolled up surface heat transfer conservations by discounting contribution of evaporation (50-60%) and applying the following assumption for wind velocity: Indoor pools experience average wind speeds less than 3.5 mph (10.5x0.5x0.75), outdoor sheltered pools experience wind speeds between 3.5 and 5 mph (10.5x0.5), and outdoor unsheltered pools experience wind speeds above 5 mph (10.5x0.5x1.25).

[1922] ASHRAE Handbook, Applications, 2019, Ch 6, Table 1

[1923] U.S. D.O.E., Swimming Pool Covers.

$ESF_{cover,evap}$ = Energy Savings Factor of pool cover to insulate from evaporative heat loss

= 0.95[1924]

0.1 = Simplified empirically derived evaporation factor considering latent heat and air flow.[1925] Assumes 1,000 BTU/lb of latent heat required to change water to vapor at surface water temperature and air velocity over water surface ranging from 10 to 30 fpm, (lb/hr ft^2 in. hg)

8.33 = Energy required (BTU) to heat one gallon of water by one degree Fahrenheit

3,412 = Conversion factor, one kWh equals 3,412 BTU

Cold Water Inlet Temperature (T_{main})

Supply water main temperatures vary according to climate, and are approximately equal to the annual average outdoor temperature plus 6°F.[1926] Supply main temperatures based on the annual outdoor temperature are shown below.

Climate Zone	Annual Average Outdoor Temperature (°F)[1927]	T_{main} (°F)
1 (Rockford)	49.2	55.2
2 (Chicago)	51.4	57.4
3 (Springfield)	53.0	59.0
4 (Belleville)	57.3	63.3
5 (Marion)	56.5	62.5

Saturation Vapor Pressure (P_ω)

Lookup saturation vapor pressure taken at surface water temperature for indoor and outdoor pools from the table below, based on pool temperature.[1928]

Pool Temperature, T_{pool} (°F)	P_ω (in. Hg)
72	0.79
74	0.85
76	0.91
78	0.97
80	1.03
82	1.10
84	1.18

Ambient Air Temperature and Pressure (T_{amb} and P_{dp})

Indoor pools shall apply ambient air temperature from application based on facility set point temperature. Lookup

[1924] National Plasterers Council, Effectiveness of Pool Covers to Reduce Evaporation from Swimming Pools, prepared by California Polytechnic State University, January 2016.

[1925] Simplified constant presented in ASHRAE Handbook: HVAC Application 2019 Ch 6 based on empirically derived eqn (2) constants and ASHRAE's variable assumptions

[1928] ASHRAE Handbook: Fundamentals 2017, Ch 1 Psychrometrics, Table 3 Thermodynamic Properties of Water at Saturation

saturation vapor pressure based on facility set point temperature and relative humidity (RH) from the table below, based on psychrometric analysis. Interpolation may be performed for indoor pool ambient temperatures not listed.

Indoor Pool Temperature, T_{amb} (°F)	Indoor Pool, P_{dp} (in. Hg)		
	RH 50%	RH 55%	RH 60%
72	0.40	0.44	0.47
74	0.42	0.47	0.51
76	0.45	0.50	0.54
78	0.48	0.53	0.58
80	0.52	0.56	0.62
82	0.55	0.61	0.66
84	0.59	0.65	0.71
86	0.63	0.69	0.75

For outdoor pools, lookup T_{amb} and P_{dp} from the table below based on location. Ambient temperature averages for outdoor pools apply a 4-month swimming season.

Climate Zone	Outdoor Pool Temperature T_{amb} (°F)[1929]	Outdoor Pool P_{dp} (in. Hg)[1930]
1 (Rockford)	69.6	0.52
2 (Chicago)	73.4	0.53
3 (Springfield)	72.9	0.58
4 (Belleville)	73.9	0.60
5 (Marion)	74.8	0.62

Fuel Switch Example

A gas pool heater is replaced with a heat pump pool heater at a single family home located near Chicago. The swimming season spans 4 months (2,904 hours) per year and the pool is left uncovered at night. The pool is 15 ft by 30 ft and has a volume of 17,600 gallons, and is sheltered from winds by the house and backyard trees. The pool temperature is maintained at 80°F. The replaced gas pool heater has an efficiency of 82% and the heat pump pool heater has an efficiency of 5.0 COP. Annual Electric Energy Savings, Summer Peak Coincident Demand Savings and Annual Fossil Fuel Energy Savings are calculated as below.

$\Delta kWh = (BTUSurface + BTUReheat + BTUEvap)/3{,}412 \times (Felec,baseline/COPbaseline - 1/COPee)$

$\Delta kW = \Delta kWh/hrs \times CF$

$\Delta MMBtu = (BTUSurface + BTUReheat + BTUEvap)/1{,}000{,}000 \times Ffuel,baseline/Et,baseline$

where:

$BTUSurface = (Tpool - Tamb) \times Apool \times U \times [hrs - (hrscover \times ESFcover,surface)]$

$BTUReheat = Vpool \times 8.33 \times (Tpool - Tmain) \times FReheat$

[1929] DOE Weather Data, TMY3 (Typical Meteorological Year), developed by NREL. Adjusted to apply to outside air temperature from June 1 to September 30 in each climate zone.

[1930] DOE Weather Data, TMY3 (Typical Meteorological Year), developed by NREL. Saturation pressure at dew point calculated as a function of dew point and atmospheric pressure. Values averaged from June 1 to September 30 in each climate zone.

$BTUEvap$=0.1×AF×$Apool$×($P\omega$−Pdp)×($Tpool$−$Tmain$)×[hrs−($hrscover$×$ESFcover,evap$)]

Tpool = 80, from application

Tamb = 73.4, from Ambient Air Temperature and Pressure section based on location from application

Apool = width x length = 15’ x 30’ = 450 square feet

REVIEW DEADLINE: 1/1/2028

5.7.5 Tree Planting

DESCRIPTION

This measure describes savings from a program where utility sponsored staff work with homeowners or building operators to determine the appropriate location and ultimately plant trees to maximize HVAC savings.

How measure saves energy:

1. Trees when in full foliage block direct sunlight onto exterior surfaces of residences, and in the cooling season reduce energy use. Primary effects are reduced insulation into residences through windows. Secondary effects are reduced wall and roof temperatures which reduce conduction through walls and roofs into residences.
2. Trees when in full foliage block winds and associated infiltration into residences. This saves both heating and cooling energy since outdoor air is generally either hotter or colder than the desired indoor temperature.
3. Because trees have differential winter impacts, based on whether they are leaf-retaining (Coniferous) or leaf-shedding (Deciduous), there are significantly differential effects of tree types for each facing wall of a residence. Therefore, eligibility requirements for types of trees planted on specific residence wall faces have been set to maximize savings and minimize losses due to trees.
4. Trees must provide shading to at least the 3rd story of a home in the cooling season and eligibility therefore requires trees to be a minimum of 30 feet tall when fully mature.

Markets measure serves:

This measure provides benefits to single-family residences as well as multi-family residences. It provides benefits for all types of homes, from 1 story to 3 story residences. Trees must be planted within 30 feet of the walls of homes so that they provide shading during summer days when the sun is at a high angle.

Limitations to measure applicability:

This measure is inapplicable to residences that currently have trees shading the face where the trees are proposed to be added (that is, the face of the existing residence where the tree is proposed must currently be unshaded). Coniferous trees are ineligible on the East and South faces of residences because these trees block beneficial sunlight in the heating season, which reduces annual savings severely. Similarly, Deciduous trees are ineligible on North faces of residences because they lose their leaves in winter and therefore have a minimal wind-blocking effect on infiltration during prevailing NW and W winter winds; in addition, because they are on the North face, they provide attenuated benefits for summer cooling energy use.

This measure was developed to be applicable to the following program types: RF, NC. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Trees must be horticulturally defined as either leaf-retaining (e.g., Coniferous) or leaf-shedding (e.g., Deciduous). The eligibility of tree types are dependent on the orientation of the wall of the residence being shaded as follows:

1. On North-facing walls, only Coniferous trees (i.e., trees that retain leaves all year) are eligible.
2. On East- and South-facing walls, only Deciduous trees (i.e., trees that lose all leaves in Fall) are eligible.
3. On West-facing walls, both deciduous and coniferous trees are eligible.
4. Trees must be minimum 30 ft tall when fully mature and have a lifetime of at least 20 years in Midwest climate.
5. Trees must be planted within 30 feet of the wall that they are shading and no closer than 20 feet apart.

DEFINITION OF BASELINE EQUIPMENT

Residence wall where trees are proposed to be planted currently must be fully or partially unshaded OR currently be planted with “ineligible” trees that will be removed and replaced with “eligible” trees. If the residence wall

currently is partially shaded, the proposed tree must be planted in front of the currently unshaded portion of the wall.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

Savings from tree planting take a number of years to be realized as significant growth is required before the shading makes a significant impact. The length of time before savings are fully achieved will be dependent on a number of factors including size of tree when planted, proximity to building and the speed of growth. This measure has been designed based on the assumption that savings would not be achieved for the first five years and would then be realized from year 6 and for a further 20 years.

However, in order to simplify the implementation of this measure, a reduced savings is claimed from year 1 and for an assumed measure life of 25 years, which results in an equivalent present value of lifetime savings. This results in a 76% multiplier[1931] applied to the calculated annual savings for the measure.

If there is reason to believe that the length of time before savings are achieved is significantly different to the 5 years assumed, an alternative multiplier can be applied.

DEEMED MEASURE COST

Use actual installed cost per tree planted.

LOADSHAPE

Loadshape R08 - Residential Cooling

Loadshape R09 - Residential Electric Space Heat

Loadshape R10 - Residential Electric Heating and Cooling

COINCIDENCE FACTOR

The summer peak coincidence factor for cooling is provided in two different ways below. The first is used to estimate peak savings during the utility peak hour and is most indicative of actual peak benefits, and the second represents the *average* savings over the defined summer peak period, and is presented so that savings can be bid into PJM's capacity market.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during utility peak hour)

= 68%[1932]

CF_{SSP} = Summer System Peak Coincidence Factor for Heat Pumps (during system peak hour)

= 72%[1933]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during PJM peak period)

= 46.6%[1934]

[1931] Assuming Real Discount Rate of 2.0%.

[1932] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[1933] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[1934] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\text{Total } \Delta kWh = (\Delta kWh_{HeatingDirectSolar} + \Delta kWh_{CoolingDirectSolar} + \Delta kWh_{HeatingInfiltration} + \Delta kWh_{CoolingInfiltration}) * (1- LMR) * NPVDiscount$$

Where:

$\Delta kWh_{HeatingDirectSolar}$ = Annual heating savings due to reduction in Direct Solar Gain

= #Trees * ThermsHeatingIncrease/Tree * 100,000 / 3,412 / ηHeat * %ElectricHeat

#_Trees = total number of eligible trees planted
= actual number of eligible trees planted on any face of the residence

ThermsHeatingIncrease/Tree = net annual therms of heating increase per tree due to shading, based on the average annual savings of eligible trees planted on all faces of the residence

= - 3.2 Therms/tree [1935]

100,000 = conversion of Therms to BTUs

3,412 = conversion BTUs to kWh

ηHeat = Efficiency of heating system

= In order to account for the long-term aspect of this measure and the likely replacement of existing heating and cooling equipment during the lifetime of this measure, the following system efficiency assumptions should be used:

Efficiency Assumption	System Type	New Baseline Efficiency
ηHeat	Electric Resistance (Baseboard or Electric Furnace)	1.0 COP
	Heat Pump (7.0HSPF2/3.412)*0.85	1.74 COP
	Furnace 80% AFUE * 0.85	68% AFUE
	Boiler	84% AFUE

%ElectricHeat = Percent of homes that have electric space heating

= 100 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= 0 % for Natural Gas

[1935] Savings are based upon a modeling spreadsheet provided by Leidos – see 'Shade Tree Energy Savings – REVISED.xlsx'. This analysis includes a large number of assumptions and therefore resultant savings were trued up against TRM assumptions of full cooling energy consumption to result in a percentage savings that was consistent with a number of reviewed studies (namely: Home Energy Magazine: "Shade Trees as a Demand-Side Resource", Energy and Buildings: "Peak power and cooling energy savings of shade trees", and Ecological Economics: "Energy Savings from tree shade". These references can be found in the reference folder.)

= If unknown[1936], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	14.0%	13.7%	37.2%	56.3%	19.5%
ComEd	14.0%	21.5%	43.0%	48.4%	32.9%
PGL	1.0%	1.5%	4.0%	2.8%	2.2%
NSG	1.3%	0.8%	32.5%	1.2%	3.3%
Nicor	1.6%	3.8%	13.5%	21.6%	4.7%
All DUs[1937]					24.6%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

$\Delta kWh_{CoolingDirectSolar}$ = Annual cooling savings due to reduction in Direct Solar Gain

= #Trees * Ton-hrCoolingSaved/Tree * LoadFactor * 12,000 / (1,000 * ηCool) * %Cool

Ton-hrCoolingSaved/Tree = Net annual Ton-hours of cooling saved per tree due to shading, based on the average annual savings of eligible trees planted on all faces of the residence

= 137.3 ton-hrs/year/tree[1938]

LoadFactor = Factor to reflect expected relative load (and therefore savings) or homes with Room AC v Central AC.

= 1.0 for homes with central AC, 0.41 for homes with Room AC[1939]

12,000 = conversion of ton-hours to BTUs

ηCool = Efficiency (SEER2 or CEER) of Air Conditioning equipment (kBtu/kWh) * Distribution Efficiency

= In order to account for the long-term aspect of this measure and the likely replacement of existing heating and cooling equipment during the lifetime of this measure, the following system efficiency assumptions should be used:

[1936] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1937] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore electric only homes. Ameren is total customers minus Nicor.

[1938] Savings are based upon a modeling spreadsheet provided by Leidos – see 'Shade Tree Energy Savings – REVISED.xlsx'. This analysis includes a large number of assumptions and therefore resultant savings were trued up against TRM assumptions of full cooling energy consumption to result in a percentage savings that was consistent with a number of reviewed studies (namely: Home Energy Magazine: "Shade Trees as a Demand-Side Resource", Energy and Buildings: "Peak power and cooling energy savings of shade trees", and Ecological Economics: "Energy Savings from tree shade". These references can be found in the reference folder.)

[1939] Based upon review of 102 room AC replacement projects completed in 2023 and 2024 for an Illinois multifamily energy efficiency program, the average room AC capacity installed was 11.41 MBh per living unit. From Section 5.3.3 for Central Air Conditioning, default central A/C capacity is 28 MBh. This results in a capacity scale factor of 11.41 / 28 = 0.41 when using room air conditioner cooling.

System Type	SEER2/CEER Estimate	ηCool (SEER2 * 0.85)
Central AC	12.4	10.5
Heat Pump	13.3	11.3
Room AC[1940]	10.9	10.9
Unknown (for use in program evaluation only)[1941]		
Single Family Non-IQ		10.6
Single Family IQ		10.6
Multi Family Non-IQ		10.3
Multi Family IQ		10.4
Unknown		10.5

%Cool = Percent of homes that have cooling

Cooling (Central or Room AC)	%Cool (By Market Segment)				
	Single Family Non-IQ	Single Family IQ	Multi Family Non-IQ	Multi Family IQ	Unknown
Yes	100%				
No	0%				
Unknown (for use in program evaluation only)[1942]	98.9%	96.5%	99.8%	98.7%	98.6%

$\Delta kWh_{HeatingInfiltration}$ = Annual heating savings due to reduction in infiltration

= #Trees * CFM50/sqft * Area/ N_Heat * %Reduction_HeatingInfiltration/Tree * 60 * 24 * HDD60 * 0.018 / (COPHeating * 3,412) * %ElectricHeat

CFM50/sqft = Average CFM of infiltration per square foot of residence floor area based on 50 pascal pressure differential (This is a Customer Input of degree of leakage rate of house; Assumes the CFM50 leakage rates in the following table; assumes CFM50 leakage rates were based on a typical 2,250 sq. ft. residence.)

Shade Tree ECM Constants	CFM50/sqft	CFM50	Source
Leaky/Low Insulation	2.22	5,000 CFM at 50 pascal	Estimate for Leaky 2,250 sqft dwelling
Average/Average Insulation Or if Unknown	1.51	3,400 CFM at 50 pascal	Estimate for Average 2,250 sqft dwelling
Tight/High Insulation	1.00	2,250 CFM at 50 pascal	Estimate for Tight 2,250 sqft dwelling

Area = floor area of residence

= actual

%Reduction_HeatingInfiltration/Tree = Average infiltration reduction per tree during heating season due to tree blocking wind, based on average annual savings of eligible trees planted on all faces of the residence.

[1940] For non-IQ participants, this is based on the minimum Federal Standard for the most common room AC type (8000-13,999 capacity range without reverse cycle and with louvered sides) from 6/1/2014 to 5/26/2026 and for IQ participants the Federal Standard for the same unit type prior to 6/1/2014 (9.8EER is converted to 9.7CEER by dividing by 1.01).

[1941] Efficiencies presented above are weighted as per data provided by GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

[1942] Based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024.

= 0.47% infiltration reduction per tree [1943]

N_heat = Conversion factor from leakage at 50 Pascal to leakage at natural conditions

= Based on climate zone, building height and exposure level:[1944]

Climate Zone (City based upon)	N_heat (by # of stories)			
	1	1.5	2	3
1 (Rockford)	23.8	21.1	19.3	17.1
2 (Chicago)	23.9	21.1	19.4	17.2
3 (Springfield)	24.2	21.5	19.7	17.4
4 (St Louis, MO)	25.4	22.5	20.7	18.3
5 (Paducah, KY)	27.8	24.6	22.6	20.0

60 = conversion of ton-hours cooling to BTUs

24 = conversion of Watts to kWh

HDD = Heating Degree Days

= Dependent on location:[1945]

Climate Zone (City based upon)	HDD 60
1 (Rockford)	5230
2 (Chicago)	4798
3 (Springfield)	4266
4 (Belleville)	3188
5 (Marion)	3390
Weighted Average[1946]	4631

0.018 = Specific Heat capacity of Air (BTU/Cu.Ft./F)

$\Delta kWh_{CoolingInfiltration}$ = Annual cooling savings due to reduction in infiltration

= #Trees * CFM50/sqft * Area / N_Cool * %_ ReductionCoolingInfiltration/Tree * 60 * 24 * CDD65 * LM * 0.018 / (ηCool * 1000) * %Cool

[1943] Savings are based upon a modeling spreadsheet provided by Leidos – see 'Shade Tree Energy Savings – REVISED.xlsx'. This analysis includes a large number of assumptions and therefore resultant savings were trued up against TRM assumptions of full cooling energy consumption to result in a percentage savings that was consistent with a number of reviewed studies (namely: Home Energy Magazine: "Shade Trees as a Demand-Side Resource", Energy and Buildings: "Peak power and cooling energy savings of shade trees", and Ecological Economics: "Energy Savings from tree shade". These references can be found in the reference folder.)

[1944] N-factor is used to convert 50-pascal blower door air flows to natural air flows and is dependent on geographic location and # of stories. These were developed by applying the LBNL infiltration model (see LBNL paper 21040, *Exegisis of Proposed ASHRAE Standard 119: Air Leakage Performance for Detached Single-Family Residential Buildings*; Sherman, 1986; page v-vi, Appendix page 7-9) to the reported wind speeds and outdoor temperatures provided by the NRDC 30 year climate normals. For more information see Bruce Harley, CLEAResult "Infiltration Factor Calculations Methodology.doc".

[1945] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 60°F, consistent with the findings of Belzer and Cort, Pacific Northwest National Laboratory in "Statistical Analysis of Historical State-Level Residential Energy Consumption Trends," 2004. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[1946] Weighted based on number of occupied residential housing units in each zone.

N_cool = Conversion factor from leakage at 50 Pascal to leakage at natural conditions

=Dependent on location and number of stories:[1947]

Climate Zone (City based upon)	N_cool (by # of stories)			
	1	1.5	2	3
1 (Rockford)	39.5	35.0	32.1	28.4
2 (Chicago)	38.9	34.4	31.6	28.0
3 (Springfield)	41.2	36.5	33.4	29.6
4 (St Louis, MO)	40.4	35.8	32.9	29.1
5 (Paducah, KY)	43.6	38.6	35.4	31.3

%Reduction_CoolingInfiltration/Tree = Average infiltration reduction per tree during cooling season due to tree blocking wind, based on average annual savings of eligible trees planted on all faces of the residence.

= 2.26% infiltration reduction per tree [1948]

CDD = Cooling Degree Days

= Dependent on location:[1949]

Climate Zone (City based upon)	CDD 65
1 (Rockford)	877
2 (Chicago)	1047
3 (Springfield)	1183
4 (Belleville)	1641
5 (Marion)	1450
Weighted Average[1950]	1098

LM = Latent Multiplier

= Multiplies the CDD dry bulb temperature difference by a factor that accounts for the additional energy needed to dehumidify air when in cooling mode

Climate Zone (City based upon)	LM
1 (Rockford)	3.3
2 (Chicago)	3.2

[1947] N-factor is used to convert 50-pascal blower door air flows to natural air flows and is dependent on geographic location and # of stories. These were developed by applying the LBNL infiltration model (see LBNL paper 21040, *Exegisis of Proposed ASHRAE Standard 119: Air Leakage Performance for Detached Single-Family Residential Buildings*; Sherman, 1986; page v-vi, Appendix page 7-9) to the reported wind speeds and outdoor temperatures provided by the NRDC 30 year climate normals. For more information see Bruce Harley, CLEAResult "Infiltration Factor Calculations Methodology.doc".

[1948] Savings are based upon a modeling spreadsheet provided by Leidos – see 'Shade Tree Energy Savings – REVISED.xlsx'. This analysis includes a large number of assumptions and therefore resultant savings were trued up against TRM assumptions of full cooling energy consumption to result in a percentage savings that was consistent with a number of reviewed studies (namely: Home Energy Magazine: "Shade Trees as a Demand-Side Resource", Energy and Buildings: "Peak power and cooling energy savings of shade trees", and Ecological Economics: "Energy Savings from tree shade". These references can be found in the reference folder.)

[1949] National Centers for Environmental Information (NCEI) Annual Normals, from 2006 - 2020, calculated with a base temp of 65°F. There is a county mapping table Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois.

[1950] Weighted based on number of occupied residential housing units in each zone (US Census 2010).

Climate Zone (City based upon)	LM
3 (Springfield)	3.7
4 (St Louis, MO)	3.6
5 (Paducah, KY)	3.7

LMR = Lifetime Mortality Rate – i.e. assumed percentage of trees that do not go on to provide the savings characterized in this measure.

= 18% for single family and 39% for multi family[1951]

NPVDiscount = Multiplier to reduce annual savings claimed from year 1 to account for assumed length of time before savings are realized.

= 76%[1952]

[1951] Assumption based on McPherson, "Energy-Saving Potential of Trees in Chicago", page 24.

[1952] Based on assumption that savings would not be realized for first 5 years and then continue for 20 years. Applying this multiplier and claiming savings from year one and for a measure life of 25 years results in equivalent NPV of lifetime savings, applying a Real Discount Rate of 2.0%. If reason to believe savings will be realized after a significantly different length of time, and alternative multiplier can be calculated.

For example: Assuming 5 eligible trees are planted around home with average leakage and Insulation Levels; 2,500 Sq. Ft. floor area in a 2 story Single Family Residence in Springfield with an Air Source Heat Pump with unknown efficiency.

$$\Delta kWh = (\Delta kWh_{HeatingDirectSolar} + \Delta kWh_{CoolingDirectSolar} + \Delta kWh_{HeatingInfiltration} + \Delta kWh_{CoolingInfiltration}) * (1 - LMR) * NPVDiscount$$

$\Delta kWh_{HeatingDirectSolar}$ = #Trees * ThermsHeatingIncreased/Tree * 100,000 / 3,412 / ηHeat * %ElectricHeat

= 5 * -3.2 * 100,000 / 3,412 / 2.04 * 100%

= -230 kWh

$\Delta kWh_{CoolingDirectSolar}$ = #Trees * Ton-hrCoolingSaved/Tree * 12,000 / (1,000 * ηCool) * %Cool

= 5 * 137.3 * 12,000 / (1,000 * 14) * 100%

= 588 kWh

$\Delta kWh_{HeatingInfiltration}$ = #Trees * CFM50/sqft * Area/ N_Heat * %Reduction_HeatingInfiltration/Tree * 60 * 24 * HDD60 * 0.018 / (COPHeating * 3,412) * %ElectricHeat

= 5 * 1.51 * 2,500/19.7 * 0.47% * 60 * 24 * 4,266 * 0.018 / (2.04 * 3,412) * 100%

= 72 kWh

$\Delta kWh_{CoolingInfiltration}$ = #Trees * CFM50/sqft * Area / N_Cool * %_ ReductionCoolingInfiltration/Tree * 60 * 24 * CDD65 * LM * 0.018 / (ηCool * 1000) * %Cool

= 5 * 1.51 * 2,500/33.4 * 2.26% * 60 * 24 * 1,183 * 3.7 * 0.018 / (14 * 1,000) * 100%

= 104 kWh

ΔkWh = (-230 + 588 + 72 + 104) * (1 – 0.18) * 0.76

= 333 kWh (67 kWh per tree)

SUMMER COINCIDENT PEAK DEMAND SAVINGS

$$\Delta kW = kWh_{Cool} / FLH_Cooling * CF * (1\text{-}LMR) * NPVDiscount$$

Where:

kWh_{Cool} = Total cooling kWh savings from measure

= $\Delta kWh_{CoolingDirectSolar} + \Delta kWh_{CoolingInfiltration}$

FLH_cooling = Full load hours of air conditioning

= Dependent on location:[1953]

[1953] Full load hours for Chicago, Moline and Rockford are provided in "Final Evaluation Report: Central Air Conditioning Efficiency Services (CACES), 2010, Navigant Consulting", p.33. An average FLH/Cooling Degree Day (from NCDC) ratio was calculated for these locations and applied to the CDD of the other locations in order to estimate FLH. There is a county mapping table in Volume 1, Section 3.7 providing the appropriate city to use for each county of Illinois. During update cycle for version

Climate Zone (City based upon)	Single Family	Multifamily
1 (Rockford)	547	499
2 (Chicago)	709	629
3 (Springfield)	779	707
4 (Belleville)	1082	982
5 (Marion)	956	868
Weighted Average[1954]		
ComEd	676	603
Ameren	875	791
Statewide	731	655

Use Multifamily if: Building meets utility's definition for multifamily and HVAC system serves single unit. For residential sized systems serving 2 or more units, assume single family hours.

CF_{SSP} = Summer System Peak Coincidence Factor for Central A/C (during system peak hour)

= 68%[1955]

CF_{SSP} = Summer System Peak Coincidence Factor for Heat Pumps (during system peak hour)

= 72% [1956]

CF_{PJM} = PJM Summer Peak Coincidence Factor for Central A/C (average during peak period)

= 46.6% [1957]

For example, using example from above and CF_{SSP} for heat pumps:

$\Delta kW = kWh_{Cool} / FLH_Cooling * CF * (1 - LMR) * NPVDiscount$

$kWh_{Cool} = 588 + 104$

$= 692$

$\Delta kW = 692 / 711 * 0.72 * (1-0.18) * 0.76$

$= 0.437$

FOSSIL FUEL SAVINGS

$$\Delta Therms = (\Delta Therms_{HeatingDirectSolar} + \Delta Therms_{HeatingInfiltration}) * (1- LMR) * NPVDiscount$$

Where:

$\Delta Therms_{HeatingDirectSolar}$ = Annual therm savings due to reduction in direct solar gain

= #_Trees * ThermsHeatingIncreased/Tree / ηHeat * %FossilHeat

v.12, applied percent change of CDD65, NCEI Annual Normals from 30 yr data set (1981-2010) to more recent 15 yr data (2006-2020) to all FLHcool values.

[1954] Weighting for Ameren is based on electric accounts in each of the cooling zones. Weighting for ComEd and Statewide average is based on number of occupied residential housing units in each zone. ComEd is weighted average of Zones 1-2. Alternative program-weighted assumptions can be used if appropriate.

[1955] Based on metering of 24 homes with central AC during PY4 and PY5 in Ameren Illinois service territory.

[1956] Based on analysis of metering results from 24 heat pumps in Ameren Illinois service territory in PY5 coincident with AIC's 2010 system peak; 'Impact and Process Evaluation of Ameren Illinois Company's Residential HVAC Program (PY5)'.

[1957] Based on analysis of Itron eShape data for Missouri, calibrated to Illinois loads, supplied by Ameren. The average AC load over the PJM peak period (1-5pm, M-F, June through August) is divided by the maximum AC load during the year.

ThermsHeatingIncreased/Tree = Net annual therms of heating saved per tree due to shading and infiltration effects, based on the average annual savings of eligible trees planted on all faces of the residence.

= -3.2 Therms/Tree

ηHeat = as defined above

%FossilHeat = Percent of homes that have fossil fuel space heating

= 100 % for Fossil fuel

= 0 % for Electric Resistance (Baseboard or Electric Furnace) or Heat Pump

= If unknown[1958], use the following table:

Utility	Location				
	Single Family	Single Family Low Income	Multi Family	Multi Family Low Income	Unknown
Ameren	86.0%	86.3%	62.8%	43.7%	80.5%
ComEd	86.0%	78.5%	57.0%	51.6%	67.1%
PGL	99.0%	98.5%	96.0%	97.2%	97.8%
NSG	98.7%	99.2%	67.5%	98.8%	96.7%
Nicor	98.4%	96.2%	86.5%	78.4%	95.3%
All DUs[1959]					75.4%

Note: If a measure is supported by a gas and electric utility through a joint program, and it is unknown whether the participant has a gas supply, the electric utility values in the table above should be used. If it is known that the participant has a gas supply, the values from the gas utility above should be applied.

$\Delta Therms_{HeatingInfiltration}$ = Annual therm savings due to reduction in infiltration

= #Trees * CFM50/SqFt * Area/ N_Heat * %_ ReductionHeatingInfiltration/Tree * 60 * 24 * HDD60 * 0.018 / (ηHeat * 100,000)

[1958] Ameren and Nicor values are based on GDS Associates Inc., "2023-2024 Illinois Baseline Study: Residential Baseline Study Results", Oct 31 2024. ComEd values based on 2019 Baseline Survey and People's Gas and Northshore Gas values are based on implementation contractors data for PY2022-2023.

[1959] For the weighted average calculations, please see the Analysis file. PGL, NSG, Nicor & gas customers were assumed to follow the provided split. ComEd total customers, minus overlap with PGL,NSG & Nicor, therefore gas only homes. Ameren is total customers minus Nicor.

For example: Assuming 5 eligible trees are planted around home with average leakage and Insulation Levels; 2,500 Sq. Ft. floor area in a 2 story Single Family Residence in Springfield with furnace with system efficiency of 68%.

$$\Delta Therms = (\Delta Therms_{HeatingDirectSolar} + \Delta Therms_{HeatingInfiltration}) * (1 - LMR) * NPVDiscount$$

$\Delta Therms_{HeatingDirectSolar}$ = #Trees * ThermsHeatingIncreased/Tree / ηHeat * %FossilHeat

= 5 * -3.2/0.68 * 100%

= -23.5 Therms

$\Delta Therms_{HeatingInfiltration}$ = #Trees * CFM50/SqFt * Area/ N_Heat * %_ ReductionHeatingInfiltration/Tree * 60 * 24 * HDD60 * 0.018 / (ηHeat * 100,000)

= 5 * 1.51 * 2,500/19.7 * 0.47% * 60 * 24 * 4,266 * 0.018 / (0.68 * 100,000) * 100%

= 7.3 Therms

$\Delta Therms$ = (-23.5 + 7.3) * (1 – 0.18) * 0.76

= - 10.1 Therms

5.7.6 Smart Irrigation Controls

DESCRIPTION

Irrigation systems are commonly found on commercial properties, educational institutions, public parks, golf courses, and other facilities with landscaped grounds. They are typically operated on timers, applying the irrigation water in the early morning or after dusk. The timing and duration of irrigation application are determined by the user, along with the location and density of sprinklers. The irrigation water gets applied according to the control schedule, regardless of whether the landscape actually needs the irrigation water at that time.

The new measure involves the installation of a control system technology that reduces or eliminates irrigation during times of precipitation or when there is already sufficient soil moisture.

This measure applies to landscape irrigation systems for residential properties only. This measure was developed to be applicable to the following program types: TOS, RF. If applied to other program types, the measure savings should be verified.

DEFINITION OF EFFICIENT EQUIPMENT

Smart Irrigation Controls utilize sensors, gauges, or local weather forecasts to regulate the application of irrigation water to lawn or landscape vegetation. There are two main technologies used for this purpose: 1) Precipitation based smart irrigation controllers, and 2) Soil-moisture based smart irrigation controllers. Precipitation Based Smart Irrigation Controllers This type of system utilizes either an on-site rain gauge or a local weather service to determine if there is sufficient precipitation to allow shut-off of the irrigation water. Soil Moisture Based Smart Irrigation Controllers This type of system utilizes soil moisture sensors, buried in the root zone, to determine if irrigation water is needed. A “suspended cycle irrigation system” uses the soil moisture sensors to determine whether a regularly scheduled irrigation application is necessary. If there is sufficient soil moisture, then the next scheduled irrigation cycle gets interrupted. A “water-on-demand irrigation system” applies irrigation water when the moisture sensor reaches its lower limit and shuts off when the moisture sensor reaches its upper limit. There is no regularly scheduled irrigation with the water on demand system. For the purposes of this measure characterization, the assumed rolling 24-hour threshold for shutting off the irrigation is 6 mm (0.24”). The Savings Factor is based on the percentage of time that the rolling 24-hour average of precipitation meets or exceed the 6 mm threshold.

DEFINITION OF BASELINE EQUIPMENT

The baseline irrigation system applies irrigation water to the lawn or landscape on a regularly scheduled timer. The timing and duration of irrigation application are determined by the user, along with the location and density of sprinklers. The irrigation water gets applied according to the control schedule, regardless of whether the landscape actually needs the irrigation water at that time. Sprinkler head nozzles have a variety of configurations that affect the distribution of the irrigation water. The water can come in the form of a spray, a rotating plume, a bubbler, or a drip. Typical baseline irrigation systems provide 1 inch of irrigation to the entire lawn. This is equivalent to 0.623 gallons per square foot of lawn per week.[1960]

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

The expected useful life for Irrigation Control Measures is assumed to be 15 years.

DEEMED MEASURE COST

The measure cost for a multi-zone smart irrigation control system is $500.[1961]

[1960] Today’s Homeowner with Danny Lipford. “How to Calculate Lawn Irrigation Water Usage and Costs.”

[1961] Material pricing taken from Google shopping search on “smart irrigation control system”. The Rain Bird Smart LNK WiFi Irrigation System Indoor Controller (4 Pack) sells for $316 from online retailer Wish.com. Installation labor pricing taken from online retailer Home Advisor – Lawn and Garden, Repair a Sprinkler, which stated $45 to $200 per hour for a plumber.

CALCULATION OF ENERGY SAVINGS

Energy savings from Irrigation Control Measures are the result of reduced water consumption. There are indirect electric energy savings from reduced potable water treatment.

ELECTRIC ENERGY SAVINGS

The electric energy savings are based indirectly on the reduced electricity usage used to provide the potable water and treat the wastewater. By applying an "Energy Factor", the water savings (in gallons/year) can be converted to electricity savings (in kWh/year). This "Energy Factor" considers the electric energy requirements of potable water treatment plants and potable water distribution. Since the "wasted" irrigation water in the baseline case will likely be absorbed into the soil or will runoff into surface water bodies, electricity savings from a reduction in wastewater treatment load would not apply. The methodology for quantifying the water savings involves a direct comparison of the baseline equipment to the efficient equipment. In order to calculate the baseline water usage of an irrigation system, the number of sprinklers and their sizing need to be determined. The static pressure and sizing of the water service, along with the sprinkler head orifice sizing will ultimately determine the flow rate of water. The electricity savings for this measure can be calculated by applying an energy factor to the calculated water savings.

$$\Delta kWhwater = \frac{\Delta Water}{1{,}000{,}000} * Ewater$$

Where:

Ewater = Illinois Total Water Energy Factor (kWh/Million Gallons)

=2,571[1962]

The total water savings for this measure can be calculated as follows:

$$\Delta Water = BSFL - ESFL$$

Where:

ΔWater = Total Water Savings (gallon/season)

The baseline volumetric flow rate for the entire system can be calculated as follows:

$$BSFL = NOS * SFL * DOI * NAY$$

Where:

BSFL = Baseline System Flow Rate (gallon/year)

NOS = Number of Sprinklers, the total number of sprinklers at the property

= Actual SFL = Sprinkler Flow Rate (gallon/minute)

= Actual, site-specific irrigation system specifications should be consulted to determine

[1962] This factor include 2571 kWh/MG for water supply based on Illinois energy intensity data from a 2012 ISAWWA study and 2439 kWh/MG for wastewater treatment based on national energy intensity use estimates. For more information please review Elevate Energy's 'IL TRM: Energy per Gallon Factor, May 2018 paper'.

the property's sprinkler flow rate

DOI = Duration of Irrigation (minutes/application)

= Actual, the baseline scheduling controls should be used to determine the irrigation season

NAY = Number of Applications per Year (application/year)

= Actual

The efficient volumetric flow rate can be calculated as follows:

$$ESFL = BSFL * (1 - SF)$$

Where:

ESFL = Efficient System Flow Rate (gallon/season)

BSFL = Baseline System Flow Rate (gallon/season)

SF = Savings Factor

The volumetric flow rate for the entire efficient system is based on applying a Savings Factor (SF) to the BSFL. The SF is determined by calculating the number of weeks in the irrigation season (April 25 through October 13) when there is sufficient precipitation to allow the shutoff of the irrigation system. Typical Meteorological Year (TMY-3) data gives precipitation depth in millimeters for each hour of the typical year. By consulting the TMY-3 data for the closest applicable weather station, the SF can be determined.

One source recommends a rain sensor shut-off threshold of 6 mm of precipitation for twice or thrice weekly irrigation schedule or 13 mm of precipitation for once weekly irrigation schedule.[1963]

The State Climatologist Office for Illinois produced a map of the Illinois Growing Season days per year for different parts of the state.[1964]

By analyzing the TMY-3 precipitation data, the number of weeks during the "irrigation season" that the rolling 24-hour precipitation levels greater than 6 mm can be determined, along with the Savings Factors:

Chicago: SF= 0.265

Midway: SF = 0.241

Rockford: SF = 0.268

Peoria: SF = 0.227

Springfield: SF = 0.186

[1963] Michael D. Dukes. "Smart Irrigation Controllers: What Makes an Irrigation Controller Smart". University of Florida, Institute for Food & Agricultural Sciences.

[1964] State Climatologist Office for Illinois, Illinois State Water Survey, 2003. Based on 1971 – 2000 data, assessing the number of days between the last spring drop below 32 degrees and the firest fall drop below 32 degrees.

For example, an irrigation system in Rockford with 10 sprinklers running at 5 gallons per minute, 20 minutes per sprinkle with 100 sprinkles per year would save:

ΔkWh = ΔWater / 1,000,000 * Ewater

ΔWater = BSFL – ESFL

BSFL = NOS * SFL * DOI * NAY

= 10 * 5 * 20 * 100

= 100,000

ESFL = BSFL * (1 – SF)

= 100,000 * (1 – 0.268)

= 73,200

ΔWater = 100,000 – 73,200

= 26,800

ΔkWh = 26,800 / 1,000,000 * 2571

= 68.9 kWh

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

The water savings inherent in the efficient irrigation control technology will help preserve water supplies and extend the life of water treatment and wastewater treatment equipment. By reducing irrigation during periods of precipitation, unnecessary storm runoff and puddling can be avoided. For more details on calculating water savings, please see the 'Algorithm' section of this characterization.

DEEMED O&M COST ADJUSTMENT CALCULATION

Maintaining an Efficient Irrigation Control system will require periodic cleaning and calibration of the sensors. Any wiring or wireless communication devices will also need to be maintained. Costs for these activities is $196.[1965]

6 Cross-Cutting Measures

6.1 Behavior

6.1.1 Adjustments to Behavior Savings to Account for Persistence

DESCRIPTION

Energy efficiency program administrators are increasingly including behavior programs as part of their portfolios. These programs are characterized by various kinds of outreach, education, and customer engagement designed to motivate increases in conservation and energy management behaviors, and most commonly include participant specific energy usage information. Savings impacts are evaluated by ex-post billing analysis comparing consumption before and after (or with and without) program intervention, and require M&V methods that include customer specific energy usage regression analysis and randomized controlled trial (RCT) experimental designs, among others (see Behavioral protocol set forth in the IL-TRM Attachment A: Illinois Statewide Net-to-Gross Methodologies for more information). As such, initial calculation of savings is treated as a custom protocol.[1]

An important issue for many stakeholders is whether energy savings from behavior programs continue over time (i.e., whether they persist beyond the initial program year). Behavior programs have now been delivered for a number of years in many jurisdictions. The weight of evaluation evidence indicates that the energy-saving behaviors influenced through at least some types of these programs can persist beyond the initial period of program intervention, even without continued program participation.[2] This post-treatment savings persistence has implications for calculations of first-year savings, measure life, and cost-effectiveness testing. Accounting for persistence will yield savings and cost-effectiveness estimates that more accurately reflect the true benefits of these programs. Because annual goals are based on first-year savings, programs should count, and only count, savings attributable to first-year spending. The effect of persistence of savings from such spending beyond the first year should be included in any lifetime savings calculations (including cumulative persistent annual savings) and cost effectiveness testing.

The protocol below was developed to outline the adjustments that should be made to account for the persistence of savings beyond the year of program delivery. This general protocol is applicable to behavior programs of any type, delivered to residential or C&I customers, that have evaluated evidence of program persistence. However, the deemed persistence values and measure life in this version of the protocol are specific to residential home energy reports (HERs)-type programs only.[3] Evaluations in Illinois and elsewhere have shown that at least some of the savings from residential HERs-type behavior programs can persist into the first several years following discontinuation of program delivery, though on-going savings levels decay over time.[4] For residential RCT programs evaluated to date, savings have been shown to persist for at least two years and as much as eight years following program delivery,[5] and industry expectations are that savings may persist beyond that. For any other program type,

[1] The protocol outlined here assumes that adjustments to remove the effects of savings from program lift (participation in other utility programs), including legacy uplift, to account for move-outs and opt-outs, to normalize for effects of weather, and any other appropriate adjustments, have been made as part of the custom calculation of savings – this final savings value is referred to as "Measured Savings" in the calculations below.

[2] Long-Run Savings and Cost-Effectiveness of Home Energy Reports Programs, Cadmus, October 2014. Also see additional sources in the REFERENCE TABLES section below.

[3] Residential HERs-type programs: programs that regularly deliver home energy reports to residential customers through direct mail or email channels using a random control trial (RCT) experimental design. At a minimum, the reports include customer specific usage information used for a comparison to similar households and individualized energy savings tips.

[4] See REFERENCE TABLES below for sources.

[5] Long-Run Savings and Cost-Effectiveness of Home Energy Reports Programs, Cadmus, October 2014. Also see additional sources in the REFERENCE TABLE below. Given the variable characteristics of persistence studies available, we acknowledge that using an average of these studies by fuel type may be the best approximation of persistence rates. However, moving forward, the TAC will incorporate additional study values and develop the most appropriate persistence factors, taking into account when possible participant characteristics, such as the duration of exposure, the frequency of reports, baseline usage, as well as the amount of time that has persisted since receiving their final report, and the shape of the persistence curve.

persistence factors and years of persistence will only be deemed for application once supportable assumptions for persistence exist as measured by multi-year, rigorous evaluation studies.

Evaluations of residential HERs-type programs calculate a custom value on an annual basis to estimate yearly savings which is the initial input value for application of this persistence protocol. Evaluators typically use a regression analysis to estimate program effects. These regression analyses provide what is called an average treatment effect (ATE) estimate of program savings. The ATE approach takes advantage of the presence of a randomly assigned control group for each cohort that received reports in the service territory. These regressions use various methods to account for household-specific usage patterns.[6] Because of the experimental design, we can assume that the treatment and control groups experienced similar historical, political, economic, and other events that had comparable effects on their energy use. Moreover, because these groups experienced generally similar weather conditions, it is not necessary to measure or include weather in the RCT model specification to calculate initial annual savings related to the program.

However, in the case of comparing and summing savings year over year, exogenous factors, such as weather, are likely to make annual estimates non-equivalent. In particular, weather is likely to play an important role in driving behavioral effects, affecting savings magnitude (e.g., a constant percentage change in consumption will result in more cooling savings during a hotter-than-average summer), as well as savings rate (e.g., the percentage change in consumption is likely to be higher during hotter-than-average summers. As such, for this framework, evaluators will adjust for effects related to weather as part of the custom inputs to this protocol. Each evaluator will choose the most appropriate method for weather normalization. For example, one method would be to provide savings using a model specification that incorporates standard weather year inputs (e.g., HDD and CDD), to be used as the initial input into the calculation of annual savings, as well as inputs for cost effectiveness, as outlined below. This input will approximate average savings for a standard weather year based upon historical data.[7] Adjusting savings to a standard weather year is consistent with how other weather-sensitive TRM measures are specified, and will remove weather risk from performance goals and cost-effectiveness testing.[8]

For any new programs (referred to as “waves” in the calculations below), their first year will be assumed to be Year 1 for that wave – that is, each wave is tracked separately, and savings are calculated separately using the approach outlined here. The assumptions and protocols outlined below will not be applied retrospectively to any utility programs.

Updates to persistence factors and prospective retention rates from future evaluations, once incorporated into the IL-TRM, will be used when available for calculation of annual savings values for applicable program years but will not be applied retrospectively to previous years’ savings calculations. This includes that when persistence factors and retention rates are changed, the evaluation will utilize the persistence factors and retention rates that were used to calculate claimed savings in previous years to subtract persistence savings from those years. For example, persistence factors changed between CY2021 and CY2022; in CY2021 the earlier persistence factors (based on a 5-year measure life) were used to claim savings from CY2021- CY2025, therefore in CY2022-CY2025 persisting savings from CY2021 should be subtracted based on those same persistence factors. Savings for CY2022 and forward would use the new persistence factors. The same logic applies for prospective retention rates. This avoids a situation where savings that have never been claimed are being subtracted as persisting (for example, avoiding the situation where in CY2018 the utility only got to claim 15% of savings for CY2022, but now in CY2022 we are going to subtract 37% of savings as persistence from CY2018).

[6] For example, a linear fixed-effects regression (LFER) model includes a household-specific intercept to account for time invariant, household-level factors affecting energy use, and a post program regression (PPR) model uses energy use lags to account for household-specific usage in the year prior to the program.

[7] In the future, this approach could be empirically tested by comparing actual savings calculated in future program years against standard weather year results, producing a ‘realization rate’ between planned and actual savings results. Standard weather years could potentially be enhanced to better reflect these differences.

[8] We acknowledge that this approach is a proxy for estimating actual savings to allow for prospective calculation of lifetime savings. However, a substantial limitation to this approach is the issue of unobserved behavioral ramp-up that is likely to occur for future waves of participants.

As noted above, all other types of behavior programs other than residential HERs-type programs may use this adjustment protocol with appropriate persistence factors as follows. In the absence of supportable evidence for behavioral persistence for such other program types, persistence factors and measure life will not be deemed. Instead, program administrators may choose to propose and defend persistence factors and years of persistence to be used for such behavioral programs on a custom basis in concert with the independent evaluator and stakeholders,[9] on the understanding that the evaluator should then plan to retrospectively assess persistence for these programs when feasible. However, these persistence factors will be subject to evaluation risk similar to any other custom evaluation parameter.

DETERMINATION OF EFFICIENT BEHAVIOR

Behavior programs focus primarily on reducing electricity and natural gas consumption through behavioral changes; this reduction is generally measured through ex-post billing analysis after program intervention. Specific energy conservation and management behaviors are not usually directly observable. The specific definition of the efficient case is part of the design of behavioral programs and is included as part of the custom saving protocol, which will include any adjustment necessary to remove effects of program-related investments in efficient equipment.

DETERMINATION OF BASELINE BEHAVIOR

The ideal baseline for behavior programs is the energy usage without the program intervention. Various types of experimental, quasi-experimental, and/or regression-based EM&V approaches are used to present statistically valid approximations to this without-program baseline.[10] The specific definition of the baseline case is part of the design of behavioral programs and is included as part of the custom saving protocol.

DEEMED LIFETIME/PERSISTENCE OF SAVINGS

We assume here that positive savings for residential HERs-type behavior programs persist at some level for nine years beyond the initial treatment year for electric programs, giving a 10-year measure life, and for six years beyond the initial treatment year for gas programs, giving a seven-year measure life.[11] In the case of negative first-year savings, savings do not persist into the future. On-going persistent savings over those years are not equal, however; it is preferable that actual levels of ongoing savings should be calculated by future year as outlined below (see Application of Persistence for Prospective Calculations section below) to be used in cost effectiveness and lifetime savings calculations.[12] For other behavior program types without deemed measure lives and persistence factors, program administrators may choose to propose and defend years of persistence to be used on a custom basis in concert with the independent evaluator and stakeholders, on the understanding that the evaluator should then plan to retrospectively assess persistence for these programs when feasible. Alternatively, a deemed one-year measure life may be used if nothing defensible on measure life/persistence exists.

DEEMED MEASURE COST

It is assumed that most behavior changes in residential settings can be accomplished with homeowner labor only and without investment in new equipment; therefore, without evidence to the contrary, measure costs incurred by customers in such residential programs focused on motivating changes in customer behavior may be defined as $0.[13]

[9] Program Administrators may also choose to use a deemed one-year measure life in the absence of other evidence.

[10] See the Illinois Behavioral protocol set forth in the IL-TRM Attachment A: IL-NTG Methods for more information concerning randomized control trials and quasi-experimental evaluation methods for non-randomized designs for behavior programs.

[11] Determined as a reasonable assumption by Illinois TAC members. This assumption should continue to be updated as additional research is conducted on these types of programs, and additional evaluation should be undertaken to assess the reasonableness of this assumption for Illinois-specific programs.

[12] This method of applying calculated values for future year benefits is preferred. Alternatively, an effective measure life can be calculated as Effective Measure Life = Total Discounted Lifetime Savings / First Year Savings.

[13] Future evaluation of costs of behavior change is encouraged to help clarify this assumption. In addition, as noted earlier in this measure characterization, in order to ensure double counting of savings does not occur, the protocol outlined here assumes that adjustments to remove the effects of program lift have been made as part of the custom calculation of savings. In

Costs for C&I programs may include additional staffing, software purchases, etc. Cost for such programs is therefore program specific and is determined on a custom basis.

Costs incurred by Program Implementation Contractors to provide customer-specific information leading to behavior changes are considered study-based services as defined in the Illinois Energy Efficiency Policy Manual. Therefore, the full cost of these study-based services charged by the Program Implementation Contractor is the measure cost, because this is assumed to be the cost of the study-based service that would have been incurred by the Customer if the Customer were to have the study-based service performed in the absence of the efficiency Program.

LOADSHAPE AND COINCIDENCE FACTOR

While there is evidence from analysis of AMI data that the savings loadshape for residential HERs-type programs mirrors the whole-house electric energy load pattern, there are not yet enough data to develop a behavior-specific loadshape. Indications from several unpublished analyses[14] show that these behavior savings occur in a general pattern most closely approximated by the Residential Electric Heating and Cooling Loadshape (R10) than any other current residential measure loadshape; this is therefore recommended as the most reasonable approximation for use until more-specific data are available. Loadshapes and coincidence factors will need to be determined for other types of behavior programs once sufficient data are in hand.

Algorithm

CALCULATION OF SAVINGS

Throughout these protocols, Year T refers to the current reporting year for which annual savings are being determined (treatment year).[15]

ELECTRIC ENERGY SAVINGS

The algorithm shown below for this measure was developed to calculate the annual persistence-adjusted electric savings in to be reported in year T after adjustment to account for the proportion of the measured savings for that program year that actually reflects any persistent savings from prior years' program activities (Years T-1, T-2, T-3, etc.).[16]

$$\Delta kWh_{T\ Adjusted} = \Delta kWh_{T\ Measured} - \sum_{i=1}^{n} (\Delta kWh_{T-i\ Adjusted} * RR^{i} * PFE_{i})$$

Where:

$\Delta kWh_{x\ Adjusted}$ = total program annual savings for year X after adjustments to account for persistence (calculated value)

$\Delta kWh_{x\ Measured}$ = measured kWh savings: total program savings as determined from custom

a similar manner, given the savings accounted for by other utility programs are removed from the savings claims and cost effectiveness for the behavior program, the incremental costs associated with such utility program incentivized measures should also be excluded from the behavior program cost-effectiveness analysis, so as to help ensure double counting of costs does not occur in the utility portfolio cost-effectiveness analysis.

[14] Based on communication from Mathias Bell based on (currently unpublished) studies done by Opower, Cadmus, and LBNL. Also see DTE Energy: Behavior Program Measures for Submission to 2015 MEMD - Year Three Energy Savings - Demand Savings. Energy Optimization, April 15, 2014. http://www.michigan.gov/documents/mpsc/memd_2015_453673_7.pdf

[15] Calculation algorithms account for attrition of customers out of the service territory, as well as persistence decay. It has been noted that there may also be a need to adjust for cross-year effects of large differences in weather conditions or economic impacts. Custom savings inputs therefore are adjusted for standard year weather.

[16] This calculation should be carried out separately for each "wave" of behavior programs, where a wave is defined as a newly launched program. For simplicity, any new wave is assumed to start at the beginning of a program year (Year 1) and may include multiple different treatment types such as usage groups, report frequency, etc. For example, any wave added after 2022 will be considered Year 1 in the year they are launched.

calculation/billing analysis of participants in program during year X (input value)[17]

RR = a wave-specific expected retention rate for the program[18,19]

PFE_Z = Persistence factor, electric programs (deemed value)

= % savings that persist Z years after savings were initially measured

= use table below to select the appropriate value

n = number of additional years beyond first year of program delivery for which savings persist

= Illinois electric programs assumption = 9

Electric Persistence Factors[20]

Program Type = Electric Residential HERs-type (RCT)		
Application Year	Persistence Factor	
	If ΔkWh_T Adjusted >= 0	Else
Program Year T (treatment year) - record 100% of adjusted savings ($\Delta kWh_{TAdjusted}$ above)	100%	100%
Percent adjusted savings from Year T activities that persist **1 year after year T** = PFE_1	78%	0%
Percent adjusted savings from Year T activities that persist **2 years after year T** = PFE_2	61%	0%

[17] All appropriate adjustments to remove effects of participation in other utility programs, move-outs, opt-outs, to normalize for effects related to weather, and other adjustments as determined by the program experimental design, are assumed to have been made to result in this value for "measured savings". This value has been adjusted for standard year weather terms.

[18] This retention rate should be an historical average, based on multiple years of data, that applies for a given utility wave. The retention rate should be updated on a regular basis (for example, with the program planning cycles) to make sure it remains reflective of current program and economic conditions. Evaluators will decide for each wave what population the retention rate should be based on (for example: all residential customers; the entire population eligible for the program; the current program population). In making this decision, evaluators should consider data availability, how long a wave has been in the program, the customer makeup of the wave, and other factors as needed.

[19] It is possible that some savings related to behavioral programs persist even after participants move and are therefore dropped from the program. Such persistent savings could potentially occur in two ways. First, some proportion of these potential savings likely comes from efficient measures installed on the premises and not otherwise identified through other direct program participation; this component of saving could persist even under new building ownership. Second, participants who move might continue behavior changes that save energy even in a new setting; this could continue to provide savings to the program administrator if the move was within the same utility territory. As of this time, no definitive information exists as to the level of program savings related to installed measures vs. behavioral changes, making determination of these effects highly uncertain, and sufficient data may not exist to track individual customer moves. As such, this protocol assumes no persistent savings related to customers who move. Program administrators may choose to propose and defend a methodology to calculate persisting savings net of the existing RCT for the residual effects of move-outs on a custom basis in concert with the independent evaluator and stakeholders. Such a custom treatment should be based on defensible evaluation of the proportion of persisting savings from move-outs related to installed efficient measures vs. ongoing changes in behavior, utility-specific data on total customer moves within the utility territory, and appropriate management of customers who move with regard to future behavior program participation. Management of customers who move out, and the associated persisting savings of the households and premises, should not impede the ability of the program administrator to operate the program as an RCT and maintain or expand the program size (households in treatment, etc.). Such an adjustment will be subject to evaluation risk similar to any other custom evaluation parameter.

[20] See REFERENCE TABLES below for sources.

Program Type = Electric Residential HERs-type (RCT)		
Application Year	Persistence Factor	
	If ΔkWh_T Adjusted >= 0	Else
Percent adjusted savings from Year T activities that persist **3 years after year T** = PFE_3	47%	0%
Percent adjusted savings from Year T activities that persist **4 years after year T** = PFE_4	37%	0%
Percent adjusted savings from Year T activities that persist **5 years after year T** = PFE_5	29%	0%
Percent adjusted savings from Year T activities that persist **6 years after year T** = PFE_6	23%	0%
Percent adjusted savings from Year T activities that persist **7 years after year T** = PFE_7	18%	0%
Percent adjusted savings from Year T activities that persist **8 years after year T** = PFE_8	14%	0%
Percent adjusted savings from Year T activities that persist **9 years after year T** = PFE_9	11%	0%

Example of Adjusted Annual Savings Calculations:

Assume the following information on participation and measured savings for an electric HERs-type program for the following program years (all adjustments have been made to remove effects of program lift, weather, etc. within the custom savings calculations). Assume 2021 is the first year of the program/wave.

	Reporting Year						
	2021	2022	2023	2024	2025	2026	2027
Input data from program information and custom savings analysis							
# Participants (households)	120,000	109,000	103,000	99,000	94,000	90,000	88,000
kWh per participant (household)	200	250	245	250	250	265	265
kWh Measured savings (custom)	24,000,000	27,250,000	25,235,000	24,750,000	23,500,000	23,850,000	23,320,000

Expected Retention Rate of 95%

Calculation of Adjusted Annual Savings:

$\Delta kWh_{2021\ Adjusted}$ = 24,000,000 kWh

$\Delta kWh_{2022\ Adjusted}$ = 27,250,000 – (24,000,000 * 0.95 * 0.78)
= 9,466,000 kWh

$\Delta kWh_{2023\ Adjusted}$ = 25,235,000 – (9,466,000 * 0.95 * 0.78) – (24,000,000 * 0.95^2 * 0.61)
= 5,008,094 kWh

$\Delta kWh_{2024\ Adjusted}$ = 24,750,000 – (5,008,094 * 0.95 * 0.78) – (9,466,000 * 0.95^2 * 0.61) – (24,000,000 * 0.95^3 * 0.47)
= 6,156,543 kWh

$\Delta kWh_{2025\ Adjusted}$ = 23,500,000 – (6,156,543 * 0.95 * 0.78) – (5,008,094 * 0.95^2 * 0.61) – (9,466,000 * 0.95^3 * 0.47)
– (24,000,000 * 0.95^4 * 0.37)
= 5,133,637 kWh

$\Delta kWh_{2026\ Adjusted}$ = 23,850,000 – (5,133,637 * 0.95 * 0.78) – (6,156,543 * 0.95^2* 0.61) – (5,008,094 * 0.95^3 * 0.47)
– (9,466,000 * 0.95^4 * 0.37) – (24,000,000 * 0.95^5 * 0.29)
= 6,400,301 kWh

$\Delta kWh_{2027\ Adjusted}$ = 23,320,000 – (6,400,301 * 0.95 * 0.78) – (5,133,637 * 0.95^2 * 0.61) – (6,156,543 * 0.95^3 * 0.47)
– (5,008,094 * 0.95^4 * 0.37) – (9,466,000 * 0.95^5 * 0.29)
– (24,000,000 * 0.95^6 * 0.23)
= 5,579,188 kWh

Continue for future years as appropriate.

Apply the same approach to calculate adjusted annual kW and Therms, using appropriate factors and lifetimes.

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Coincident peak demand savings in year T should also be adjusted to account for persistence from previous years using a similar algorithm.[21]

If peak demand is measured directly by the custom savings analysis:

$$\Delta kW_{T\ Adjusted} = \Delta kW_{T\ Measured} - \sum_{i=1}^{n} (\Delta kW_{T\text{-}i\ Adjusted} * RR^{i} * PFE_{i})$$

Where:

[21] While there are no current studies that evaluate the persistence of peak savings, without more-specific information on the actual behaviors undertaken by program participants and their corresponding peak savings, it seems reasonable to assume that peak savings will also persist in a similar pattern; both of the approaches given assume persistence in peak savings. Further evaluation should be undertaken to clarify this point and determine appropriate peak-specific persistence values.

$\Delta kW_{X\ Adjusted}$ = total program demand savings for year X after adjustments to account for persistence (calculated value)

$\Delta kW_{X\ Measured}$ = total program demand savings as determined from custom calculation /billing analysis of participants in program during year X (input value)[22]

Other variables as defined above

If peak demand is not measured directly by the custom savings analysis, peak demand should be calculated as follows:

$\Delta kW_{T\ Adjusted}$ = ($\Delta kWh_{T\ Adjusted\ Summer}$ / #summer hours) * peak adjustment factor

Where:

$\Delta kWh_{T\ Adjusted\ Summer}$ = average adjusted electric energy savings (calculated above) for peak summer months

= $\Delta kWh_{T\ Adjusted}$ * 0.42 * (3/5)

= $\Delta kWh_{T\ Adjusted}$ * 0.25

Where:

0.42 = Summer Loadshape % for May – Sept

3/5 = proportion of May-Sept hours that fall in June, July, and Aug

summer hours = # hours in June, July, and Aug

= 8760 / 4

Where: 8760 = Hours per year

peak adjustment factor = adjustment for peak k/w over average kW for these hours

= 1.5 [23]

FOSSIL FUEL ENERGY SAVINGS

The algorithm shown below for this measure was developed to calculate the annual persistence-adjusted Therm savings in to be reported in year T after adjustment to account for the proportion of the measured savings for that program year that actually reflects any persistent savings from prior years' program activities (Years T-1, T-2, T-3, etc.).[24]

$$\Delta Therms_{T\ Adjusted} = \Delta Therms_{T\ Measured} - \sum_{i=1}^{n} (\Delta Therms_{T-i\ Adjusted} * RR^{i} * PFG_{i})$$

Where:

$\Delta Therms_{x\ Adjusted}$ = total program annual savings for year X after adjustments to account for persistence (calculated value)

$\Delta Therms_{x\ Measured}$ = total program savings as determined from custom calculation/billing analysis

[22] All appropriate adjustments to remove effects of participation in other utility programs, move-outs, opt-outs, to normalize for effects related to weather, and other adjustments as determined by the program experimental design, are assumed to have been made to result in this value for "measured savings". This value has been adjusted for standard year weather terms.

[23] Based on an approach used in Michigan that gives resulting values supported by evaluation claims. Also see DTE Energy: Behavior Program Measures for Submission to 2015 MEMD - Year Three Energy Savings - Demand Savings. Energy Optimization, April 15, 2014. http://www.michigan.gov/documents/mpsc/memd_2015_453673_7.pdf

[24] This calculation should be carried out separately for each "wave" of behavior programs, where a wave is defined as a newly launched program. For simplicity, any new wave is assumed to start at the beginning of a program year (Year 1) and may include multiple different treatment types such as usage groups, report frequency, etc.

of participants in program during year X (input value)[25]

PFG_Z = Persistence factor, gas programs (deemed value)

= % savings that persist Z years after savings were initially measured

= use table below to select the appropriate value

n = number of additional years beyond first year of program delivery for which savings persist

= Illinois gas programs assumption = 6

Other variables as defined above

Gas Persistence Factors[26]

Program Type = Gas Residential HERs-type (RCT)		
Application Year	Persistence Factor	
	If $\Delta Therms_{TAdjusted}$ >=0	Else
Program Year T (treatment year) - record 100% of adjusted savings ($\Delta Therms_{TAdjusted}$ above)	100%	100%
Percent adjusted savings from Year T activities that persist **1 year after year T** = PGE_1	70%	0%
Percent adjusted savings from Year T activities that persist **2 years after year T** = PGE_2	49%	0%
Percent adjusted savings from Year T activities that persist **3 years after year T** = PGE_3	34%	0%
Percent adjusted savings from Year T activities that persist **4 years after year T** = PGE_4	24%	0%
Percent adjusted savings from Year T activities that persist **5 years after year T** = PGE_5	17%	0%
Percent adjusted savings from Year T activities that persist **6 years after year T** = PGE_6	12%	0%

APPLICATION OF PERSISTENCE FOR PROSPECTIVE CALCULATIONS

For determination of prospective savings related to programs delivered in year T (including cost-effectiveness, lifetime savings, and cumulative prospective annual savings (CPAS)), future years' savings related to the current year activities should be recorded for this measure as savings for each specific year calculated using the table below – the current year plus 9 years of future persisting savings for electric programs, and the current year plus 6 years of future persisting savings for gas programs, in the case of positive first-year savings. Because of the

[25] All appropriate adjustments to remove effects of participation in other utility programs, move-outs, opt-outs, to normalize for effects related to weather, and other adjustments as determined by the program experimental design, are assumed to have been made to result in this value for "measured savings". This value has been adjusted for standard year weather terms.
[26] See REFERENCE TABLES below for sources.

potentially confounding effects of differences in weather in future years, the savings inputs used ($\Delta kWh_{TAdjusted}$, $\Delta kW_{TAdjusted,}$ $\Delta Therms_{TAdjusted}$) for these future-year savings calculations have been determined using weather normalized inputs. This input (to be provided by program evaluators) will approximate average savings for a standard weather year based upon historical data.[27] In the case of negative first-year savings, no savings will persist into future years.

Calculation of Future Years' Savings Related to Current Year Activities			
	Electric Programs		Gas Programs
	Electric Energy Savings	Peak Savings	Therm Savings
Program Year T: record 100% of adjusted annual savings as calculated above	$\Delta kWh_{TAdjusted}$	$\Delta kW_{TAdjusted}$	$\Delta Therms_{TAdjusted}$
Percent savings from Year T activities that persist 1 year after year T	$\Delta kWh_{TAdjusted} * PFE_1 * RR$	$\Delta kW_{TAdjusted} * PFE_1 * RR$	$\Delta Therms_{TAdjusted} * PFG_1 * RR$
Percent savings from Year T activities that persist 2 years after year T	$\Delta kWh_{TAdjusted} * PFE_2 * RR^2$	$\Delta kW_{TAdjusted} * PFE_2 * RR^2$	$\Delta Therms_{TAdjusted} * PFG_2 * RR^2$
Percent savings from Year T activities that persist 3 years after year T	$\Delta kWh_{TAdjusted} * PFE_3 * RR^3$	$\Delta kW_{TAdjusted} * PFE_3 * RR^3$	$\Delta Therms_{TAdjusted} * PFG_3 * RR^3$
Percent savings from Year T activities that persist 4 years after year T	$\Delta kWh_{TAdjusted} * PFE_4 * RR^4$	$\Delta kW_{TAdjusted} * PFE_4 * RR^4$	$\Delta Therms_{TAdjusted} * PFG_4 * RR^4$
Percent savings from Year T activities that persist 5 years after year T	$\Delta kWh_{TAdjusted} * PFE_5 * RR^5$	$\Delta kW_{TAdjusted} * PFE_5 * RR^5$	$\Delta Therms_{TAdjusted} * PFG_5 * RR^5$
Percent savings from Year T activities that persist 6 years after year T	$\Delta kWh_{TAdjusted} * PFE_6 * RR^6$	$\Delta kW_{TAdjusted} * PFE_6 * RR^6$	$\Delta Therms_{TAdjusted} * PFG_6 * RR^6$
Percent savings from Year T activities that persist 7 years after year T	$\Delta kWh_{TAdjusted} * PFE_7 * RR^7$	$\Delta kW_{TAdjusted} * PFE_7 * RR^7$	n/a
Percent savings from Year T activities that persist 8 years after year T	$\Delta kWh_{TAdjusted} * PFE_8 * RR^8$	$\Delta kW_{TAdjusted} * PFE_8 * RR^8$	n/a
Percent savings from Year T activities that persist 9 years after year T	$\Delta kWh_{TAdjusted} * PFE_9 * RR^9$	$\Delta kW_{TAdjusted} * PFE_9 * RR^9$	n/a

Where all variables are as defined above.

[27] In the future, this approach could be empirically tested by comparing actual savings calculated in future program years against standard weather year results, producing a 'realization rate' between planned and actual savings results. Standard weather years could potentially be enhanced to better reflect these differences.

Example of Calculation of Cost-effectiveness Inputs:

Assume the same information for an electric program as was used in the Example of Adjusted Annual Savings Calculations.

	Reporting Year T						
	2021	2022	2023	2024	2025	2026	2027
Annual Energy Savings = Adj. kWh savings (previously calculated) = $\Delta kWh_{TAdjusted}$	24,000,000	9,466,000	5,008,094	6,156,543	5,133,627	6,400,301	5,579,188
RR = 0.95							

Inputs for calculating cost effectiveness in 2021:

Cost-effectiveness benefit of 2021 savings in 2022 = $\Delta kWh_{2021\ Adjusted} * PFE_1 * RR$ = 24,000,000 * 0.78 * 0.95 = 17,784,000 kWh

Cost-effectiveness benefit of 2021 savings in 2023 = $\Delta kWh_{2021\ Adjusted} * PFE_2 * RR^2$ = 24,000,000 * 0.61 * 0.95^2 = 13,212,600 kWh

Cost-effectiveness benefit of 2021 savings in 2024 = $\Delta kWh_{2021\ Adjusted} * PFE_3 * RR^3$ = 24,000,000 * 0.47 * 0.95^3 = 9,671,190 kWh

Cost-effectiveness benefit of 2021 savings in 2025 = $\Delta kWh_{2021\ Adjusted} * PFE_4 * RR^4$ = 24,000,000 * 0.37 * 0.95^4 = 7,232,816 kWh

Cost-effectiveness benefit of 2021 savings in 2026 = $\Delta kWh_{2021\ Adjusted} * PFE_5 * RR^5$ = 24,000,000 * 0.29 * 0.95^5 = 5,385,515 kWh

Cost-effectiveness benefit of 2021 savings in 2027 = $\Delta kWh_{2021\ Adjusted} * PFE_6 * RR^6$ = 24,000,000 * 0.23 * 0.95^6 = 4,057,707 kWh

Inputs for calculating cost effectiveness in 2022:

Cost-effectiveness benefit of 2022 savings in 2023 = $\Delta kWh_{2022\ Adjusted} * PFE_1 * RR$ = 9,466,000 * 0.78 * 0.95 = 7,014,306 kWh

Cost-effectiveness benefit of 2022 savings in 2024 = $\Delta kWh_{2022\ Adjusted} * PFE_2 * RR^2$ = 9,466,000 * 0.61 * 0.95^2 = 5,211,270 kWh

Cost-effectiveness benefit of 2022 savings in 2025 = $\Delta kWh_{2022\ Adjusted} * PFE_3 * RR^3$ = 9,466,000 * 0.47 * 0.95^3 = 3,814,479 kWh

Cost-effectiveness benefit of 2022 savings in 2026 = $\Delta kWh_{2022\ Adjusted} * PFE_4 * RR^4$ = 9,466,000 * 0.37 * 0.95^4 = 2,852,743 kWh

Cost-effectiveness benefit of 2022 savings in 2027 = $\Delta kWh_{2022\ Adjusted} * PFE_4 * RR^5$ = 9,466,000 * 0.29 * 0.95^5 = 2,124,137 kWh

Cost-effectiveness benefit of 2022 savings in 2028 = $\Delta kWh_{2022\ Adjusted} * PFE_4 * RR^6$ = 9,466,000 * 0.23 * 0.95^6 = 1,600,427 kWh

Continue this approach for future years as appropriate.

Apply the same approach to calculate cost-effectiveness inputs for kW and for Therms, using appropriate factors and lifetimes.

REFERENCE TABLES

Persistence studies done to date for HERs-type programs capture effects through a specific time frame and only for the specific program characteristics of the programs studied. While any individual study may not accurately represent conditions in Illinois or those for all Illinois programs, the Illinois TAC has determined that an average of the implied annual decay rates across the electric- or gas-specific studies done to date (Tables 1 and 2 below) is the best currently available data to approximate persistence for the general class of residential HERs-type programs. This protocol assumes a standard decay function with a constant annual savings decay rate, where Persistence in year t = (1 – Annual Decay Rate)^t.

It is recommended that the persistence values and the length of persistence application as used in this protocol continue to be reviewed for update once every plan cycle as further longer term and Illinois-specific evaluations are undertaken.

MEASURE CODE: CC-BEH-BEHP-V06-250101

REVIEW DEADLINE: 1/1/2027

6.2 System Wide

6.2.1 Voltage Optimization

DESCRIPTION

Voltage optimization (VO)[28] is a smart grid technology that flattens voltage profiles and lowers average voltage levels on an electric power distribution grid. Lowering voltage reduces the instantaneous power consumed by customers on VO-enabled feeders,[29] which in turn results in energy and demand savings. Voltage optimization is achieved through the operation of distributed sensors, two-way communications infrastructure, remote controls on substation transformer load-tap changers, voltage regulators and line capacitor banks, and integrating/optimizing software.

Unlike energy efficiency programs that achieve savings by providing financial incentives to encourage customers to adopt energy-efficient equipment or behavioral suggestions to encourage them to adopt no-cost energy-saving behaviors, VO involves no direct customer engagement. Instead, savings are achieved by operating the voltage and reactive power controls on VO-enabled feeders in a manner designed to maintain the voltages delivered to affected customers in the lower part of the allowable voltage range.[30]

In general, reducing the voltage on a feeder reduces power consumed by the connected loads, assuming all other factors of the feeder remain constant. This is a realistic assumption for many types of consumer devices. However, there are several scenarios in which decreasing voltage does not directly result in energy and demand savings. For example, some devices (e.g., electronics) have self-contained control systems that maintain constant power consumption despite the delivered voltage. Other devices increase their power draw when presented with reduced voltage due to nonlinear inefficiencies. Still other devices (e.g., resistive heating) might decrease instantaneous power draw but operate for longer periods; thus their total energy consumption remains approximately constant (similar to the time-shifting effects of demand response programs). This means VO is more effective in reducing load for some device types than others. This may lead it to be more or less effective for specific feeders depending on the exact mix of device types the feeder has.

This measure was developed to be applicable to the following program types: Voltage Optimization. This measure is unique and does not apply to other program types.

DEFINITION OF EFFICIENT EQUIPMENT

To qualify for this measure, feeders must be enabled with VO technology and have VO fully commissioned and operational.[31]

DEFINITION OF BASELINE EQUIPMENT

The baseline assumption is a feeder without any VO technology.

[28] Voltage optimization is also referred to a volt-var optimization (VVO) or conservation voltage reduction (CVR).

[29] For the purposes of this measure, the term feeder is synonymous with circuit.

[30] The bulk of the energy savings that occurs is thus expected to occur on the customer side of the meter, although additional savings is expected from reduced current flows along the full length of the affected feeders.

[31] Note that any VO On/Off testing for the purposes of evaluation or updating the TRM will not be counted against the utility in claiming savings. VO On/Off testing is an experimental design that involves enabling and disabling the VO system under a predefined schedule for the purposes of testing its functionality. By following a predefined schedule, the VO On/Off design enables modeling of the impact of VO while controlling for factors that may vary over time, such as weather or weekday vs. weekend loads.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

VO Energy Savings can be renewed every 15 years and have a maximum measure life of 50 years[32] [33]. The renewal would claim the same savings as the original measure for an additional 15 years (up to a maximum of 50 years) after verifying that VO is still operational on the feeder in a manner consistent with the operation that led to the original TRM savings estimate. This does not preclude future consideration of (and TRM development for) a potential new measure that provides greater savings than the VO measure characterized here.

Within the EE Plan submittal ComEd and Ameren shall prepare a planned activation summary of all feeders whose energy savings are set to expire within the timeframe the EE Plan is active. This planned activation summary will indicate the planned activation status of VO feeders in an 'enabled' or 'disabled' format along with the total energy savings in MWh of each activation status. This check-in will be performed at the same cadence the EE plan is submitted. Once confirmed, the energy savings shall be credited for 15 years until the next renewal period and for a maximum of 50 years. However, if the utility ever ceases to operate VO in such a manner on any circuits, it will report such changes to evaluators and stop claiming persisting savings on such circuits in the year following the year in which operations ceased (even if less than the TRM measure life).

DEEMED MEASURE COST

The costs vary by feeder. Actual costs should be used.

LOADSHAPE

Loadshape C67 – Voltage Optimization – Ameren

Loadshape C68 – Voltage Optimization – ComEd

COINCIDENCE FACTOR

N/A

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

Annualized savings should be calculated separately for each VO-enabled feeder. The savings reductions during VO On/Off testing shall not be a basis to reduce the estimated savings.[34] The off periods from testing shall be treated as if they were on during the evaluation period.

$$\Delta kWh = kWh_{BASE} * \Delta V * CVR_f$$

Where:

[32] For ComEd, the first renewal can start in CY2033 with the renewal of CY2018 feeders. For Ameren, the first renewal can start in CY2034 with the renewal of CY2019 feeders

[33] Climate and Equitable Jobs Act (CEJA), Public Act 102-0662, "(b-20) Each electric utility subject to this Section may include cost-effective voltage optimization measures in its plans submitted under subsections (f) and (g) of this Section, and the costs incurred by a utility to implement the measures under a Commission-approved plan shall be recovered under the provisions of Article IX or Section 16-108.5 of this Act. For purposes of this Section, the measure life of voltage optimization measures shall be 15 years. The measure life period is independent of the depreciation rate of the voltage optimization assets deployed. Utilities may claim savings from voltage optimization on circuits for more than 15 years if they can demonstrate that they have made additional investments necessary to enable voltage optimization savings to continue beyond 15 years. Such demonstrations must be subject to the review of independent evaluation."

[34] VO On/Off testing is an experimental design that involves enabling and disabling the VO system under a predefined schedule for the purposes of testing its functionality. By following a predefined schedule, the VO On/Off design enables modeling of the impact of VO while controlling for factors that may vary over time, such as weather or weekday vs. weekend loads.

kWh_{BASE} = Baseline kWh consumption on the feeder per year[35]

For Ameren territory, use the average annual customer energy use for each feeder over the 2014-2016 timeframe, less energy use by exempt customers.

For ComEd territory, use annual energy consumption using the actual energy measurement during the time when VO was off (as appropriate; this may include the actual measurements prior to VO activation during the given program year and from prior program years and VO OFF periods from subsequent program years) and a calculated VO OFF value for the time when VO was on. The VO OFF baseline energy for the periods when VO is on shall be calculated using:

$$E_{VO_OFF} = \frac{E_{VO_ON}}{1 - (CVR_f * \Delta V)}$$

Where:

E_{VO_OFF} = the calculated VO OFF energy consumption when VO is on (activated)

E_{VO_ON} = the actual measured energy consumption during the period when VO is on

ΔV = the voltage reduction

CVR_f = the CVR factor

i. Where power (MW) data has not been established yet, best available data from the feeder line measurement devices should be considered.

ii. Data are clustered into bins according to temperature range,[36] season,[37] day type (weekday/weekend),[38] and hour of the day based on the VO OFF and ON statuses to create a lookup table. If multiple data points are found (i.e., same temperature range, same season, same day type, same hour of the day, and same VO status), the average of multiple references are placed into the lookup table. Various combinations of these variables may be used in an order of decreasing priority when no data points are found that match all of them.

iii. The independent evaluator shall use best practices, including an appropriate technique that is transparent, replicable, and most accurate, to address any data quality issues, with input from interested stakeholders, including ComEd.

iv. The following approach will be used for claiming kWh savings from no-load and future feeders. ComEd installs new feeders every year to accommodate area load growth. Some of them are sourced from previously claimed VO-activated substations or exist with no-load on transformers where VO is being activated in a given year. Examples of when a new feeder will be installed include, as part of a new business project to

[35] If the energy consumption baseline is measured at the feeder head, an adjustment will be made to recognize line losses and loss savings.

[36] Temperature bins are to the ceiling of the nearest 5°F interval.

[37] Seasons are defined as follows; Spring: March through May; Summer: June through August; Fall: September through November; and Winter: December through February.

[38] Weekdays are Monday to Friday and weekends are Saturday and Sunday.

accommodate a new or existing customer's load addition, or to relieve area loading congestion and contingency planning for the purpose of increasing capacity. ComEd projects load on some of these feeders over a future period, however, there are uncertainties regarding when the projected target loads will materialize.
ComEd cannot claim VO savings for a newly commissioned feeder while there is no load but can claim when a pre-defined threshold of the feeder's projected load is reached. A threshold of 70% of projected load for 6 months is adopted for ComEd.[39] To be eligible for savings, the feeder must add load to the substation transformer rather than simply splitting existing load among the feeders sourced from same transformer.

ComEd will maintain a list of existing feeders with no-load along with their projected load, to be updated as needed, and will share it with their evaluator so they can make comparisons to the threshold when the feeder is claimed. Changes can be made to the projected load, as needed, with justification. When such feeders reach the threshold of 70% of their projected load for 6 months, ComEd will notify their evaluator and provide relevant feeder and associated substation transformer data to evaluators for the purpose of verifying savings to claim in the annual impact evaluation report.

ΔV = Percentage voltage reduction on the feeder caused by VO

For Ameren territory, voltage reduction shall be calculated using a pre-post regression model (i.e., comparing pre-VO and post-VO installation). The model specification will be selected based on model fit and may vary year to year. The model will be run in accordance with the terms provided in subsections (i) through (iv) below:

i. The model utilizes pre-period (VO OFF) data from the feeders in question from the prior calendar year.

ii. Voltage (V) data is sourced from customer AMI meters. The feeder average voltage is calculated as the average of at least 70% of the AMI meters on the feeder, whenever possible.[40] AMI voltage readings are normalized by their nominal voltage before averaging voltage across the AMI meters on a given feeder.

iii. Ameren and stakeholders have agreed on a list of excludable events, during which Ameren may claim VO savings if the system is down for reasons deemed appropriate. Please see

[39] This threshold was determined based on the discussion between ComEd's Capacity planning and Voltage Optimization group. To determine the value, ComEd considered several factors including the timeline of commissioning any future feeder, load ramping up for large customers, and the comments received from ICC and Guidehouse to claim the feeders as soon as ComEd expects to have full load. ComEd considers a feeder to have reached its full load when 70% of the projected load (at the minimum) has been materialized.

[40] In cases when less than 70% of the AMI meters are programmed to record voltage data, all available meters will be used, with the goal of utilizing as close to 70% of the meters as possible.

Table 1 below for further explanation and list of excludable and non-excludable events.

iv. The independent evaluator shall use best practices, including an appropriate technique that is transparent, replicable, and most accurate, to address any data quality issues, with the input from interested stakeholders, including Ameren.

For ComEd territory, voltage reduction shall be calculated from voltage measurements taken from the feeder's head end primary voltage source using the following equation and in accordance with the terms provided in subsections (i) through (iv) below:

$$\Delta V = \left(\frac{V_{OFF} - V_{ON}}{V_{OFF}}\right)$$

v. When VO is off, the voltage if VO was on needs to be estimated and vice versa. Actual measurements shall be used for the off voltage when VO is off and the on voltage when VO is on.

vi. Data are clustered into bins in accordance to temperature range,[41] season,[42] day type (weekday/weekend),[43] and hour of the day based on the VO OFF and ON statuses to create a lookup table. If multiple data points are found (i.e., same temperature range, same season, same day type, same hour of the day, and same VO status), the average of multiple references are placed into the lookup table. Various combinations of these variables may be used in an order of decreasing priority when no data points are found that match all of them.

vii. The independent evaluator shall use best practices, including an appropriate technique that is transparent, replicable, and most accurate, to address any data quality issues, with the input from interested stakeholders, including ComEd.

viii. The counterfactual VO ON and VO OFF profiles shall be created for each feeder for the entire program year using the lookup table for temperature range,[44] season,[45] day type (weekday/weekend),[46] and hour of the day.

ix. If VO is ON in a continuous basis throughout the year, previous year's voltage data along with temperature, day type, and time of the day can be correlated in accordance to present year's temperature data, day type, and time of the day to create the VO OFF profile. This correlation shall use the data created from the most representative feeder or feeders that have undergone testing.

[41] Temperature bins are to the ceiling of the nearest 5°F interval.

[42] Seasons are defined as follows; Spring: March through May; Summer: June through August; Fall: September through November; and Winter: December through February.

[43] Weekdays are Monday to Friday and weekends are Saturday and Sunday.

[44] Temperature bins are to the ceiling of the nearest 5°F interval.

[45] Seasons are defined as follows; Spring: March through May; Summer: June through August; Fall: September through November; and Winter: December through February.

[46] Weekdays are Monday to Friday and weekends are Saturday and Sunday.

x. For the no-load and future feeders, ComEd's evaluator will use the evaluated historical transformer voltage reduction for each feeder going back to the year when the station or transformer was originally VO-enabled.[47]

CVR_f = conservation voltage reduction factor relating the change in voltage to a change in energy

= 0.80 (for both Ameren and ComEd territories)[48]

SUMMER COINCIDENT PEAK DEMAND SAVINGS

Peak demand savings should be calculated separately for each VO-enabled feeder. The savings reductions during VO On/Off testing shall not be a basis to reduce the estimated savings. The off periods from testing shall be treated as if they were on during the evaluation period.

$$\Delta kW = kW_{BASE} * \Delta V_{PEAK} * CVR_{f,PEAK}$$

Where:

kW_{BASE} = Baseline kW usage on the feeder during the peak period, defined as 1:00-5:00 pm CDT on non-holiday weekdays from June 1 to August 31.

For Ameren territory, this will be calculated as the average demand in the peak hour for each feeder over the 2014-2016 timeframe, adjusted by a calibration factor that describes the relationship between demand in the peak hour and average demand over the peak period (defined as 1:00-5:00 pm CDT on non-holiday weekdays from June 1 to August 31). This calibration factor will be calculated based on a sample of feeders for which 2014-2016 data is available.

For ComEd territory, this will be calculated in the same manner as kWh_{BASE} for energy savings but with the intent of estimating the baseline just for the peak period as opposed to for the entire year.

ΔV_{Peak} = Percentage voltage reduction on the feeder caused by VO during the peak period, defined as 1:00 – 5:00 pm CDT on non-holiday weekdays from June 1 to August 31.

For Ameren territory, this will be calculated in the same manner as ΔV for energy savings but with the intent of estimating ΔV just for the peak period as opposed to for the entire year.

For ComEd territory, this will be calculated in the same manner as ΔV for energy savings but with the intent of estimating ΔV just for the peak period as opposed to for the entire year.

$CVR_{f,PEAK}$ = conservation voltage reduction factor relating the change in voltage to a change in energy specifically for the peak period, defined as 1:00 – 5:00 pm CDT on non-holiday weekdays from June 1 to August 31

For Ameren territory, 0.68.[49]

For ComEd territory, 1.02.[50]

[47] This is recommended by ComEd to ensure consistency that all the feeders under the same transformer receive same average voltage reduction using both timeseries VO ON and OFF data from the testing period.

[48] Guidehouse. 2020. *Supporting Documentation for Voltage Optimization TRM Measure*. <Add hyperlink when available>

[49] Ibid.

[50] Ibid.

EXCLUDABLE AND NOT-EXCLUDABLE EVENTS IN CALCULATING ELECTRIC SAVINGS

Both Ameren and ComEd have established a set of excludable (where VO is off, but savings can be claimed as if VO is on) and not-excludable (where VO is off, and savings cannot be claimed) events. These events can be accounted for either by: 1) determining the percentage of time non-excludable events occur and de-rating the savings by this percentage (ComEd's approach), or 2) removing the excludable events from the dataset used to calculate savings (Ameren's approach).

Below are tables of events each utility has established as excludable and non-excludable. Changes or additions can be made to these tables with the consensus of the utilities, the independent evaluator, and ICC staff (none of whose consensus shall not be unreasonably withheld).

Table 1. Ameren Excludable and Non-Excludable VO Events

Event	Description	Reason/Explanation	Category
Feeder Outage	Anytime the majority of a feeder is out due to any reason.	Feeder outages are typically not predictable or planned and are outside of Ameren's control. They are an anomaly and are not certain to occur on the same feeder in subsequent years.	Excludable
Repair / Maintenance	Repair or maintenance work is performed on a VO feeder causing VO to be disabled.	Repair and maintenance of Ameren's system is an operational necessity to provide customers with safe and reliable electric service. These events are not certain to occur on the same feeder in subsequent years.	Excludable
Switching	Dispatch disables VO on the feeder for any necessary switching event.	Ameren will perform switching for storms, outages, repair, maintenance, safety, and work to support new customer growth. These events are not certain to occur on the same feeder in subsequent years.	Excludable
Technology	A failure of the Information and/or Communication Technology which results in "all" VO feeders being disabled simultaneously due to events outside of Ameren's control.	VO is dependent upon third party infrastructure that Ameren has no control over. Examples include the loss of the cellular communications network (AT&T and Verizon), the failure of the VO Software provided by the outside vendor, or a Cyber event. Events of this nature are an anomaly and are not certain to occur year after year. This event is not predictable or planned and is outside of Ameren's control.	Excludable
Worldwide Pandemic / Orders by Civil Authorities	Repairs and maintenance may take longer due to limited crew availability or other restrictions/priorities. Example: COVID-19	Due to restrictions, repairs and maintenance may take longer. This reasonable delay is outside the control of Ameren.	Excludable
Disaster Recovery (DR) Testing	Ameren periodically performs Disaster Recovery testing on systems (AMI, ADMS, VO, etc.) which could result in VO disabling. Typically all VO feeders would be affected during DR testing.	Disaster Recovery is necessary and critical to ensure that Ameren can operate safely and effectively during an unforeseen event.	Not-Excludable

Event	Description	Reason/Explanation	Category
Server patching/issues	Anytime servers go down or patching takes place and the VO system does not come back online due to servers not rebooting correctly.	Events of this nature are unavoidable, but should be addressed by Ameren in a timely fashion. This should result in negligible impacts to energy savings.	Not-Excludable
Configuration Changes	Anytime VO is disabled for making updates to the Orion, go-live testing, or to make changes on the system resulting in shutting down services.	Events of this nature are unavoidable, but should be addressed by Ameren in a timely fashion. This should result in negligible impacts to energy savings.	Not-Excludable
VO field hardware failures	The loss or failure of a voltage regulator control, LTC control, or switched capacitor control on a feeder.	Events of this nature are unavoidable, but should be addressed by Ameren in a timely fashion. This should result in negligible impacts to energy savings.	Not-Excludable
Loss of communications	Anytime a device has a communications failure that would result in VO disabling. This event does not include 3rd party cellular communications network (AT&T and Verizon) failures.	Events of this nature are unavoidable, but should be addressed by Ameren in a timely fashion. This should result in negligible impacts to energy savings.	Not-Excludable

Table 2. ComEd Excludable and Non-Excludable VO Events

Event	Description	Reason/Explanation	Category
System Operational Requirements	OCC takes control and disables VO due to station/feeder out of configuration, major alarm, repair/maintenance or switching events.	Feeder outages are typically not predictable or planned and are outside of ComEd control. ComEd will take necessary steps to ensure the reliability and safety of the system during storms and outages, maintenance, and work to support new customer growth. These events are not certain to occur on the same feeder in subsequent years.	Excludable
Loss of communication	Any unplanned interruption to the communication network.	Natural causes or unplanned repair due to equipment failure occasionally disrupting communication network.	Excludable
VO Control System	System component failure requires vendor upgrade or revision.	The failure of the VO Software provided by the outside vendor (OSI), or a Cyber event. Events of this nature are an anomaly and are not certain to occur year after year. This event is not predictable or planned and is outside of ComEd's control.	Excludable
VO On/Off Cycling Schedule	Supervision over the transitional states from on to off, and vice versa.	When adding or commissioning substations or feeders to the VO Control system.	Excludable
Customer Maintenance	VO is disabled to investigate power quality issues.	Possible VO deactivation may be required to facilitate certain investigation requirements.	Not-Excludable
Worldwide Pandemic / Orders by Civil Authorities	Repairs and maintenance may take longer due to limited crew availability or other	Due to restrictions, repairs and maintenance may take longer. This reasonable delay is outside the control of ComEd.	Excludable

Event	Description	Reason/Explanation	Category
	restrictions and priorities. Example: COVID-19		
VO Control System	Anytime VO system fails to operate due to model error in VO software, or inappropriate manual settings (human error).	Events of this nature should be addressed by ComEd in a timely manner, resulting in negligible impacts to energy savings.	Not-Excludable
Loss of communication	Any planned system upgrade that interrupts communication.	Planned system patching or upgrades interfere with the communication network and disable VO. This should be addressed by ComEd in a timely manner, resulting in negligible impacts to energy savings.	Not-Excludable
Equipment	Equipment failure that results in VO feeders being disabled (MJ5/DCIAB).	The equipment failure should be addressed by ComEd in a timely manner. This should result in negligible impacts to energy savings.	Not-Excludable
Server patching/ issues	Anytime servers would go down or if patching took place and VO system did not come back online due to servers not rebooting correctly.	Events of this nature are unavoidable but should be addressed by ComEd in a timely manner. This should result in negligible impacts to energy savings.	Not-Excludable

FOSSIL FUEL SAVINGS

N/A

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

VO may provide non-monetized energy benefits in the form of improved ability to manage the grid "downstream" of the substation. This could result in improved reliability, lower spending on other grid improvements, or both. Further research is needed to understand the scope and impact of these potential benefits. There are no water savings or non-energy impacts from VO.

DEEMED O&M COST ADJUSTMENT CALCULATION

There are annual O&M costs incurred by the utility as a result of implementation of VO. Cost-effectiveness analysis should include estimates of annual O&M costs over the initial 15-year period and then for each incremental renewal period up to 50 years of the VO investment, discounted to present value for the year in which the VO investment is being analyzed. O&M cost estimates should include (a) labor and equipment costs to maintain the system and (b) third-party software costs.

MEASURE CODE: CC-SYS-VOPT-V03-230101

REVIEW DEADLINE: 1/1/2028

Consistent with the definition of Review Deadline in TRM Volume 1 (Overview), the Voltage Optimization working

group collectively acknowledges that this date does not represent a commitment or obligation to revise TRM content by this date.

6.3 Purchasing Tools

6.3.1 Efficient Choice Tool

DESCRIPTION

Efficient Choice (EC) is an online platform that facilitates energy efficient retail purchases. Users[51] can compare products in a wide range of electric and gas residential product categories, including but not limited to home appliances, consumer electronics and heating and cooling equipment. Users may choose from among current retail offers and are redirected to retailer websites to purchase. EC is designed to eliminate market, cognitive, and psychological barriers to the adoption of energy efficient products through comparisons that include product specifications, pricing, information on energy consumption, and a number of other pieces of information.

Because EC does not track "participants," estimation of savings is reliant on a combination of observed website traffic and surveys of utility customers who may have engaged with the website.[52] Program tracking data and survey responses are used to identify utility customers who engaged with EC, estimate those customers' purchase rates for product categories found on the site, and the proportions of those purchases that were energy-efficient and did not receive an incentive through another energy efficiency program. Whenever available, program tracking data should be used before self-reported survey results. Surveys include a verification component to validate energy-efficient purchases reported by survey respondents.

Observed website traffic is then used to estimate the number of unique customers who have engaged with the website, referred to as "unique active shoppers" (for further detail, please see the Unique Active Shoppers section of this measure). Unique active shopper counts are then used to scale estimated energy-efficient purchase quantities to the population of unique active shoppers to estimate the total number of energy-efficient products purchased by unique active shoppers. Per-unit savings are then estimated using the most appropriate measure-specific IL-TRM specifications.

DEFINITION OF EFFICIENT EQUIPMENT

The specific definitions of the efficient case vary by type of equipment purchased. For many common product categories (for example, clothes washers), definitions of the efficient case are provided in Volume 3 of the IL-TRM, and should be used. For categories of equipment not yet characterized in the IL-TRM, provisional efficient case definitions can be used at evaluation discretion.

DEFINITION OF BASELINE EQUIPMENT

The specific definitions of the baseline case vary by type of equipment purchased. For many common product categories (for example, clothes washers), definitions of the baseline case are provided in Volume 3 of the IL-TRM, and should be used. For categories of equipment not yet characterized in the IL-TRM, provisional baseline case definitions can be used at evaluation discretion.

DEEMED LIFETIME OF EFFICIENT EQUIPMENT

Measure lives should be sourced from the product category's corresponding measure in Volume 3 of the IL-TRM. For categories of equipment not yet characterized in the IL-TRM, provisional measure lives can be used at evaluation discretion.

DEEMED MEASURE COST

Incremental costs should be sourced from the product category's corresponding measure in Volume 3 of the IL-TRM by default. At evaluation discretion, deviations from IL-TRM specified incremental costs can be made with sufficient

[51] As currently implemented, EC is typically a publicly-facing website and can be used by anyone.

[52] Discussion of the identification of the population of utility customers who may have engaged with EC and therefore should be included in evaluation research is outside of the scope of the IL-TRM.

justification.

LOADSHAPE

N/A

COINCIDENCE FACTOR

Per-unit demand savings for each product category should apply coincidence factors from corresponding measure in Volume 3 of the IL-TRM.

PURCHASE RATES

Survey research should inform purchase rates for each product category and each utility's EC. These rates, broadly, reflect the portion of customers who engaged with each product category and went on to purchase non-rebated energy-efficient products. Purchase rates should not count rebated or non-energy efficient products as EC purchased measures. Purchase rates should be calculated as the product of the four survey-based response ratios from EC participants that actively engaged with the EC site. These include:

1) The portion of EC users who reported purchasing a product of any efficiency level after engaging with the respective product category on the EC website
2) The portion of customers who purchased a product of any efficiency level who reported purchasing a product that did not receive any form of utility rebate;
3) The portion of customers who purchased a non-rebated product who reported purchasing an efficient product; and
4) The portion of customers who reported an efficient purchase who were able to verify the efficiency of this product by providing the manufacturer model number or SKU.

The equation below describes the calculation of product level a purchase rate formulaically.

$$Purchase\ Rate = \frac{Number\ of\ self\ reported\ purchases}{\substack{Total\ number\ of\ self\ reported\ EC\ users\ who\\ engaged\ with\ the\ respective\ product\ category}} X \frac{Number\ of\ purchases\ without\ a\ utility\ rebate}{Number\ of\ self\ reported\ purchases} X \frac{Number\ of\ self\ reported\ efficient\ purchases}{Number\ of\ purchases\ without\ a\ utility\ rebate} X \frac{Number\ of\ verified\ efficient\ purchases}{\substack{Number\ of\ self\ reported\ efficient\ purchases\ with\\ verifiable\ efficiency\ ratings}}$$

Purchase rates should be determined through evaluation. The targeted confidence and precision for purchase rates should also be determined by the evaluator.

In some cases, like measures may be grouped together if there is not enough EC activity for individual evaluation. For example, televisions and monitors can be grouped under an overall electronics purchase rate. The grouping of measures under a single purchase rate should be determined by the evaluator.

Purchase rates may be deemed for future use after research of specific product categories. Deemed purchase rates should be reevaluated as determined by evaluators and/or the TAC.

PURCHASE QUANTITY

For some measures presented on EC, customers can purchase multiple units. Purchase quantities should be determined through evaluation.

For measures purchased with utility rebates, their associated energy, demand, water and natural gas savings should be claimed by the program incentivizing the measure. Savings from measures receiving rebates should not be claimed by EC as detailed in the purchase rate section above.

UNIQUE ACTIVE SHOPPER COUNT

The count of unique active shoppers is based on observed web traffic associated with each product category and should reflect the total number of EC visitors that actively engaged with the product. Active engagement is defined as an EC visitor who conducted at least one of ten specific actions on the site.[53] These values should be provided by implementer staff for the duration of the participation period and verified through evaluation.

Algorithm

CALCULATION OF ENERGY SAVINGS

ELECTRIC ENERGY SAVINGS

$$\Delta kWh = PR \times Qty \times UAS \times kWh_{per}$$

PR = Purchase rate (defined above).

Qty = Average purchase quantity

UAS = Count of Unique Active Shoppers for each product category

kWh_{per} = Develop unitary electric energy savings based on the measure's corresponding TRM section

kWh_{per} should include secondary kWh savings where appropriate.

Summer Coincident Peak Demand Savings

$$\Delta kW = PR \times Qty \times UAS \times kW_{per}$$

kW_{per} = Develop unitary demand savings based on the measure's corresponding TRM section.

FOSSIL FUEL SAVINGS

$$\Delta Therms = PR \times Qty \times UAS \times Therms_{per}$$

$Therms_{per}$ = Develop unitary therm savings based on the measure's corresponding TRM section.

WATER AND OTHER NON-ENERGY IMPACT DESCRIPTIONS AND CALCULATION

$$\Delta Water\ (gallons) = PR \times Qty \times UAS \times \Delta Water_{per}$$

Where

ΔWater (gallons) = Water saved, in gallons

$\Delta Water_{per}$ = Develop unitary water savings based on the measure's corresponding TRM section.

DEEMED O&M COST ADJUSTMENT CALCULATION

MEASURE CODE: CC-PTS-ECT-V01-230101

REVIEW DEADLINE: 1/1/2025

[53] Actions include: (1) recommendations engaged, (2) product selected, (3) product list sorted, (4) product list filtered, (5) histogram engaged, (6) product favorites engaged, (7) search saved, (8) offer clicked, (9) compare button engaged, (10) compare started.

2026 Illinois Statewide Technical Reference Manual for Energy Efficiency Version 14.0

Attachment A

Illinois Statewide Net-to-Gross Methodologies

Effective for Evaluation

All NTG data collection and analysis activities for the program types covered by this document shall conform to the NTG methods set forth herein.

Attachment A: Illinois Statewide Net-to-Gross Methodologies

1 Policy Context for this Information

Starting in 2014, the Illinois Evaluation Teams (Cadmus Group, Itron, Navigant Consulting, Opinion Dynamics, Ridge & Associates) worked with the Illinois Stakeholder Advisory Group (SAG) to create an Illinois Statewide Net-to-Gross (NTG) Methodologies document (IL-NTG Methods). This document has been updated annually, including with input from the current Illinois Evaluation Teams (Guidehouse, Opinion Dynamics, Ridge & Associates, and Verdant). The IL-NTG Methods document is included as an attachment to the Illinois Statewide Technical Reference Manual for Energy Efficiency (IL-TRM). Through five different dockets, the Illinois Commerce Commission (ICC) has directed the Evaluation Teams to compile and formalize standard NTG methods for use in Illinois energy efficiency (EE) evaluation, measurement, and verification (EM&V) work. The ICC EE dockets are shown in the following table.

Table 1-1. ICC Energy Efficiency Dockets

ICC Order Docket No. and Date	Program Administrator	NTG Discussion – Order Pages	ICC Link
13-0495 (1/28/14)	Commonwealth Edison Company (ComEd)	129-130	http://www.icc.illinois.gov/downloads/public/edocket/367591.pdf
13-0498 (1/28/14)	Ameren Illinois Company (Ameren)	167, 171	http://www.icc.illinois.gov/downloads/public/edocket/367603.pdf
13-0499 (1/28/14)	Illinois Department of Commerce & Economic Opportunity (Department of Commerce)	20, 23, 49	http://www.icc.illinois.gov/downloads/public/edocket/367581.pdf
13-0549 (5/20/14)	Nicor Gas Company (Nicor)	41-42, 78	http://www.icc.illinois.gov/downloads/public/edocket/378494.pdf
13-0550 (5/20/14)	North Shore Gas Company (North Shore Gas) and The Peoples Gas Light and Coke Company (Peoples Gas) (collectively, PG&NSG)	54-55, 66	http://www.icc.illinois.gov/downloads/public/edocket/378495.pdf

To provide clarity to the ICC directives, the relevant section on IL-NTG Methods is shown in its entirety from the Nicor Gas Order (Docket No. 13-0549). The Nicor Gas Order provides the most detail on the ICC NTG directive in comparison to the other EE orders. The Nicor language is as follows:

> The Commission believes that Staff's recommendations concerning Commission adoption of consistent statewide net-to-gross methodologies ("IL-NTG Methods") for use by the evaluators are reasonable and will aid in future evaluation of the energy efficiency programs. To help ensure the independence of the evaluators, to improve efficiency in the evaluation process, and to ensure programs across the state as delivered by the various Program Administrators can be meaningfully and consistently evaluated, the Commission hereby adopts Staff's recommendation that consistent IL-NTG Methods be established for use in the evaluations of comparable energy efficiency programs offered by different Illinois Program Administrators. The Commission notes that Section 8-104(k) of the Act encourages statewide coordination and consistency between the gas and electric energy efficiency programs and Staff's proposal would help ensure consistency in the evaluation of program performance. The Commission notes that this directive is not to create entirely "new" NTG methodologies for every energy efficiency program, but rather to assess NTG methodologies and survey instruments that have been used to evaluate energy efficiency programs offered in Illinois, and to compile the most justifiable and well-vetted methodologies (or potentially combine certain components from the existing approaches to better represent the most justifiable and well-vetted method consistent with best practices) in an attachment to the Updated IL-TRM that would

get submitted to the Commission for approval. The Commission notes that the IL-NTG Methods will be flexible and adaptable to multiple program designs and budgets and tailored to appropriately assess the specifics of each of the Program Administrators' energy efficiency programs, consistent with standard NTG methodologies adopted in other states that were filed in this proceeding. The Commission agrees with Staff that in the interest of efficiency, the current program evaluators should take the lead in compiling and formalizing standard methodologies for NTG in Illinois taking into consideration SAG input. Because the existing Plan 1 evaluators are under contract with the Company for the evaluation of the program year three energy efficiency programs, it is appropriate for these existing evaluators to work on and complete the compilation of the IL-NTG Methods over the next year. The Commission recognizes that each year considerable time may be spent vetting NTG methodologies for each program evaluation separately for each utility under the existing evaluation plan review practices; adoption of IL-NTG Methods would save on these limited evaluation resources by having a common reference document for the evaluators to use in estimating net savings for Illinois.

The Commission hereby directs the Company to require its evaluators to collaborate with the other Illinois evaluators and the SAG to use best efforts to reach consensus on the approaches used in assessing NTG in particular markets for both residential and non-residential energy efficiency programs in a manner consistent with the direction described herein. (Pages 41-42)

(16) Northern Illinois Gas Company shall require its evaluators to collaborate with the other Illinois evaluators and the SAG to reach consensus on the most defensible and well-vetted methodologies for assessing net-to-gross ratios in particular markets for both residential and non-residential energy efficiency programs in a manner consistent with the direction provided herein.

(17) ICC Staff shall file the agreed-upon consensus statewide NTG methodologies with the Commission as an attachment to the Updated IL-TRM, and if consensus is not reached on a certain component of the statewide NTG methodologies, that particular non-consensus component should be submitted in a manner consistent with the approach used for non-consensus IL-TRM Updates. (Page 78)

1.1 Programs Currently Covered in this Document

This document is intended to cover the majority of residential and non-residential programs offered in Illinois.[54] Programs covered as of the writing of this document are listed in tables at the beginning of Section 3: 3 Commercial, Industrial, and Public Sector Protocols and Section 0: 4 Residential and Low Income Sector Protocols. If the design of a given program changes significantly, then it may mean that the NTG protocol listed for that program in this document is no longer appropriate. If that happens, the evaluator should follow the procedures outlined below under Section 1.4: Diverging from the IL-NTG Methods.

This document will be updated over time to incorporate new programs and to reflect recommended changes to existing methodologies. All NTG data collection and analysis activities for the program types covered by this document shall conform to the NTG methods set forth herein.

1.2 Updating the IL-NTG Methods

This attachment is part of the IL-TRM and follows the timeline for updating of the IL-TRM, as specified in the

[54] Evaluation reports on those programs can be found at http://www.ilsag.info/evaluation-documents.html.

Illinois Energy Efficiency Policy Manual. In general, the following will take place:

- Updates will generally occur annually.
- Any changes to the IL-NTG Methods document will be circulated to the full SAG, and SAG participants will have a ten business day review process.
- Updates may be discussed within the SAG throughout the year but will be completed annually.
- Annually, the ICC Staff will submit a Staff Report (with the consensus Updated IL-TRM attached) to the Commission with a request for expedited review and approval.
- Updated NTG methods go into effect upon SAG approval, which may be before the annual TRM update or before the effective date of the updated TRM.

1.3 Diverging from the IL-NTG Methods

The NTG methods for the programs outlined in this document are partially binding. The criteria for deviating from the IL-NTG Methods document are set forth below. In all cases, the evaluators (or any interested stakeholder) submits the proposed deviation to the full SAG for a ten business day SAG review and comment period. In the event of an objection by a SAG participant, efforts may be made to see if consensus can be reached on the proposed deviation in a subsequent monthly SAG meeting. In this case, a final opportunity for SAG review and comment to the proposed deviation will be provided following the SAG meeting.

Evaluators may modify the approaches described in this document if the following three conditions have been satisfied:

1. Evaluators must explicate within the annual evaluation research plan (or another document) how specific items in the proposed modified NTG method will diverge from what is written in this document. Evaluators must justify why the divergence is appropriate.
2. Prior to the use of the modified NTG method for a particular program, evaluation teams must be in agreement on the use and execution of the modified NTG method.
3. Any objection from SAG participants regarding the proposed modified NTG method is resolved.

Evaluators may test alternative methods of estimating NTG for a particular program in addition to the NTG methods outlined in this document, if the following three conditions have been satisfied:

1. Evaluators must explicate within the annual evaluation research plan (or other document) the proposed alternative NTG method. Evaluators must explain why the proposed alternative NTG method might be superior to the NTG methods outlined in this document for the particular program. Evaluators must discuss the foundation for expecting that the proposed alternative NTG method is likely to produce meaningful results.
2. Prior to the use of the alternative NTG method for a particular program, evaluation teams must be in agreement on the key details of the approach for implementing the alternative NTG method.
3. Any objection from SAG participants regarding the proposed alternative NTG method gets resolved.

When performing alternative NTG methods for a particular program, the choice of methods may vary across the state. For example, if ComEd's evaluator chooses to test Methods 1 and 2 for a particular program, Ameren's evaluators do not also have to perform Methods 1 and 2 for a similar program.

Several sections of this attachment provide example questions that can be used to collect the data required in the NTG algorithms. Adjustments to refine specific question wording, e.g., to better reflect the design of the evaluated program, do not constitute divergence from the IL-NTG Methods. Evaluators are not required to use the exact wording provided in the example questions.

1.4 Procedure for Non-Consensus Items

Non-consensus items that arise during the development and updating of the IL-NTG Methods document will be handled in substantially the same way as non-consensus IL-TRM Updates are addressed. The approach to be used is as follows.

- Once the Illinois NTG Working Group[55] has progressed as far as they can on the methodology, and it has been found that there is non-consensus on a specific Net-to-Gross Methods topic or procedure, the Illinois NTG Working Group shall submit to the ICC Staff and the SAG's Technical Advisory Committee (TAC) a "Comparison Exhibit of Non-Consensus Net-to-Gross Methods topics/procedures" within two weeks after the Illinois NTG Working Group has failed to reach consensus. The TAC will then deliberate on the issue with a goal of reaching consensus.
- If consensus does not emerge in the TAC regarding a particular Net-to-Gross Methods topic or procedure, the "Comparison Exhibit of Non-Consensus NTG Methods topics/procedures" is then sent to the full SAG for their deliberations and input. The SAG provides a forum where experts on all sides of the contested issue can present their expert opinions in an effort to inform parties of the contested issue and to also facilitate consensus.
- To the extent a consensus among Program Administrators and non-financially interested stakeholders cannot be reached regarding issues related to specific Net-to-Gross Methods topic or procedure updates, the IL-TRM Administrator shall have the authority to use its best judgment to propose a resolution of the issue and include such in the updated IL-TRM that gets submitted to the ICC for approval. For transparency and informational purposes, the ICC Staff will document such dispute and include a link to a "Comparison Exhibit of Non-Consensus Net-to-Gross Methods topics/procedures" developed by the Illinois NTG Working Group and the IL-TRM Administrator in the Staff Report submitted to the Commission. The "Comparison Exhibit of Non-Consensus Net-to-Gross Methods topics/procedures" will document, with input from the parties, the various parties' positions concerning a non-consensus Net-to-Gross Methods topic or procedure update as well as the IL-TRM Administrator's rationale for its decision to resolve the issue.
- Nothing in this language shall preclude Program Administrators and stakeholders from challenging the IL-TRM Administrator's proposed resolution by petitioning the Commission. Until the Commission resolves the petition, the Commission-approved Net-to-Gross Methods topic or procedure shall be the default pending the issuance of a Commission Order. The applicable date for the Commission-resolved Net-to-Gross Methods topic or procedure will be the latter of January 1 of the year the IL-TRM was designed to go into effect, or the first day of the next month following the Commission order. In the petition, the filing party should note all Program Administrators affected by the IL-TRM dispute, and request that the Commission join each affected Program Administrator to the docket.

[55] The Illinois NTG Working Group consists primarily of the subset of Evaluators deliberating on NTG methodologies; however, any interested party may participate in the Illinois NTG Working Group.

2 Attribution in Energy Efficiency Programs in General

One of the most difficult aspects of evaluation, and not just within evaluation of energy efficiency programs, is attributing results to a program. Attribution provides credible evidence that there is a causal link between the program activities and the outcomes achieved by the program. Attribution research estimates the difference between the outcomes and those that would have occurred absent the program (i.e., the counterfactual). Put in research terms, evaluators must reject the null hypothesis of no causality through probabilistic statements (e.g., "strong evidence"; "high probability"). As such, it is important to realize that the concept of the counterfactual cannot be proven with certainty. So even though the NTG ratio is a single value, conceptually it is a probabilistic statement.[56] One of the main academics within evaluation stated that there is a "…total and inevitable absence of certain knowledge [arising] from the methods social scientists use" when assessing the counterfactual. (Shadish, et al., 2002) This statement is not about poor methods, but about the counterfactual itself. Because programs work with people and are usually not a laboratory experiment that can be replicated over and over[57] to find out what actions people would have taken absent an intervention, one would need a time machine to take people back in time and not provide the program. Since time machines do not exist, evaluators have developed methods that approximate the counterfactual to the best of their ability.

2.1 Definitions

For energy efficiency programs, evaluators differentiate between savings at a "gross" and "net" level as described below in the short set of relevant definitions. These definitions are not all encompassing or meant to restrict evaluation in any way, but to provide context before additional detail is provided in later sections. Research to determine attribution occurs to allow for a better understanding of the net level of savings.

Table 2-1. Definitions

Concept	Term	Definition
Consumers	Nonparticipant	Any consumer who was eligible but did not participate in the subject efficiency program, in a given program year.
	Participant	A consumer who received a service offered through the subject efficiency program, in a given program year; also called program participant. The term "service" is used in this definition to suggest that the service can be a wide variety of inducements, including financial rebates, technical assistance, product installations, training, energy efficiency information, or other services, items, or conditions. Each evaluation plan should define "participant" as it applies to the specific evaluation.
Gross Impacts	Gross Impacts	The change in energy consumption and/or demand that results directly from program-related actions taken by participants in an energy efficiency program, regardless of why they participated.
Attribution of Impacts	Net Impacts	The change in energy consumption and/or demand that is attributable to a particular energy efficiency program. This change in energy use and/or demand may include, implicitly or explicitly, consideration of factors such as free ridership, participant and nonparticipant spillover, and induced market effects. These factors may be considered in how a baseline is defined (e.g., common practice) and/or in adjustments to gross savings values.
	Net-to-Gross Ratio	A factor representing net program savings divided by gross program savings that is applied to gross program impacts to convert them into net program impacts. The factor itself may be made up of a variety of

[56] A probabilistic statement is not the same as the confidence and precision information calculated based on sampling theory.
[57] However, a small number of program designs do lend themselves to experimental or quasi-experimental designs that allow for regression analysis of net impacts.

Concept	Term	Definition
		factors that create differences between gross and net savings, commonly including free riders and spillover. The factor can be estimated and applied separately to either energy or demand savings. Note that the net-to-gross ratio (NTGR) = ((1-Free Ridership) + Participant Spillover + Nonparticipant Spillover).
	Core NTGR	1-Free Ridership
	Free Rider	A program participant who would have implemented the program's measures or practices in the absence of the program. Free riders can be: (1) total, in which the participant's activity would have completely replicated the program measure; (2) partial, in which the participant's activity would have partially replicated the program measure; or (3) deferred, in which the participant's activity would have partially or completely replicated the program measure, but at a future time.
	Spillover	Reductions in energy consumption and/or demand caused by the presence of an energy efficiency program. There can be participant and/or nonparticipant spillover. *Participant spillover* (PSO) is the additional energy savings that occur as a result of the program's influence when a program participant independently installs incremental energy efficiency measures or applies energy-saving practices after having participated in the energy efficiency program. Evaluated savings associated with Program Administrator Training programs will also be considered Participant spillover.* There are several general categories of participant spillover: • *Inside spillover* (ISO): Occurs when program participants implement additional program-induced energy efficiency measures at the program project site. • *Outside spillover* (OSO): Occurs when program participants implement program-induced efficiency measures at other sites within the Program Administrator's service territory at which program project measures were not implemented. • *Like spillover:* Occurs when program participants implement program-induced efficiency measures of the same type as those implemented through the program. Like spillover can occur at the program project sites (ISO) or at other sites within the Program Administrator's service territory (OSO). • *Unlike spillover:* Occurs when program participants implement program-induced efficiency measures of a different type from those implemented through the program. Unlike spillover can occur at the program project sites (ISO) or at other sites within the Program Administrator's service territory (OSO). *Nonparticipant spillover* (NPSO) refers to energy savings that occur when a program nonparticipant installs energy efficiency measures or applies energy savings practices as a result of a program's influence.
Markets	Market	The commercial activity (e.g., manufacturing, distributing, buying, and selling) associated with products and services that affect energy use.
	Market Effects	A change in the structure of a market or the behavior of participants in a market that is reflective of an increase (or decrease) in the

Concept	Term	Definition
		adoption of energy efficient products, services, or practices and is causally related to market interventions (e.g., programs). Examples of market effects include increased levels of awareness of energy-efficient technologies among customers and suppliers, increased availability of energy-efficient technologies through retail channels, reduced prices for energy-efficient models, build-out of energy-efficient model lines, and—the end goal— increased market shares for energy-efficient goods, services, and design practices.
	Market Assessment	An analysis that provides an assessment of how and how well a specific market or market segment is functioning with respect to the definition of well-functioning markets or with respect to other specific policy objectives. A market assessment generally includes a characterization or description of the specific market or market segments, including a description of the types and number of buyers and sellers in the market, the key factors that influence the market, the type and number of transactions that occur on an annual basis, and the extent to which market participants consider energy efficiency an important part of these transactions. This analysis may also include an assessment of whether a market has been sufficiently transformed to justify a reduction or elimination of specific program interventions (or whether continued or even increased intervention is necessary). Market assessment can be blended with strategic planning analysis to produce recommended program designs or budgets. One particular kind of market assessment effort is a baseline study, or the characterization of a market before the commencement of a specific intervention in the market for the purpose of guiding the intervention and/or assessing its effectiveness later.

* This definition does not apply to Building Operator Certification (BOC) when using IL-TRM defined prescriptive savings. IL-TRM defined prescriptive savings for BOC are considered net and are not subject to any further NTG adjustment.

2.2 Free Ridership-Specific Issues

2.2.1 Survey Design

Free ridership questions, especially questions about the counterfactual, can be challenging to answer and may confuse respondents. To address these challenges, evaluators may use the following survey design strategies:

- Warm up questions
- Clarification of key terms

Warm up Questions

Warm up questions preface the counterfactual questions to remind the respondent of their state of mind when they decided on the efficient option. Examples of warm up questions are as follows:

1. How did you first learn about the energy efficient option of this [MEASURE]?
2. How did you first learn about the following features of this energy efficient [MEASURE]:
   A. The potential to save energy and lower your utility bill?
   B. The environmental benefits?
   C. The potential to reduce maintenance costs?

D. The home comfort benefits?
E. The price difference between this energy efficient [MEASURE] and one of standard efficiency?

Responses to warm up questions are not to be used to calculate free ridership. They are intended to improve the quality of responses to free ridership questions by reminding the respondent of their process to choose the energy efficient option.

Clarification of Efficiency Terms

To highlight that free ridership questions focus on the process of choosing an efficient option over one of standard efficiency, evaluators may clarify the terms used to describe the options before asking the questions. For example:

> "Next we will ask you about your decision to purchase the energy efficient [measure] instead of one of standard efficiency. By "energy efficient" we mean the equipment performs just as well or better than equipment of standard efficiency, but the energy efficient equipment uses less energy to do so. Energy efficient equipment typically costs more than standard models, but they cost less to operate and often cost less to maintain than standard models do."

Prefacing counterfactual questions with clarifications of efficiency terms may highlight for the respondent that the questions center on choosing the efficient option – not on the need to replace the existing equipment (with a model of any efficiency).

2.2.2 Supplementing Self-Report with Historical Tracing

For programs with projects that are large, complex, involve multiple decision-makers, and are the result of many decisions made over the course of the project (for example, custom and new construction programs), evaluators may review project documentation to supplement their analysis of self-report survey results. Historical tracing, which involves reconstructing the events that led to the outcome of interest, can support logic to enhance the validity of the free ridership estimation from self-report survey results[58]. By considering additional qualitative and quantitative information, such as project files, documented communication, as well as open-ended survey responses, evaluators may better understand the multiple sources of program attribution and the weight of various decision makers for complex projects. In these instances, evaluators may include a historical tracing approach to add consideration of the multiple decision maker perspectives. Because the process of gathering the appropriate documentation from program teams, implementers, and customers can be burdensome on all parties involved, evaluators should prioritize projects within a given program that would most affect the confidence of the savings-weighted NTG estimate.

2.3 Spillover-Specific Issues

Some issues related to spillover are applicable for both residential and non-residential programs and are discussed in this section.

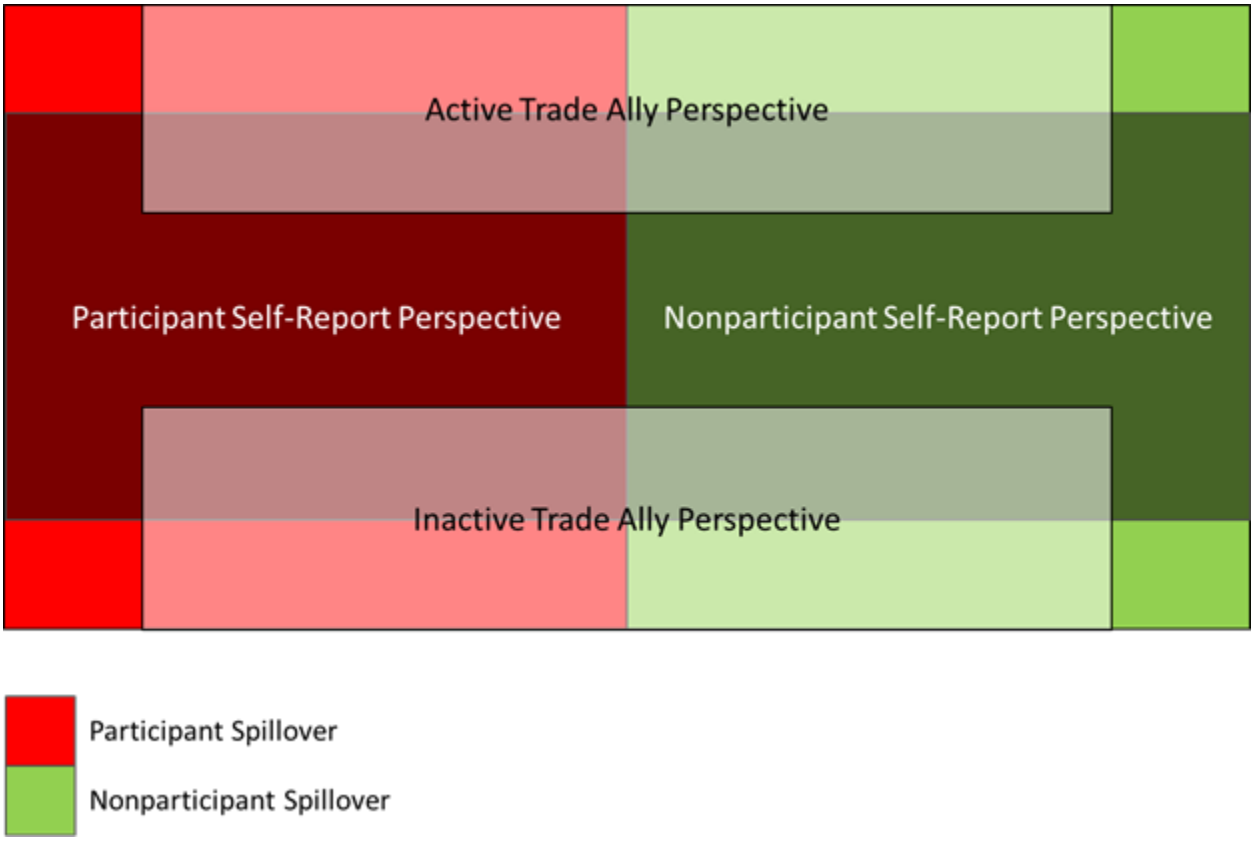
Spillover is generally categorized into two broad categories – participant spillover and nonparticipant spillover (see Table 2-1). These protocols include two general methods of assessing spillover, one through end-user (or participant/nonparticipant) research and the other through trade ally research. Estimates of participant and nonparticipant research are mutually exclusive, as long as only one of these two general methods is used for a given evaluation period. For example, there is no danger of double-counting spillover if an evaluation includes end-user research with both participants and nonparticipants. Similarly, there is no danger of double-counting spillover if an evaluation includes research with both active and inactive trade allies (see definitions in Section 0). However, once end-user research is combined with trade ally research, there is a potential for overlap in the resulting spillover estimates, and care must be taken to avoid double-counting.

Figure 2-1 provides a visual depiction of how the four methods (or "perspectives") for estimating spillover included in these protocols (participant and nonparticipant self-report, Sections 0 and 0; and active and inactive trade ally spillover, Section 0) can be used to assess both participant (red) and nonparticipant spillover (green). This figure illustrates that (a) different spillover methods can overlap in the spillover they cover, leading to potential double-

[58] Violette and Rathbun, *Estimating Net Savings*, 46-48.

counting, and (b) some spillover may not be measured by these methods (as represented by the four corners in the diagram).

Figure 2-1. Example - Types of Spillover and Methods for Assessment



2.3.1 Measure Costs

In order to facilitate analysis of program Total Resource Cost (TRC), estimates of the total incremental measure cost (IMC) at the program level must be developed. IMC values are available for most IL-TRM measures and can be summed to the program level. However, the IMC values for spillover measures could also be estimated and added to this total. The problem is that IMC values for spillover measures can be difficult to estimate. When the magnitude of the savings justifies the effort to estimate the total IMC for spillover measures, the following approaches should be used.

- In cases where the evaluator believes the spillover measure incremental costs are not materially different from the rebated measure incremental costs, the evaluator may multiply the IMC for the rebated measure by the spillover rate to derive the IMC for the spillover measure.
- In cases where the evaluator believes the spillover measure incremental costs are materially different from the installed measure incremental costs (e.g., installation of measures that have no efficiency levels), the evaluator should use the estimated incremental project costs as the IMC for the spillover measure.

Normally, the sample-based estimates of IMCs for spillover measures should be extrapolated to the program level using sample weights. Then the total IMCs for rebated measures and the total IMCs for spillover measures should be summed and used in the TRC calculation.

For measures characterized by the IL-TRM, measure effective useful life (EUL) estimates should be based on the IL-TRM. For measures not characterized by the IL-TRM, evaluator can use either the EUL for similar measures or best professional judgment. In either case, the evaluator must provide the rationale for their choices.

3 Commercial, Industrial, and Public Sector Protocols

The table below lists Illinois non-residential programs and the free ridership protocol and Timing Adjustment time period applicable to each program.[59] The Timing Adjustment time period varies from 2 to 3 years, where programs that include more expensive of larger measures generally rely on a longer time period. If the design of a given program changes significantly, then it may mean that the NTG protocol listed for that program in this document is no longer appropriate. Further, the recommended time period to be applied in the Timing Adjustment may be inappropriate if, for example, the measure mix of the program changes or the research approach followed facilitates a measure-level application of the timing adjustment. In either case, the evaluator should follow the procedures outlined in Section 1.4: Diverging from the IL-NTG Methods. Note that the Core Non-Residential Spillover protocol described in Section 0 is generally applicable to most of these programs.

Table 3-1. Commercial, Industrial, and Public Sector Programs

Program Administrator	Program Name	Timing Adjustment Formula	Free Ridership Protocol
Ameren Illinois	Custom Initiative	3 Year	3.1 Core Non-Residential Protocol
Ameren Illinois	Midstream Initiative	2-3 Year	5.4 Midstream Protocol
Ameren Illinois	Retro-Commissioning Initiative	2 Year	3.4 Study-Based Protocol
Ameren Illinois	Small Business Initiative	2 Year	3.1 Core Non-Residential Protocol
Ameren Illinois	Standard Initiative	3 Year	3.1 Core Non-Residential Protocol
Ameren Illinois	Streetlighting Initiative	3 Year	3.1 Core Non-Residential Protocol
ComEd	Assessments	3 Year	3.4 Study-Based Protocol
ComEd	Behavior – Bus/Pub	3 Year	3.4 Study-Based Protocol
ComEd	Incentives	3 Year	3.1 Core Non-Residential Protocol
ComEd	Midstream/Upstream	2-3 Year	5.4 Midstream Protocol
ComEd	Multifamily (Market rate, common area perspective)	3 Year	3.1 Core Non-Residential Protocol
ComEd	New Construction – Bus/Pub	3 Year	3.3 C&I New Construction Protocol
ComEd	Small Business	2 Year	3.1 Core Non-Residential Protocol
ComEd	Small Business (Small Business Kits component)	2 Year	4.7 Energy Saving Kits and Elementary Education Protocol
ComEd	Streetlighting Initiative	3 Year	3.1 Core Non-Residential Protocol
ComEd	Targeted Systems (RCx, VCx, Industrial Systems)	3 Year	3.4 Study-Based Protocol
Nicor Gas	Business Energy Efficiency Rebates	2 Year	3.1 Core Non-Residential Protocol
Nicor Gas	Business Optimization	2 Year	3.1 Core Non-Residential Protocol
Nicor Gas	Combined Heat and Power	3 Year	3.1 Core Non-Residential Protocol
Nicor Gas	Commercial Food Service Midstream	3 Year	5.4 Midstream Protocol
Nicor Gas	Custom Incentives	3 Year	3.1 Core Non-Residential Protocol
Nicor Gas	Multifamily (Market rate, common area perspective)	3 Year	3.1 Core Non-Residential Protocol
Nicor Gas	Non-Residential New Construction	3 Year	3.3 C&I New Construction Protocol
Nicor Gas	Retro Commissioning	2 Year	3.4 Study-Based Protocol

[59] The "Free Ridership Protocol Name" in the second column of the table refers to the numbered sections in this document, e.g., "0 Core Non-Residential Protocol."

Program Administrator	Program Name	Timing Adjustment Formula	Free Ridership Protocol
Nicor Gas	Small Business Program – Incentives/Direct Install/Kits	2 Year	3.1 Core Non-Residential Protocol
Nicor Gas	Strategic Energy Management	3 Year	3.4 Study-Based Protocol
Peoples Gas/ North Shore Gas	C&I and PS Custom and Prescriptive Rebates, Direct Install, Partner Trade Ally, Kits, Small and Midsize Business Custom, Direct Install & Assessment, Kits, Partner Trade Ally, Prescriptive, Multifamily (Market rate, common area perspective)	3 Year, Direct Install and Small Business 2 Year	3.1 Core Non-Residential Protocol
Peoples Gas/ North Shore Gas	C&I and PS Gas Optimization	3 Year	3.4 Study-Based Protocol
Peoples Gas/ North Shore Gas	C&I and PS Retro-Commissioning	3 Year	3.4 Study-Based Protocol
Peoples Gas/ North Shore Gas	C&I and PS Strategic Energy Management	3 Year	3.4 Study-Based Protocol
Peoples Gas/ North Shore Gas	Commercial Food Service Midstream	3 Year	5.4 Midstream Protocol
Peoples Gas/ North Shore Gas	MF Gas Optimization	3 Year	3.4 Study-Based Protocol
Peoples Gas/ North Shore Gas	Non-Residential New Construction	3 Year	3.3 C&I New Construction Protocol

3.1 Core Non-Residential Protocol

3.1.1 Core Non-Residential Free Ridership Protocol

Key considerations and guidelines for estimation of free ridership under this Core Non-Residential Free Ridership (FR) protocol are listed below:

- **Multiple Questions:** Evaluators will use program participant responses to multiple survey questions as inputs to the free ridership calculation algorithm. Evaluators will not use the response to a single question to establish a survey respondent as either a complete free rider or a complete non-free rider.
- **Consistency Checks:** Evaluators should administer survey questions as checks on the consistency of responses associated with a core free ridership assessment methodology. Evaluators may also reference available quantitative and qualitative data, including consistency check data, to perform documented modifications to individual free ridership estimates resulting from the application of a core free ridership assessment methodology.
- **Vendor Recommendations:** Vendor recommendations may be important in the influence of a program on customer decision-making. Vendors include trade allies, contractors, distributors, suppliers, and other market actors involved in the selection and installation of program-incented equipment on behalf of the participant. If program logic supports it, evaluators will include vendor recommendations as a program factor when reminding respondents of program components. In addition, evaluators will consider surveying vendors instead of or in addition to participating customers as part of their overall evaluation approach. Should both vendors and customers be surveyed, Section 5.1 describes an approved method to merge the two perspectives for the purposes of developing a program-level free ridership estimate.

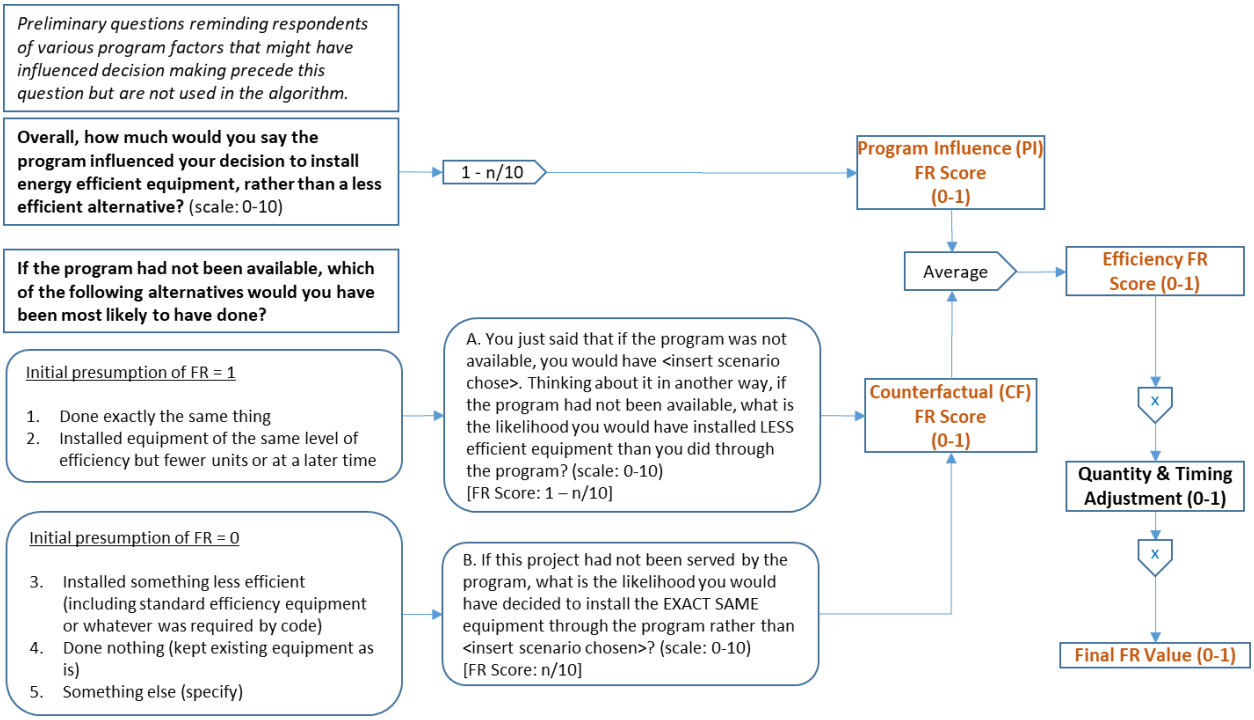
- **Quality Control Review:** For programs involving large, complex projects and decision-making, after all the survey data collection has been completed and preliminary NTGRs have been computed using the standard calculation procedures, a quality control review should be completed. All quantitative and qualitative data should be systematically and independently analyzed by a researcher who is familiar with the program, the individual site and the social science theory that underlies the decision maker survey instrument. This researcher should make an independent determination of whether the additional information justifies modifying the previously calculated NTGR score, and if a modification is determined to be necessary, present any recommended modifications and their rationale in a well-organized manner, along with specific references to the supporting data. Circumstances that may justify a revision of the previously calculated NTGR score include: (1) significant inconsistencies exist between separate FR scores that may lead to elimination of FR scores determined to be outliers; (2) the emerging "story" from the qualitative data is in conflict with the quantitative data, thereby requiring a callback to the customer to resolve the inconsistency and a revision to the original scoring based on the new information; or (3) the entire set of results for an interview are inconsistent, the data are too disparate and would not be helped with a callback. In such cases, a recommendation is made to remove that sample point and replace it with a back-up point (if available).

3.1.1.1 Core Free Ridership Scoring Algorithm

The Core Non-Residential FR protocol consists of two scores that measure the program's impact on efficiency (the Program Influence, or "PI" FR Score and the Counterfactual, or "CF" FR Score), as well as a Quantity and Timing (Q&T) Adjustment that provides credit to the program for increasing the scope of a project or accelerating the timing. The three components are combined as shown in Figure 3-1 to calculate the final free ridership value.

Evaluators will submit participant survey and net savings analysis data to the Illinois NTG Working Group. The group will analyze these data for the purpose of further refining the protocol.

Figure 3-1. Core Free Ridership Algorithm



Program Factors

To ensure that the respondent thinks about the program holistically, the survey will first remind the respondent of program factors that might have influenced decision-making. This could be through one or more questions about program factors or through a read-in of program factors.

The factors referenced in the survey will include those that the evaluator determines could potentially impact the participant decision-making process. Evaluators determine these factors based on available information, including but not limited to discussions with the program management and implementation contractor team, program materials, and program theory or logic model documentation. Program factors may, for instance, include the availability of the program incentive, technical assistance from program partner staff (e.g. trade allies), program staff recommendations, Program Administrator marketing materials, and an endorsement or recommendation by a Program Administrator, account manager or program partner staff.

Evaluators will determine if vendor recommendations should be considered a program factor. This section outlines the rules for the treatment of vendor recommendations.

The evaluator first determines if the program has a qualifying trade ally network. A trade ally network is qualifying if the evaluator determines that the trade ally network meets all of the following criteria:

1. The trade ally network consists of pre-approved, registered trade allies that complete signed agreements or are verified through direct contact with the Program Administrator
2. Registered trade allies are an integral component of program delivery, as supported by program design
3. Registered trade allies receive program-sponsored training

Vendor recommendations are considered a program factor under the following scenario:

- The program has a qualifying trade ally network and the vendor who implemented the project under investigation is currently a registered trade ally, or has been so in the last three years

Vendor recommendations are not considered a program factor under the following scenarios:

- The program does not have a qualifying trade ally network
- The program has a qualifying trade ally network but the vendor who implemented the project under investigation is not a registered trade ally

In cases where vendor recommendations are considered a program factor, the survey shall specifically identify the vendor to the respondent.

Program Influence FR Score

The PI Score measures the overall influence of the program on the participant's decision to select energy efficient equipment instead of a less efficient alternative. It is developed based on a single question that asks the respondent to rate the overall influence of the program on the decision to install energy efficient equipment using a scale from 0 to 10, with 0 being not at all influential and 10 being extremely influential.

Evaluators will calculate the PI Score for each survey respondent using the following equation:

$$Program\ Influence\ FR\ Score\ = 1 - \left(\frac{[Influence\ Rating]}{10}\right).$$

This score can range from 0 (no free ridership) to 1 (full free rider).

In cases where vendor recommendations are considered a program factor, the survey shall ask a second Program Influence question that asks the respondent to rate the influence of interactions with the relevant vendor on the decision to install energy efficient equipment using a scale from 0 to 10, with 0 being not at all influential and 10 being extremely influential. In these cases, the PI Score will be calculated using the maximum influence score across the two questions.

Counterfactual FR Score

The CF Score is based on the most likely action the respondent would have taken with respect to the efficiency of the equipment in the absence of the program.

Evaluators will administer a counterfactual scenario survey question, which asks the respondent to identify which

alternative among a list they would have been most likely to follow if the program had not been available. The scenarios will be specific to the program, but generally include options such as purchasing less efficient equipment, doing the same thing they did through the program, or doing nothing at all. The evaluator should explicitly consider if, before the counterfactual survey question is administered, the respondent needs to be reminded of the program factors. If the position of the counterfactual question relative to the initial introduction of program factors as described in Section 3.1.1.1.1 is such that the respondent might plausibly not recall the definition of the program, the evaluator shall remind the respondent of the program factors (including the vendor recommendations if applicable). The respondents will be asked a follow-up likelihood question as illustrated in Figure 3-1. Evaluators will calculate the CF Score for each survey respondent based on responses to the likelihood follow-up questions using one of the following equations, with the selection of the equation based on the initial scenario selected by the respondent:

$$CF\ Score = \ Likelihood\ would\ have\ done\ less\ efficient\ = \ 1 - \left(\frac{[Rating]}{10}\right)$$

$$OR$$

$$Likelihood\ would\ have\ done\ same\ efficiency\ = \ \left(\frac{[Rating]}{10}\right).$$

Option 2 is an alternative option to be used only in cases where evaluators believe that there is evidence that respondents are not able to understand and correctly answer the likelihood follow-up questions. In Option 2, evaluators will set the CF Score equal to a presumption of FR based on the initial response to the scenario question only. Figure 3-1 provides prescribes initial presumption of FR values for default scenarios. These values are binary and take the form of either no free ridership (CF Score = 0) or total free ridership (CF Score = 1).

If evaluators choose Option 2, they should still report Option 1 scores and provide a rationale for why they believe Option 1 is not appropriate based on available data. Option 2 scores do not need to be reported if Option 1 is chosen, but evaluators may wish to report the scores to enable future dialog in the NTG Working Group as to the form of the Core Non-Residential Free Ridership Protocol.

Both options for calculating the CF Score produce scores that can range from 0 (no free ridership) to 1 (full free rider). Option 2 will lead to CF Score values that are *only* 0 (no free ridership) or 1 (full free ridership).

Quantity and Timing Adjustment

The Q&T Adjustment can reduce the Efficiency FR Score in cases where the program influenced a respondent to expedite all or parts of their project (compared to when they would have completed it without the program). The Q&T Adjustment can range from 0 to 1, where a lower value means a greater FR reduction (i.e., more credit to the program). As shown in Figure 3-1, the Q&T Adjustment is multiplied by the Efficiency FR Score to derive the final FR values.

Quantity adjustments are applicable to equipment measures where 2 or more units are installed, and to all upgrades that have a length or area component (such as air sealing or insulation). When quantity adjustments are applicable, evaluators will first ask respondents how much (in percentage terms) of the installed energy-efficient equipment would have been installed at the same time without the program. Only the quantity that would not have been installed at the same time is eligible to receive the Q&T credit. Evaluators then ask if the respondent would have installed the remaining quantity later and, if so, how much later. When quantity is not applicable, respondents are only asked if they would have installed the equipment later, and if so, how much later.

The timing question will present a series of date ranges (e.g., within one year, between 12 months and 2 years, etc.) and ask the respondent to pick one representing their best estimate of when the measure(s) would have been implemented in the absence of the program. However, program specific timing adjustments have been established, as shown in Figure 3-1, and use the following formulas:

2-year Time Horizon Timing Adjustment = 1 - (Number of Months Expedited - 6)/18

3-year Time Horizon Timing Adjustment = 1 - (Number of Months Expedited - 6)/30

The Timing Adjustment can range from 0 to 1. A smaller value means a greater reduction in FR, because the program

resulted in a greater acceleration of the project. The Q&T Adjustment is then calculated as follows:

*Q&T Adjustment = (% Not Installed at Same Time * Timing Adjustment) + % Installed at Same Time*

Consistency Checks

Per the key considerations listed at the beginning of Section 3.1, respondents should be asked one or more questions to facilitate evaluator understanding of responses to the free ridership questions and potentially reconcile apparently inconsistent responses. Some questions may be asked of all respondents; others may be asked when previous answers appear inconsistent. Evaluators should report on the amount of inconsistency encountered, and on the resolution, to inform future protocol revisions. Four recommended consistency checks are outlined below (three related to the level of efficiency of the equipment and one related to the quantity and timing of the project), but evaluators may also incorporate additional consistency checks as they see fit.

If one or more **efficiency-related inconsistencies** are observed, evaluators will ask a single follow-up question about how the program (including any interactions with the vendor, if applicable) influenced the level of efficiency of the installed equipment. The following inconsistencies trigger the efficiency consistency check:

- **Program Influence FR Score/Counterfactual FR Score Inconsistency**
    1) The difference between the Program Influence FR Score and the Counterfactual FR Score is ≥ 0.4.
- **Vendor Influence FR Score/Counterfactual FR Score Inconsistency**
    1) Vendor recommendations are determined to be a program factor as discussed in Section 0
    2) The difference between the Program Influence FR Score and the Counterfactual FR Score is ≥ 0.4 AND the Program Influence FR Score was calculated based on the vendor-specific Program Influence question.
- **Counterfactual Scenario/Counterfactual Likelihood Inconsistency**
    1) The respondent states that without the program, they most likely would have done exactly the same thing or would have installed equipment of the same efficiency, but fewer units or at a later time, AND the likelihood of installing lower efficiency equipment is > 5.

    OR

    2) The respondent states that without the program, they would have installed lower efficiency equipment, would have done nothing (i.e., kept existing equipment), or would have done something else, AND the likelihood of installing equipment with the same efficiency is > 5.

If a **quantity and timing-related inconsistency** is observed, evaluators will ask respondents to describe how the program (including any interactions with the vendor, if applicable) influenced the timing of their installation or the number of units of equipment they installed (if quantity is applicable). The following inconsistency triggers the quantity and timing consistency check:

- **Counterfactual Scenario/Quantity and Timing Inconsistency**
    1) [*In cases where quantity is applicable*] The respondent states that without the program, they would have installed equipment of the same efficiency but fewer units or at a later time, AND the respondent later states that without the program, they would have installed the same quantity of units at the same time they did (or indicate they are unsure).

    OR

    2) [*In cases where quantity is not applicable*] The respondent states that without the program, they would have installed equipment of the same efficiency but fewer units or at a later time, AND the respondent later states that without the program, they would have completed the project at the same time they

did (or indicate they are unsure).

3.1.1.2 Construction of Core Free Ridership Value

Evaluators will calculate final FR values in the following manner:

Core FR Algorithm = AVERAGE([Program Influence FR Score], [Counterfactual FR Score])*[Quantity & Timing Adjustment]

The Core FR Algorithm is graphically presented in Figure 3-1.

3.2 Core Non-Residential Spillover Protocol

Spillover refers to energy savings associated with energy-efficient equipment installed by consumers who were influenced by an energy efficiency program, but without direct intervention (e.g., financial or technical assistance) from the program.

To place the spillover protocols in context, we begin by defining the NTGR as:

NTGR = (1 – Free Ridership Value + PSO Rate + NPSO Rate)

Where:

PSO Rate = Participant spillover rate

NPSO Rate = Nonparticipant spillover rate

The term (1-Free Ridership) is referred to as the Core NTGR for an efficiency program.

3.2.1 Core Participant Spillover Protocol

The Core Participant Spillover protocol is generally applicable to most commercial, industrial, and public sector programs.

3.2.1.1 Research Methods

Data collection approach. An initial determination of participant spillover may be made based on self-reported findings from surveys of program participants. At a minimum, surveys collecting data pertaining to participant spillover will obtain general information on the specific measures installed and information substantiating their attribution to an energy efficiency program. Research on the specific characteristics of the energy efficient equipment installed and the baseline and operating conditions needed to estimate savings may be done in one of two ways: 1) a detailed battery of measure specific questions may be administered as part of the initial survey; or 2) a separate in-depth follow-up interview may be conducted by the engineer or analyst responsible for the energy savings calculation. In either case, an engineer or analyst will use the collected data to develop an estimate of spillover savings for each project.

Sample Frame. One target for participant spillover research may be the most recent year's program participants who have been sampled for free ridership or process surveys. In the case where a stand-alone spillover study is being conducted, the sample frame may be broader and include those whose participation occurred during the time period of two prior program years.

Because evaluated spillover energy impacts associated with the sample are being extrapolated to the program population, it is important that the sample frame be limited to participating customers for which spillover may potentially be claimed.

Sample frames should be constructed in accordance with the following guidelines:

- Self-directing customers as defined by 220 ILCS 5/8-104(m) should be excluded from the sample frame for natural gas spillover.
- Customers of municipal electric utilities should be excluded from the sample frame for electric spillover.

Timing of Data Collection. Evaluators may either administer the participant spillover module as part of a

comprehensive net-to-gross survey, or they may elect to implement it separately. A follow-up in-depth interview may also be conducted by an engineer or analyst to obtain additional details needed to quantify savings. Optimally, the spillover inquiry should be timed in order to allow sufficient time for spillover to occur; at a minimum, three months after the program-incented measure is installed. Projects installed up to two years after program participation occurred may be counted as spillover, provided it can be substantiated.

3.2.1.2 Approach for Identifying and Quantifying Spillover

Attribution Criteria. Program attribution is determined by the responses to the following two survey questions:

1. How important was your experience in the <PROGRAM> in your decision to implement this measure, using a scale of 0 to 10, where 0 is not at all important and 10 is extremely important?
2. If you had not participated in the <PROGRAM>, how likely is it that your organization would still have implemented this measure, using a 0 to 10 scale, where 0 means you definitely WOULD NOT have implemented this measure and 10 means you definitely WOULD have implemented this measure?

The response to the first question cited above is "Measure Attribution Score 1," and the response to the second question cited above is "Measure Attribution Score 2."

There are two methods by which the attribution may be calculated:

1. Program attribution is established if the average of Measure Attribution Score 1 and (10 – Measure Attribution Score 2) exceeds 5.0[60]; either the Measure Attribution Score 1 or (10 – Measure Attribution Score 2) could be below 5.0—as long as the average is greater than 5.0, the threshold is met. If the average is greater than 5.0, 100% of the measure energy savings referenced in the question are considered to be attributable to the program. If the average is not greater than 5.0, none of the measure energy savings are considered to be attributable to the program.
2. An attribution rate may be calculated as equal to the sum of Measure Attribution Score 1 and (10 – Measure Attribution Score 2), divided by 20. For instance, if the attribution rate is 0.3, then 30% of the measure energy savings referenced in the question are considered to be attributable to the program.

Program attribution option 2 must be used in cases in which evaluators have performed the data collection and analysis required to attribute energy savings using option 2 identified above.

Calculation of Spillover Measure Energy Savings. Energy savings of spillover measures shall be calculated in one of two ways.

1. Those addressed in the IL-TRM shall be calculated in accordance with the methods and algorithms specified in the IL-TRM, and shall reference the IL-TRM-defined time-of-sale or new construction baseline.
2. For measures not addressed in the IL-TRM, evaluators shall quantify savings using accepted industry-wide savings methods that conform to IPMVP or other industry protocols and documents.

Evaluators will make every effort to ensure that there is no double-counting of participant spillover energy savings across multiple sources of participant and nonparticipant spillover (such as participating customer and trade ally surveys) and will document that effort.

Measure implementation must have occurred within one year of the participant spillover study data collection effort in order to be countable as participant spillover.

For the purposes of accounting for spillover savings attributable to a program, spillover will only be quantified for measures implemented within the Program Administrator's service territory.

[60] Note that the threshold value for counting spillover has been lowered from 7.0 to 5.0. The rationale for this lower threshold is: (1) the value of >5 is a strong indicator of program influence on the decision to install non-rebated equipment and is currently being used in other states (e.g., California); (2) the previous value of >7 set an unreasonably high standard for demonstrating program influence on the decision to install non-rebated equipment; and (3) past IL evaluation data show that a threshold of >5 will improve spillover estimates as it provides a better approximation of partial spillover (i.e., where a portion of the savings for each measure installed outside the program gets credited as spillover based upon the program influence rating).

3.2.1.3 Key Participant Spillover Survey Questions

The Participant Spillover question module is designed to be a general inquiry that seeks to: (1) assess whether additional energy efficiency improvements were implemented since the rebated project was completed; (2) confirm that these measures either had not received program incentives, or that there were no plans to submit them for program incentives in the future; (3) gather basic information about the additional energy efficiency measures (e.g., their type, size, quantities, and energy efficiency rating); and (4) establish program attribution.

The basic question structure is shown below. The measure-specific questions can be repeated in order to capture multiple measures. Note that there is considerable flexibility to tailor the questions to specific types of applications and programs.

1. Since your participation in the <PROGRAM>, did you implement any ADDITIONAL energy efficiency improvements at this facility or at your other facilities within <PROGRAM ADMINISTRATOR>'s service territory that did NOT receive incentives through <PROGRAM>?
2. What measures did you implement without an incentive?

MEASURE-SPECIFIC QUESTIONS [repeated for each spillover measure][61]

1. How important was your experience in the <PROGRAM> in your decision to implement this <MEASUREX>? Please use a scale of 0 to 10, where 0 is not at all important and 10 is extremely important.
2. Can you explain how your experience with the <PROGRAM> influenced your decision to install this additional high-efficiency measure?
3. If you had not participated in the <PROGRAM>, how likely is it that your organization would still have implemented <MEASURE>? Please use a 0 to 10, scale where 0 means you definitely WOULD NOT have implemented this measure and 10 means you definitely WOULD have implemented this measure.
4. How many of <MEASURE> did you install?3
5. Questions to further define the measure (as applicable):
   a. Type
   b. Efficiency
   c. Size
   d. Other attributes
6. Can you briefly explain why you decided to install this energy efficiency measure on your own, rather than going through the <PROGRAM>?

Since spillover is best conceptualized as a program-level concept, the preferred approach is to ask the influence questions (Q.1-3 above) relative to the participant's experience with the *program*, rather than relative to the participant's experience with a specific *project* or *incented measure* (in cases where a unique participant implemented more than one project/measure through the program during the evaluation period).

3.2.1.4 Reporting of Results

Evaluators will report the following information relating to participant spillover data collection and analysis in annual EM&V reporting: 1) the number of participants surveyed; 2) the number of survey respondents reporting additional energy efficiency improvements; 3) the number of survey respondents who meet the spillover attribution threshold; 4) the number of respondents for which spillover savings were actually quantified; 5) the spillover savings for each respondent and overall; and 6) the spillover rate. The term (1-Free Ridership) is referred to as the Core NTGR.

The report summarizing spillover should also describe the means by which the participant spillover rate is calculated.

The preferred approach is to estimate program spillover effects by summing spillover estimates for the sample and dividing this sum by the total ex ante or ex post (if available) gross savings for all projects completed by the respondents in the sample to produce the participant spillover rate. This participant spillover rate can be added to

[61] Example questions to gather engineering information to support the calculation of spillover savings may be accessed here: http://www.ilsag.info/il_ntg_methods.html

the Core NTGR for the sample to yield the NTGR. If the sample is stratified, sampling weights must be applied before applying the NTGR to the ex post gross savings of the participant population.

Using this approach, the participant spillover rate is calculated using the following formula:

$$Participant\ Spillover\ Rate = \frac{ISO + OSO\ in\ sample}{Ex\ Post\ Gross\ Impacts\ for\ all\ projects\ by\ respondents\ in\ sample}$$

Where:

ISO = Inside participant spillover

OSO = Outside participant spillover

An alternative method is to add the participant spillover rate to each project's Core NTGR. The project-level NTGRs are then weighted by each project's ex ante or ex post (if available) gross savings as a share of the total. This savings-weighted NTGR can then be applied to the ex post gross savings of the participant population. If the sample is stratified, sampling weights must be applied before applying the NTGR to the ex post gross savings of the participant population. If this method is chosen, the influence questions (Q.1-3 above) must be asked relative to the participant's experience with a specific *project* and the following formula is used:

$$Participant\ Spillover\ Rate = \frac{ISO + OSO\ in\ sample}{Ex\ Post\ Gross\ Impacts\ for\ all\ sampled\ projects}$$

Irrespective of the approach used to calculate the participant spillover rate, it is essential that the wording of the influence questions (i.e., whether relative to the participant's experience with the *program* or relative to the participant's experience with a specific *project or incented measure*) match the impacts included in the denominator of the participant spillover rate.

3.2.2 Core Nonparticipant Spillover Protocol

The evaluation may perform research to measure nonparticipant spillover (NPSO). Evaluators will make efforts to ensure that there is no double-counting of energy savings across multiple sources and will document those efforts.

3.2.2.1 Core Nonparticipant Spillover Protocol – Measured from End Users

NPSO for end users is defined as the energy savings that are achieved when a nonparticipant end user—as a result of the influence of a Program Administrator's programs—implements energy efficiency measures *outside* of the Program Administrator's programs.

One option for the evaluator would be to survey nonparticipating customers and estimate spillover savings for any efficient measures installed that respondents are able to attribute to specific Program Administrator programs. However, in many cases, nonparticipants might find it difficult, if not impossible, to reliably attribute any of their installations to the influence of a specific Program Administrator program. If an evaluator suspects that nonresidential nonparticipants will not be able to reliably attribute spillover savings to any particular Program Administrator program, a second option would be to survey nonparticipants and estimate spillover savings from the installation of efficient measures that respondents are able to attribute to their general knowledge of the Program Administrator incentives and information, regardless of the particular program source. These protocols are written assuming that the NPSO for end users will be estimated using this second option.

Note that this protocol does not address estimating spillover for upstream and midstream programs where the end user is assumed to be completely ignorant of any Program Administrator influence. Of course, when considered feasible, evaluators are free to estimate spillover and spillover rates at the program-specific level with the suggested questions presented in Section 3.2.2.1.2 modified appropriately.

Research Methods

Data Collection Approach. An initial determination of spillover may be made based on self-reported findings from surveys of nonparticipants. At a minimum, surveys collecting data pertaining to nonparticipant spillover will obtain general information on the specific measures installed and information substantiating the influence of the Program Administrator on the installation decision. Research on the specific characteristics of the energy efficient equipment

installed and the baseline and operating conditions needed to estimate savings may be done in one of two ways: (1) a detailed battery of measure specific questions may be administered as part of the initial survey, or (2) a separate in-depth follow-up interview may be conducted by the engineer or analyst responsible for the energy savings calculation.[62] Projects installed within the last two years of the nonparticipant spillover study data collection effort may be counted as spillover, provided program attribution and energy savings can be substantiated. In either case, an engineer or analyst will use the collected data to develop an estimate of spillover savings for each project.

Sample Frame. The sample frame for nonparticipant end user spillover research is composed of customers who have not participated in any programs within the last three years. Because evaluated spillover savings associated with the sample are being extrapolated to the nonparticipant population, it is important that the sample frame be limited to nonparticipants for whom spillover may potentially be claimed.

Sample frames should be constructed in accordance with the following guidelines:

- Exempt electric customers as defined by 220 ILCS 5/8-103B(k)(1) should be excluded from the sample frame for electric spillover.
- Self-directing customers as defined by 220 ILCS 5/8-104(m) should be excluded from the sample frame for natural gas spillover.
- Customers of municipal electric utilities should be excluded from the sample frame for electric spillover.

Timing of Data Collection. Evaluators might administer the nonparticipant end user spillover study in parallel with the program impact evaluation, potential study or saturation study research, or at a different time.

Approach for Identifying and Quantifying Spillover

Key Nonparticipant Spillover Survey Questions. The nonparticipant end user spillover question module is designed to be a general inquiry that seeks to: (1) assess whether additional energy efficiency improvements were implemented during the study period; (2) confirm that these measures had not received program incentives and that there were no plans to submit them for program incentives in the future; (3) gather basic information about the additional energy efficiency measure(s), e.g., the type, size, quantities, and energy efficiency rating; and (4) establish the Program Administrator importance ratings. Note that while the example questions can be customized to assess the influence of a specific program in the Program Administrator portfolio, they are currently worded to capture influence of the Program Administrator, regardless of program source.

Below are example questions that might be used in a nonparticipant spillover survey. They are grouped by the following topics:

- **Threshold conditions:** Is there some credible evidence that it was at least possible for the Program Administrator to have influenced the decision to install additional energy efficient measures?
- **Measure description:** Enough information needs to be collected for the measure and its operation to support a credible estimate of savings
- **Attribution:** Is there credible evidence that the Program Administrator had substantial influence on the end user's decision to install the efficient measure outside of any of the programs in the Program Administrator portfolio?

Threshold Conditions. Spillover cases are identified using a threshold approach in which certain minimal conditions must be met for a customer's installation to be considered for spillover. The following are example questions that evaluators may use (individually or in combination) to determine that program administrator influence on the installation is possible:

1. Before installing these measures, did you know that <PROGRAM ADMINISTRATOR> offers energy efficiency programs, incentives, and information to help their business customers make energy efficiency improvements at their facilities?

[62] See http://www.ilsag.info/il_ntg_methods.html for detailed example questions designed to collect information required to estimate spillover savings for a variety of measures.

2. <PROGRAM ADMINISTRATOR> offers incentives for energy efficient equipment upgrades and improvements through its <PORTFOLIO NAME> programs. Before installing these measures, had you heard about the <PORTFOLIO NAME> programs?

If the answer to either question is "yes", then the threshold condition is met.

Measure Description. The interview (either the initial interview or a separate in-depth follow-up interview) can be used to determine the following basic attributes (as applicable) required to support a credible estimate of savings:

1. Type
2. Efficiency
3. Size
4. Other attributes

The named measure(s) must represent equipment that is more energy efficient than either: (1) equipment required by codes or standards; (2) industry-standard practice for certain types of equipment; or (3) for Custom measures, the minimum efficiency equipment available to meet the customer's requirements. For detailed example questions designed to collect engineering information required to estimate spillover savings for a variety of measures, see http://www.ilsag.info/il_ntg_methods.html.

Attribution. The following questions are suggested to assess attribution. These questions should be asked separately for each potential spillover measure:

1. Earlier you mentioned that you knew that <PROGRAM ADMINISTRATOR> offers incentives to customers for installing energy efficient equipment, and also provides information to customers to help them reduce their energy usage. Thinking about all of the reasons you chose to install the energy efficient <MEASURE>, did your knowledge of these incentives and information available through <PROGRAM ADMINISTRATOR> have ANY INFLUENCE on your decision to install <MEASURE>?

ASK IF Q1=YES

2. Using a scale of 0 to 10, where 0 is not at all influential and 10 is extremely influential, how much influence did your knowledge of the incentives and information <PROGRAM ADMINISTRATOR> offers have on your decision to install your energy efficient <MEASURE>?
3. Just to make sure that we understand you correctly, please answer the following hypothetical question. If you had you NOT known about the incentives and information <PROGRAM ADMINISTRATOR> offers, would you still have installed your energy efficient <MEASURE>? Please use a scale of 0 to 10, where 0 means you definitely WOULD NOT have installed your energy efficient <MEASURE> and 10 means you definitely WOULD have done so.

Consistency Checks

Respondents may be asked one or more questions to facilitate understanding and potentially reconcile apparently inconsistent responses. Evaluators should report on the amount of inconsistency encountered and, on the resolution, to inform future protocol revisions.

ASK IF Q2>7 AND Q3>7 OR Q2<3 AND Q3<3

4. In your own words, can you explain HOW your knowledge of the incentives and information <PROGRAM ADMINISTRATOR> offers influenced your decision to purchase or install your energy efficient <MEASURE>?

The evaluation analyst will assess the response to this open ended question and its consistency with the other questions, and, if warranted based on clear additional information, they will adjust the score based on expert judgment. If an inconsistency exists and the open-ended response does not resolve the inconsistency, the respondent will be removed from the calculation. All instances of this occurring should be documented in the final report. Additional consistency checks, triggered and resolved within the survey with additional questions to participants, remain optional.

Nonparticipant End User Spillover Algorithm. The response to question #2 cited above is "Measure Attribution Score 1," and the response to question #3 cited above is "Measure Attribution Score 2."

There are two methods by which the attribution may be calculated:

1. Provided that the open-ended responses do not contradict influence of the Program Administrator, spillover is considered to be attributable to the Program Administrator if the average of the Measure Attribution Score 1 and (10 – Measure Attribution Score 2) exceeds 5.0[63]; either the Measure Attribution Score 1 or (10 – Measure Attribution Score 2) could be below 5.0—as long as the average is greater than 5.0, the threshold is met. If the average is greater than 5.0, 100% of the measure energy savings referenced in the question are considered to be attributable to the Program Administrator. If the average is not greater than 5.0, none of the measure energy savings are considered to be attributable to the Program Administrator.
2. Provided that the open-ended responses do not contradict influence of the Program Administrator, the attribution rate is calculated as equal to the sum of Measure Attribution Score 1 and (10 – Measure Attribution Score 2), divided by 20. For instance, if the attribution rate is 0.3, then 30% of the measure energy savings referenced in the question are considered to be attributable to the Program Administrator.

Calculation of Spillover Measure Energy Savings. Energy savings of spillover measures shall be calculated in one of two ways.

1. Those addressed in the IL-TRM shall be calculated in accordance with the methods and algorithms specified in the IL-TRM, and shall reference the IL-TRM-defined time-of-sale or new construction baseline.
2. For measures not addressed in the IL-TRM, evaluators shall quantify savings using accepted industry-wide savings methods that conform to IPMVP and other industry protocols and documents.

Evaluators will make every effort to ensure that there is no double-counting of nonparticipant spillover energy savings across multiple sources of nonparticipant spillover reporting (such as nonparticipating customer and trade ally surveys) and will document that effort.

Measure implementation must have occurred within the last two years of the nonparticipant spillover study data collection effort in order to be countable as nonparticipant spillover.

For the purposes of accounting for spillover savings attributable to the Program Administrator, spillover will only be quantified for measures implemented within the Program Administrator's service territory.

Reporting of Results

Evaluators will report the following information relating to nonparticipant spillover data collection and analysis in annual EM&V reporting: 1) how the sample frame was defined, 2) the number of customers surveyed; 3) the number of survey respondents reporting spillover; 4) the number of survey respondents who meet the spillover attribution threshold; 5) the number of respondents for which spillover savings were actually quantified; 6) the spillover savings for each project and overall; 7) the nonparticipant spillover rate, and 8) the calculation of the weights used to extrapolate the spillover to the population of nonparticipants from which the sample was drawn.

The EM&V report should also describe the means by which the nonparticipant spillover (NPSO) rate is calculated. For each sampled site, the verified spillover savings should be summed across measures to derive the total end user NPSO for the sampled sites.[64] The estimate of site-level end user NPSO for the entire sample is then extrapolated to the entire nonparticipant population using sampling weights.

There are two options for using the estimated NPSO.

1. Allocate the portfolio-level spillover savings to individual programs in the portfolio based on each program's share of the ex post gross savings. For each program, the spillover rate could then be calculated for each program using the equation below in which the spillover allocated to each program would be the numerator and the ex post program-specific gross savings would be the denominator.

[63] Note that the same 5.0 threshold value is being used for both Participant and Nonparticipant Spillover.

[64] This includes all samples sites including those that reported no spillover savings.

$$Program - Specific\ NPSO\ Rate = \frac{NPSO_{Program-Specific}}{Ex\ Post\ Gross\ Impacts_{Program-Specific}}$$

The spillover-adjusted NTGR for each program could then be used to adjust the Core NTGR for each program before calculating the TRC. In calculating the Program-Specific NPSO Rate, the numerator and denominator must be consistent in terms of the time period of measure implementation/potential implementation. While this time period must be within the last two years, it may be for a period of less than two years.

2. The NPSO Rate is calculated at the Sector level. The estimated energy savings associated with program-attributable spillover measures implemented during the study period by the entire nonparticipant population is divided by the ex post gross impacts for all the nonresidential programs in the portfolio occurring during the study period. The C&I Sector NPSO Rate is calculated using the following equation

$$Portfolio\ NPSO\ Rate = \frac{NPSO_{Portfolio}}{Ex\ Post\ Gross\ Impacts_{Portfolio}}$$

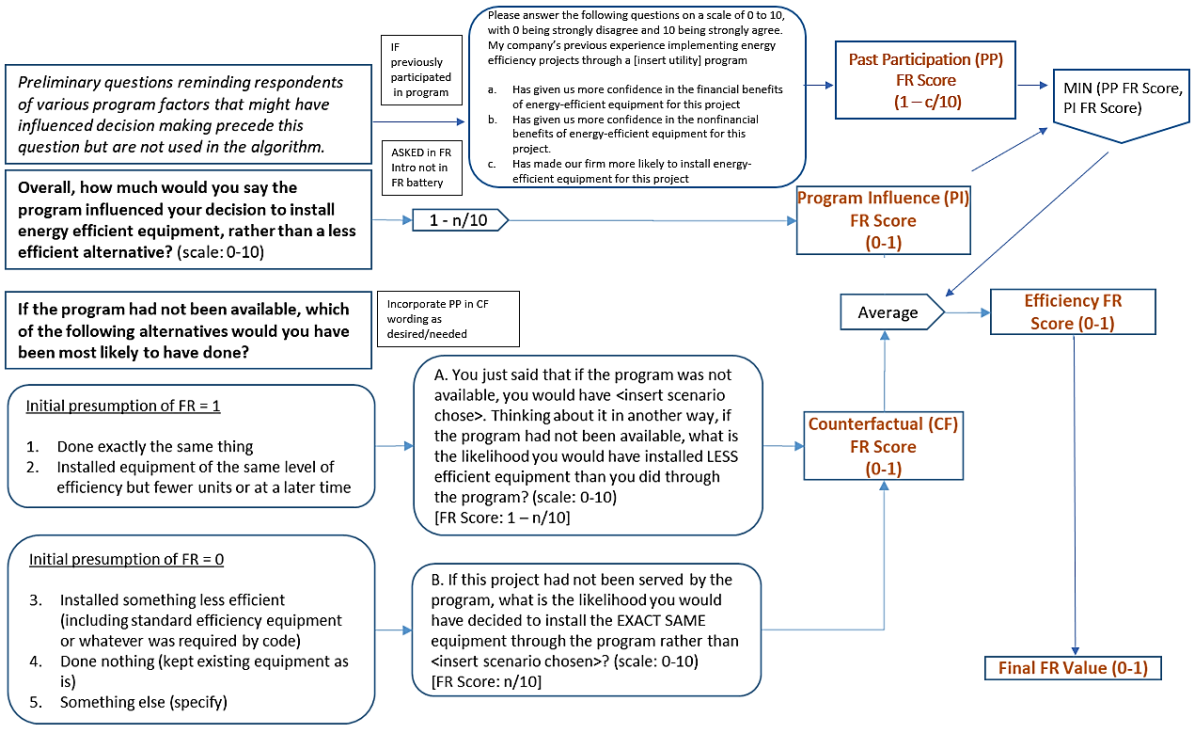
The NPSO rate could then be used to adjust the portfolio core NTGR before calculating the portfolio TRC. Again, in calculating the Portfolio NPSO Rate, the numerator and denominator must be consistent in terms of the time period of measure implementation/potential implementation. While this time period must be within the last two years, it may be for a period of less than two years.

3.3 C&I New Construction Protocol

3.3.1 Free Ridership

The FR algorithm for non-residential new construction programs will generally follow the Core Non-Residential FR protocol, with a few exceptions as illustrated in Figure 3-2. First, the algorithm includes a direct accounting of past participation for respondents who confirm having previously participated in the New Construction program. Second, the counterfactual scale question will accommodate responses at a sub-project level (e.g., at a measure or end use level of granularity). Third, there is no timing adjustment factor.

Figure 3-2. C&I New Construction Protocol



Prior Participation

Respondents will confirm prior participation early in the survey or interview. For prior participants, evaluators should ask participants to what extent they agree or disagree (using a scale of 0 to 10, with 0 being "strongly disagree" and 10 being "strongly agree") with the fact that their previous experience implementing energy efficiency projects through the New Construction program:

a. Has given them more confidence in the financial benefits of energy-efficient equipment for the project in question;
b. Has given them more confidence in the nonfinancial benefits of energy-efficient equipment for the project in question; and
c. Has made their company more likely to install energy-efficient equipment for the project in question.

The Past Participation (PP) FR Score will be developed based on a participant's responses to question (c) above (i.e., whether their company was more likely to install energy-efficient equipment for the particular project due to their previous experience with the program). Evaluators will calculate the PP FR Score using the following formula:

$$Past\ Participation\ (PP)\ FR\ Score = 1 - \frac{PP(c)}{10}$$

This score can range from 0 (no free ridership) to 1 (full free rider). For prior participants, evaluators will use the minimum FR score between the PI FR Score and the PP FR Score for that project. For those who have not previously participated in the program, the PI FR Score will be used (similar to the core algorithm).

Counterfactual Granularity

The development of the Counterfactual FR Score for C&I New Construction projects cannot be implemented at the project level due to these projects generally including multiple components with different decision-making. As such, evaluators should allow respondents to provide answers (and scores) to the counterfactual follow-up questions **at the measure or end-use level**. As such, these counterfactual follow-up questions will allow for partial effects. The counterfactual scenario question can still be asked at the overall project level, and it should remind respondents to consider their past participation in the program as needed/applicable.

Timing Adjustment

Finally, the concept of project timing and deferred free ridership is not applicable to new construction projects.[65] As a result, the timing adjustment detailed in Section 3.1.1.1. will not be included in the free ridership estimation for new construction projects.

3.4 Study-Based Protocol

3.4.1 Free Ridership

The FR algorithm for non-residential study-based programs (See Figure 3-4) will follow the Core Non-Residential FR protocol, with the following exceptions:

Quantity adjustments are not applicable in the Q&T Adjustment.

- The scenario questions used to develop the Counterfactual FR Score in the Core Non-Residential FR protocol will be preceded by questions to determine the familiarity of upgrades found through the study and ability to address them absent the program, as illustrated below in questions Q1 – Q3b.[66]
- Q.1 A 0-10 scale question about the likelihood that the participant would have conducted the study absent the program will be included when the study is the incented service (i.e., RCx, IS), but not for pay for performance programs (i.e., VCx).

At the measure-group level, the following should be included:

[66] It should be noted that the question numbering in Figure 3-5 and Figure 3-6 is for reference purposes only; the additional questions do not have to immediately precede the counterfactual likelihood question.

- Q.2a A yes/no question to determine if the participant performs regular maintenance on the equipment treated through the program
- Q.2b If the response to Q.2a is "yes," a yes/no question to determine if the maintenance always includes the treatment provided through the program
- Q.3a A yes/no question to determine if the participant had prior awareness of the performance issues identified through the study
- Q.3b A 0-10 scale question about the participant's level of familiarity with the recommended actions to rectify the performance issue.

The scenario question will be asked at the measure-group level. Measure-group level responses will be aggregated to the project level, using savings-based weights.

There will be two options for developing the Counterfactual FR Score:[67]

1. The measure-group level Counterfactual FR Score will be developed following Algorithm 1 of the Core Non-Residential FR approach, using responses to the scenario question.
2. The measure-group level No-Program FR Scores will be assigned, based on responses to Q.1, Q.2b, Q.3a, and Q.3b, as follows:
    a. If Q.2b = Yes, then Counterfactual FR Score = 1. This assumes that if the participant performs regular maintenance on the treated equipment and that maintenance always includes the issue addressed through the program, then the participant is a full free rider for that measure group for purposes of calculating the Counterfactual FR Score.
    b. If Q.3a = No and Q.1 = 0 and Q.2b ≠ Yes, then Counterfactual FR Score = 0. This assumes that if the participant was not aware of the performance issue and had a zero likelihood of performing the study absent the program and their maintenance practices do not always include the issue addressed through the program, then the participant is not a free rider for that measure group for purposes of calculating the Counterfactual FR Score since they would not have found out about the issue absent the program.
    c. If Q.3b = 0 and Q.1 = 0 and Q.2b ≠ Yes, then Counterfactual FR Score = 0. This assumes that if the participant had no familiarity with how to rectify the performance issue, had a zero likelihood of performing the study absent the program, and their maintenance practices do not always include the issue addressed through the program, then the participant is not a free rider for that measure group for purposes of calculating the Counterfactual FR Score since they would not have known how to address the issue absent the program.
    d. For all other combinations of responses to Q.1, Q.2b, Q.3a, and Q.3b, the measure-group level Counterfactual FR Scores will be developed following the Core FR approach, using responses to the scenario question.

[67] Option 1 shall be used in all cases for Virtual Commissioning™ programs.

Figure 3-3. Study-Based Free Ridership—Overview

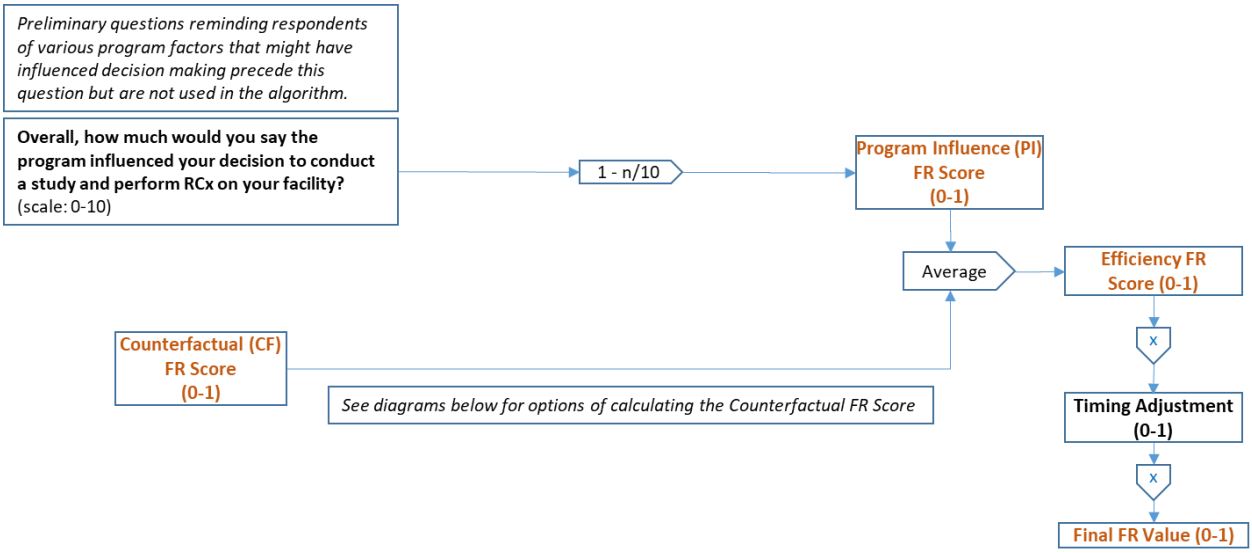


Figure 3-4. Study-Based Free Ridership—No-Program FR Score Option #1

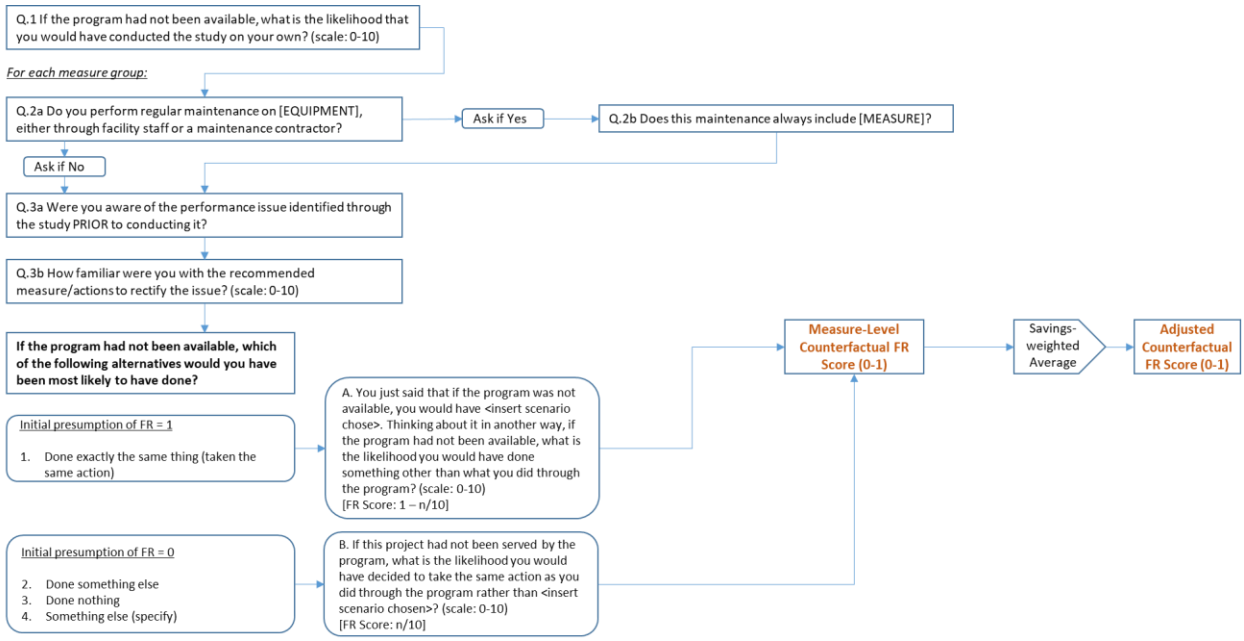

Figure 3-5. Study-Based Free Ridership—No-Program FR Score Option #2

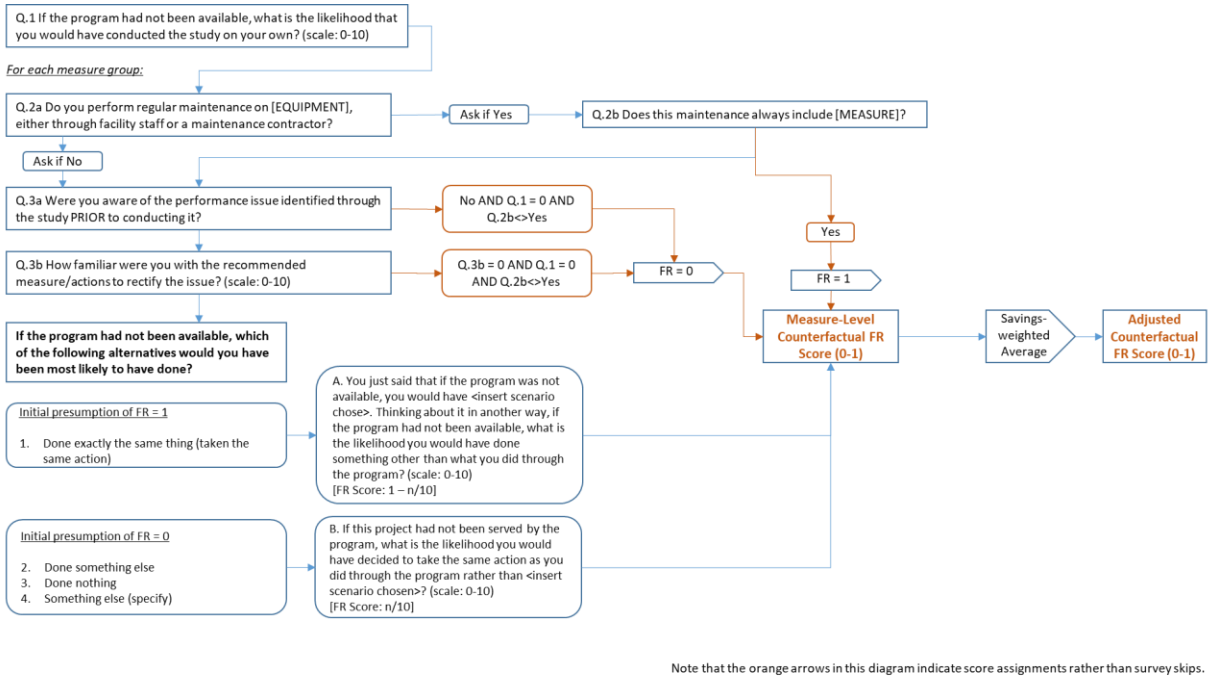


Evaluators will calculate free ridership values for study-based programs as follows:

FR = AVERAGE([Program Influence FR Score], [Counterfactual FR Score])*[Quantity & Timing Adjustment]

Evaluators will develop estimates of free ridership based on the two Counterfactual FR Score options outlined above. Evaluators will select one of these for purposes of calculating the annual incremental energy savings for comparing to the legislated goal. Evaluators will present the results of both estimates of free ridership in EM&V reporting.

3.5 Technical Assistance Protocol

This protocol is applicable to programs that provide technical assistance to encourage the adoption of energy efficiency measures in non-residential facilities, but do not provide financial incentives.

Program-attributable savings from Technical Assistance programs are achieved when a program participant—as a result of the program's influence via the training or technical assistance provided—undertakes energy efficiency improvements on their own, without any direct financial assistance from any other Illinois energy efficiency program.

An initial determination of program-attributable savings is made based on self-reported findings from surveys of program participants. At a minimum, surveys collecting data pertaining to participant measure implementation will obtain general information on the specific measures installed and information substantiating their attribution to the program. Research on the specific characteristics of the energy-efficient equipment installed and the baseline and operating conditions needed to estimate savings may be done in one of two ways: 1) a detailed battery of measure specific questions may be administered as part of the initial survey; or 2) a separate in-depth follow-up interview may be conducted by the engineer or analyst responsible for the energy savings calculation. These collected data may be augmented by detailed facility and measure characteristics if provided by program staff.

3.5.1 Free Ridership

- The FR algorithm for Technical Assistance programs is identical to the Core Non-Residential FR protocol, with the following exception:
    - Key program factors differ extensively from conventional programs and therefore, are described in some detail here. Examples of Technical Assistance program factors that may be included are:
        - Documentation in a program-provided technical report of the energy saving

opportunities from installing the measure.

- Verbal information or guidance provided by a program representative or energy auditor during a training course or an on-site visit.
- A follow-up communication from the utility regarding implementing the recommendations provided through the audit, training, or technical assistance.

Examples of items that would not be considered Technical Assistance program factors are:

- Information from trade shows, conferences, or other professional gatherings
- Recommendation from an equipment vendor that sold you the measure and/or installed it
- Previous experience with the measure
- A recommendation from a design or consulting engineer
- Standard practice in your business/industry
- Corporate policy or guidelines
- Payback on the investment

4 Residential and Low Income Sector Protocols

The table below lists Illinois residential programs and the NTG protocol applicable to each program.[68] If the design of a given program changes significantly, then it may mean that the NTG protocol listed for that program in this document is no longer appropriate. If that happens, the evaluator should follow the procedures outlined in Section 1.4: Diverging from the IL-NTG Methods.

Table 4-1. Residential and Low Income Programs

Program Administrator	Free Ridership Protocol	Program Name
Ameren Illinois	0 4.2 Appliance Recycling Protocol	Appliance Recycling Initiative
	0 4.3 Residential Upstream Lighting Protocol	Retail Products Initiative – Lighting Products
	0 4.5 Prescriptive Rebate (With No Audit) Protocol	Retail Products Initiative – Non-Lighting Products Retail Products Initiative - Efficient Choice Tool*
	4.5 Single-Family Home Energy Audit Protocol	Market Rate Single Family Initiative – Home Efficiency
	0 4.7 Multifamily Protocol	Market Rate Multifamily Initiative
	0 5.3 Consumption Data Analysis Protocol	Behavior Modification
	5.4 Midstream Protocol	Market Rate Single Family Initiative – Midstream HVAC Channel
	†	Retail Products Initiative – Income Qualified Products Income Qualified Initiative Public Housing Initiative Direct Distribution of Efficient Products Initiative
ComEd	0 4.3 Residential Upstream Lighting Protocol and 5.4 Midstream Protocol	Retail/Online (mid- and up-stream measures)
	0 4.5 Prescriptive Rebate (With No Audit) Protocol	Retail/Online (end-user rebated measures) Contractor/Midstream Rebates (end-user rebated measures)Appliance Rebates Heating and Cooling Rebates Weatherization Rebates Efficient Choice*
	4.6 Single-Family Home Energy Audit Protocol	Single-Family Upgrades (market rate component)
	0 4.7 Multifamily Protocol	Multifamily Upgrades (in-unit perspective, market rate component)
	0 4.8 Energy Saving Kits and Elementary Education Protocol	Product Distribution (market rate component)
	5.3 Consumption Data Analysis Protocol	Behavior – Res/IE
	5.4 Midstream Protocol	Contractor/Midstream Rebates (mid- and up-stream measures)
	Attachment C Market Transformation	Electric Homes New Construction
	†	Retail/Online (income eligible component) Product Distribution (income eligible component)

[68] The "Free Ridership Protocol Name" in the second column of the table refers to the numbered sections in this document, e.g., "0 4.7 Multifamily Protocol."

Program Administrator	Free Ridership Protocol	Program Name
		Single-Family Upgrades (income eligible component) Multifamily Upgrades (income eligible component) New Construction – IE Third Party – IE
Nicor Gas	0 4.5 Prescriptive Rebate (With No Audit) Protocol	Home Energy Efficiency Rebates (Single Family)
	4.6 Single-Family Home Energy Audit Protocol	Home Energy Savings (Single Family Assessment/ Direct Install)
		Weatherization (Wx) Prescriptive (Air/Duct Sealing and Insulation)
	0 4.7 Multifamily Protocol	Multi-Family (Assessment/ Direct Install /Direct Distribution) Multi-Family Prescriptive Rebates Central Plant Optimization
	0 4.8 Energy Saving Kits and Elementary Education Protocol	Elementary Education Kits Energy Saving Kits Home Energy Savings/Assessment Leave-Behind Kit
	0 4.9 Residential New Construction Protocol	Residential New Construction
	†	Income Qualified/Eligible Programs
	0 5.3 Consumption Data Analysis Protocol	Behavioral Energy Savings, Advanced Thermostats, Air Sealing with Attic Insulation
	5.2 Code Compliance Protocol	Code Compliance
Peoples Gas/ North Shore Gas	0 4.5 Prescriptive Rebate (With No Audit) Protocol	Home Energy Rebates
	4.6 Single-Family Home Energy Audit Protocol	Home Energy Jumpstart
	0 4.7 Multifamily Protocol	MF Custom MF Partner Trade Ally MF Prescriptive Multifamily (Direct Install)
	0 4.8 Energy Saving Kits and Elementary Education Protocol	Elementary Energy Education Home Energy Jumpstart Leave-Behind Kit
	†	Income Eligible/Qualified Programs
	0 5.3 Consumption Data Analysis Protocol	Home Energy Reports, Advanced Thermostats, Air Sealing with Attic Insulation
All	5.4 Midstream Protocol	(Midstream Programs)

* Until further discussion and research occurs, evaluator consensus is that using the Prescriptive Rebate (With No Audit) protocol is the most appropriate path to pursue for Efficient Choice. However, given the atypical, non-rebate-based nature of this program, further discussion and research is likely appropriate for this program in coming years.

† The evaluation teams should follow the Policy Manual regarding NTG for Income Eligible programs.

4.1 Residential Cross-Cutting Approaches

The approaches in this section can apply to more than one program type but do not supersede program-specific approaches presented in later sections.

4.1.1 Survey Design Issues

Free ridership questions should be asked near the beginning of a participant survey, before asking satisfaction questions. This should prevent participants from confusing free ridership questions with the satisfaction questions, which could influence free ridership scores. In particular, evaluators have observed that some respondents have interpreted the No Program – Efficiency question to be a satisfaction question, synonymous with, "Do you like this item? Would you purchase this?" Evaluators may add an explanation that this question is not about respondents' satisfaction with the item.

4.1.2 Participant Spillover

Effective program marketing and outreach generates program participation and increases general energy efficiency awareness among customers. Spillover can be calculated using participant survey questions, which ask participants about energy-savings actions they have taken on their own since participating in the program. Questions should be sufficiently specific to ensure energy savings associated with spillover can be reasonably well-quantified. These may include questions about measure types or measures installed, quantities, and efficiency levels. When program implementers provide recommendations to participants and can provide data on the types of recommendations made to specific participants, evaluations should attempt to determine whether participants took the recommended actions outside of the program at sites within the program administrator's service territory; if so, savings from those recommended actions should be attributed to the program.

To reduce the respondent's burden, the survey should first ask participants about the influence the program had on their taking additional energy-saving actions on their own. In particular, the evaluation team should ask two close-ended questions to determine program influence on spillover actions. The two required questions, preceded by an optional open-ended warm-up question, are:

- OPTIONAL: Did the program influence you in any way to make these additional improvements?

1. How important was your participation in the <PROGRAM ADMINISTRATOR'S> program on your making additional energy efficiency improvements on your own? [Scale from 0-10 where 0 is "not at all important" and 10 is "extremely important"]
2. If you had not participated in the <PROGRAM ADMINISTRATOR'S> program, how likely is it that you would still have implemented this measure, using a 0 to 10, scale where 0 means you definitely WOULD NOT have implemented this measure and 10 means you definitely WOULD have implemented this measure?

The response to the first required question cited above is "Measure Attribution Score 1," and the response to the second required question cited above is "Measure Attribution Score 2." The specific measures referenced in the question are considered to be attributable to the program if the "Spillover Score" is greater than 5.0:

$$\textit{Spillover Score} = (\textit{Measure Attribution Score 1} + (10 - \textit{Measure Attribution Score 2}))/2 > 5.0$$

If these conditions are met, the evaluator determines that the specific measures referenced in the question are attributable to the program; otherwise, the evaluator determines that the specific measures referenced in the question are not attributable to the program. The attribution criterion represents a threshold approach, in which energy impacts associated with measures implemented by program participants outside the program are either 100% program-attributable or 0% program-attributable.

For each measure mentioned, customers will be asked how they know the measure is more efficient than other models. If the respondent can identify the measure as ENERGY STAR or name an efficiency level that the evaluator confirms as being above the minimum federal standard, or if they identify a technology that the evaluator can confirm is above the minimum federal standard, it will count towards Participant Spillover.

Finally, depending on the measure type cited by the customer, follow-up questions should ask customers to provide

reasonable information to allow the evaluator to estimate the amount of savings using IL-TRM protocols, such as quantity of appliances or the location and amount of insulation.

To calculate the spillover energy and demand savings for these actions, the appropriate version of the IL-TRM should be used. To develop the spillover rate, the total energy and demand impacts from the sampled participants who installed additional measures due to participation in the program are summed, and this sum is divided by the total verified gross impacts from all participants who took the survey.:

$$Participant\ Spillover\ Rate\ (PSO) = \frac{Sum\ of\ Energy\ or\ Demand\ from\ Additional\ Measures\ Installed}{Sample\ Verified\ Gross\ Energy\ or\ Demand\ Impacts}$$

The equation used to adjust the Core NTGR based on participant spillover is as follows:

$$NTGR = (1 - FR + PSO)$$

4.1.2.1 Data Collection

Respondents should be drawn from a random sample of current or up to one year of previous program participants. Regardless of the participation year, spillover should be measured within the last 12 months (from the survey date), but after previous participation; the tracking database should supply this information.

4.1.2.2 Data Analysis

The following four steps calculate spillover:

1. Calculate total spillover savings for each participant installing an efficient measure not rebated through the program where the Spillover Score is greater than 5.0:

$$\text{Measure Spillover} = \text{Measure Savings} * \text{Number of Units}$$

2. Total savings associated with each program participant to calculate overall participant spillover savings.
3. $$\text{Spillover Percentage Estimate} = \frac{\sum \text{Sample Spillover kWh Savings}}{\text{Sample Evaluated Program kWh Savings}}$$

4.1.3 Nonparticipant Spillover Measured from Customers

The evaluation may perform research to measure nonparticipant spillover (NPSO). If so, care should be taken to ensure spillover is not double-counted with a trade-ally approach. The basic method uses a two-step process: (1) conduct a nonparticipant survey to identify potential spillover measures and (2) if needed, conduct a follow-up call or on-site visit by technical staff to confirm attribution and obtain information needed to estimate energy savings.

4.1.3.1 Basic Method

Sampling

As spillover may be rare in the nonparticipating population, determining spillover will likely require a large sample of customers who have not participated in any energy efficiency programs, including a behavioral program, within the past three years. Customers will be removed from the sample frame if their account numbers can be cross-referenced against a list of program participants from the previous three years. The survey should target household members responsible for paying utility bills. Survey respondents will be asked a screening question (whether they have participated in a program in the past three years) to confirm their household qualifies as a true nonparticipant.

Measure-Specific Questions

Depending on the spillover measure type reported by the customer, follow-up questions should be included to gather sufficient information to reasonably assess the saving amount by applying the IL-TRM, understanding that assumptions must be made if IL-TRM inputs cannot be easily supplied by the participant. Such assumptions should be conservative, or, if not conservative, reasons for deviating from the conservative application should be documented. Measures that cannot be reasonably quantified within available evaluation budgets should be excluded from spillover calculations.

For measures included in the IL-TRM, savings will be assessed using the IL-TRM algorithms. Baselines for measures

not in the IL-TRM will be assessed based on appliance standards and building codes, if applicable, and, if not, through engineering judgements of existing or market conditions. Engineering assumptions and analysis by the evaluator will be applied for measures not included in the IL-TRM. Key assumptions should be documented in the report.

4.1.3.2 Attribution Approach

To receive credit for energy savings, the nonparticipant must fit the following criteria: (1) be familiar with the Program Administrators energy efficiency campaign (e.g., ActOnEnergy for Ameren); and (2) indicate that some aspect of the Program Administrator's energy efficiency programs motivated their purchases. Influence will be measured on a scale of 0 to 10, where 10 is extremely influential and 0 is not at all influential. Savings attribution requires a Spillover Score of greater than 5.0.

Survey respondents will be asked a series of questions following the logic shown in Figure 4-1. First, the customer will indicate whether they know about their Program Administrator's energy efficiency programs and/or marketing messages. If customer is aware, the survey will ask if they or anyone in their household made an energy efficiency improvement within the last year, and if so, what improvements they made. Responses to these questions will generate a list of potential spillover measures (shown at point "[A]" in Figure 4-1). Customers will be asked how they know the measure is more efficient than other models. If the respondent can identify the measure as ENERGY STAR or name an efficiency level that the evaluator confirms as being above the minimum federal standard, or if they identify a technology that the evaluator can confirm is above the minimum federal standard, it will count towards NPSO. At this point in the NPSO process, the customer could be referred for a follow-up call with a technical interviewer.[69]

To assess attribution for each spillover measure mentioned, the customer will be asked questions to be scored in two areas. Spillover may be program-attributable for those measures for which self-report data meet the following threshold condition:

$$Spillover\ Score\ =\ (Attribution\ Score\ 1\ +\ (10\ -\ Attribution\ Score\ 2))/2\ >\ 5.0$$

Attribution Score 1

The first score, "Attribution Score 1," measures the influence level (on a scale of 0 to 10, where 10 is extremely influential and 0 is not at all influential) their Program Administrator had on the purchase of the measure.

Influence can derive from the following:

1. General information about energy efficiency provided by the Program Administrator (e.g. through a bill insert)
2. Information from a contractor or retailer related to the Program Administrator's programs.
3. Word-of-mouth from people installing energy-efficient equipment and receiving a rebate from the Program Administrator.

Attribution Score 1 is the maximum score (or Yes response) assigned to any source of influence from the Program Administrator.

Attribution Score 2

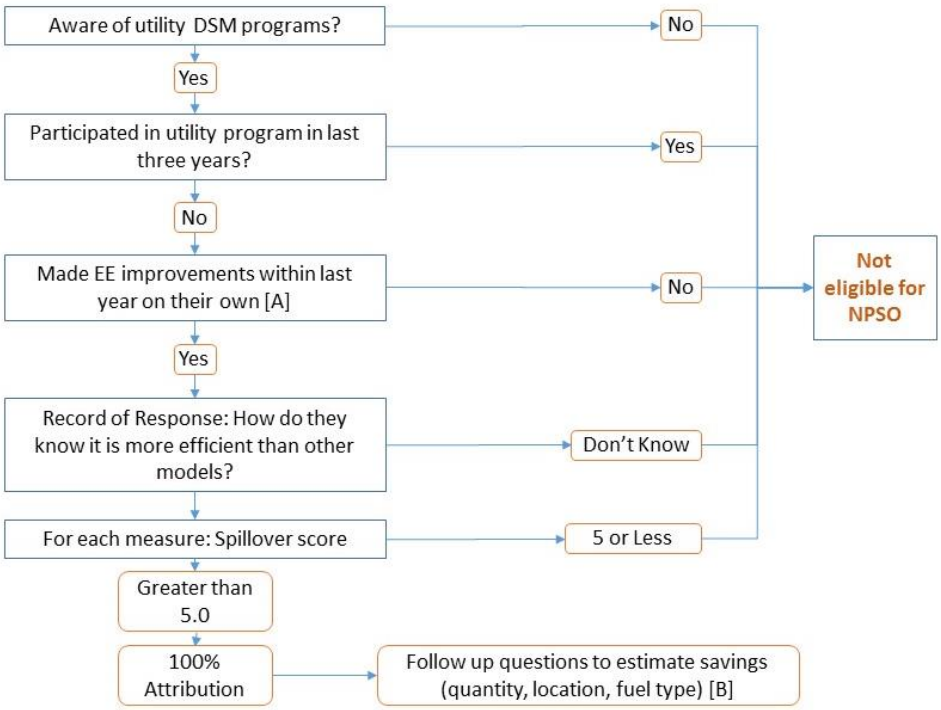
The second score, "Attribution Score 2," comes from the customer's response to a single question to assess the counterfactual, asking about the likelihood (on a scale of 0 to 10, where 10 is extremely likely and 0 is not at all likely) that the customer would have installed the measure had they not been influenced by the program.

The Spillover Score is then the average of the Attribution Score 1 and (10 – Attribution Score 2). If that Spillover Score is greater than 5.0, 100% of the savings are attributed to the Program Administrator for that measure.

Finally, depending on the measure type cited by the customer, follow-up questions will gather information to enable an estimate of savings (shown in the figure as [B]), such as quantity of appliances or the location of insulation.

[69] Customers who installed efficient lighting (CFL/LED) will not be eligible for NPSO if those savings are already claimed by an upstream lighting program. A separate NPSO protocol is provided specifically for upstream lighting programs.

Figure 4-1. NPSO Question Logic



4.1.3.3 Scoring

Survey respondents' answers to the NPSO questions will determine total energy and demand savings attributed to the program. Table 4-2 lists NPSO measures under column A, the Spillover Score under column B, the estimated measure savings under column C, the percentage of allocated savings under column D, and the total allocated savings under column E. Column F shows the calculated average energy savings per spillover measure, determined by dividing the total allocated savings (the sum of column E) by the number of surveyed nonparticipating customers. The table shows how kWh NPSO savings would be calculated; calculations of therm or demand savings would be accomplished in the same manner.

Table 4-2. Estimation of Respondents' NPSO Savings

A	B	C	D	E	F
Spillover Measure	Spillover Score	Measure Savings (kWh)	Allocated Savings	Total kWh Savings	Average kWh Per Surveyed Customer
Measure1	Scale of 0 to 10	Savings1	100% if [B] > 5.0	[C] x [D]	N/A
Measure2	Scale of 0 to 10	Savings2		[C] x [D]	
MeasureN	Scale of 0 to 10	SavingsN	0% if [B] ≤ 5.0	[C] x [D]	
				Sum of column E = Total kWh Savings	Total kWh Savings ÷ Number of Completed Surveys

Table 4-3 shows the process for estimating total NPSO generated by the Program Administrator during the program year (for electric savings). The savings attributed from the survey population will be extrapolated to the nonparticipating residential customer population to determine the overall NPSO savings. Then NPSO energy savings will be converted into a percentage using the total evaluated electric savings for the program year. A similar process would apply for calculating therm or demand NPSO.

Table 4-3. Calculation of Total NPSO Generated

Variable	Description	Source/Calculation
F	Average kWh Energy Savings per Surveyed Customer	Survey data and Savings Calculation
J	Total Nonparticipating Residential Population	Customer database
K	NPSO MWh Energy Savings Extrapolated to Nonparticipating Population	[F × J] ÷ 1,000 kWh/MWh
S	Total Evaluated MWh Savings	Residential Portfolio Savings
G	NPSO Spillover Rate	K ÷ S

4.2 Appliance Recycling Protocol

Appliance recycling programs (ARPs) typically offer some mix of incentives and free pickups for the removal of old but operable refrigerators, freezers, or room air conditioners. These programs encourage consumers to undertake the following:

- Discontinue use of secondary or inefficient appliances;
- Relinquish appliances previously used as primary units upon their replacement (rather than keeping the old appliance as a secondary unit); and
- Prevent the continued use of old appliances in other households through direct transfers (i.e., giving it away or selling it) or indirect transfers (resale in the used appliance market).

As the program theory and logic for appliance recycling differ significantly from standard "downstream" incentive programs (which typically offer rebates for purchases of efficient products), the free ridership estimation approach also significantly differs.

The basic and enhanced methods are described next.

4.2.1 Basic Method

4.2.1.1 Free Ridership

Free ridership is based on participants' anticipated plans had the program not been available, thus classifying a free rider as a participant who would have removed the unit from service regardless of the program.

Estimating net savings for ARPs should adopt a multistep process to segment participants into different groups, each with specific attributable savings.

In general, independent of program intervention, participating appliances would have been subject to one of the following options:

1. The appliance would have been kept by the participating household.
2. The appliance would have been discarded in a way that transfers the unit to another customer for continued use.
3. The appliance would have been discarded in a way that would have permanently removed the unit from service.

Only Option 3 constitutes free ridership (the proportion of units that would have been taken off the grid absent the program). Options 1 and 2 both indicate non-free riders. However, these respondents need to be further classified to account for secondary market impacts, described below.

Data Collection

A participant survey—drawn from a random sample of participants—will serve as the primary source of data collected for estimating NTG for the ARP. To determine the percentage of participants in each of the three options, evaluators will begin by asking surveyed participants about the likely fate of their recycled appliance had it not been decommissioned through the program. Responses provided by participants generally can be categorized as follows:

1. Kept the appliance.
2. Sold the appliance to a private party (either an acquaintance or through a posted advertisement).
3. Sold or gave the appliance to a used-appliance dealer.
4. Gave the appliance to a private party, such as a friend or neighbor.
5. Gave the appliance to a charity organization, such as Goodwill Industries or a church.
6. Had the appliance removed by the dealer from whom the new or replacement appliance was obtained.
7. Hauled the appliance to a landfill or recycling center.
8. Hired someone else to haul the appliance away for junking, dumping, or recycling.

Additional, follow-up questions will be included to validate the viability of all responses.

Next, evaluators will assess whether each participant's final response indicates free ridership:

- Some final responses clearly indicate free ridership, such as: "I would have taken it to the landfill or recycling center myself."
- Other responses clearly indicate no free ridership, as when the appliance would have remained active within the participating home ("I would have kept it and continued to use it") or used elsewhere within the Program Administrator's service territory ("I would have given it to a family member, neighbor, or friend to use").

If the respondent planned to have the unit picked up by the retailer and the retailer would likely resell the unit in the secondary market, they are not a free rider. Absent retailer survey primary research described in the Enhanced Options below, the evaluators will utilize data from the most recent research conducted of the ComEd program to determine the proportion of free riders unless another metric is mutually agreed upon by the evaluators.[70]

Secondary Market Impacts

In the event that the unit would have been transferred to another household (Option 2 above), the question then becomes what purchasing decisions are made by the would-be acquirers of participating units now that these units are unavailable. Such would-be acquirers could:

1. Not purchase/acquire another unit.
2. Purchase/acquire another used unit.

Adjustments to savings based on these factors are referred to as the program's secondary market impacts.

If it is determined that the participant would have directly or indirectly (through a market actor) transferred the unit to another customer on the grid, the next question addresses what that potential acquirer did because that unit was unavailable. There are three possibilities:

A. **None of the would-be acquirers would find another unit.** That is, program participation would result in a one-for-one reduction in the total number of appliances operating on the grid. In this case, the total energy consumption of avoided transfers (participating appliances that otherwise would have been used by another customer) should be credited as savings to the program. This position is consistent with the theory that participating appliances are essentially convenience goods for would-be acquirers. (That is, the potential acquirer would have accepted the appliance had it been readily available, but because the appliance was not a necessity, the potential acquirer would not seek out an alternate unit.)

B. **All of the would-be acquirers would find another unit.** Thus, program participation has no effect on the total number of appliances operating on the grid. This position is consistent with the notion that participating appliances are necessities and that customers will always seek alternative units when participating appliances are unavailable.

[70] Note that such retailer interviews are being conducted annually for the ComEd ARP evaluation, and answers are used directly in the calculation of the NTG ratio in cases where: (1) the respondent planned to have the unit picked up by the retailer; and (2) the retailer was interviewed.

C. **Some of the would-be acquirers would find another unit, while others would not.** This possibility reflects the awareness that some acquirers were in the market for an appliance and would acquire another unit, while others were not (and would only have taken the unit opportunistically).

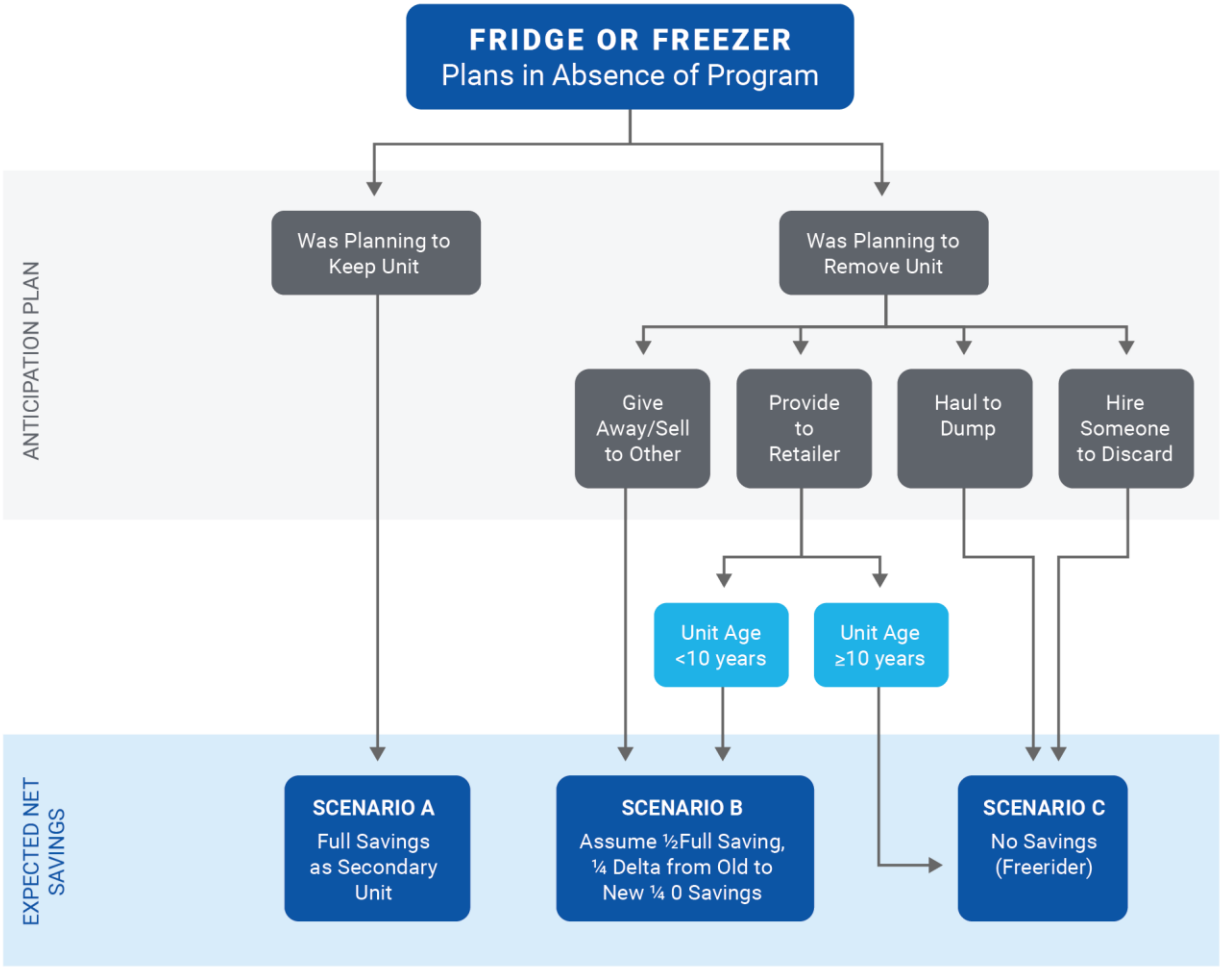
The evaluators will assume Possibility C unless primary research within a Program Administrator's service territory to assess the secondary appliance market is undertaken as described in the Enhanced Options below. Specifically, evaluators will assume that half (0.5, the midpoint of Possibilities A and B) of the would-be acquirers of avoided transfers found an alternate unit.

Once the proportion of would-be acquirers who are assumed to find alternate units is determined, the next question is whether the alternate unit was likely to be another used appliance (similar to those recycled through the program) or, with fewer used appliances presumably available in the market due to program activity, would the customer acquire a new standard-efficiency unit instead.

4.2.1.2 Integrating Free Ridership and Secondary Market Impacts

The flow chart shown in Figure 4-2 illustrates how net savings will be derived for an ARP. As shown, below, expected savings fall into three different scenarios.

Figure 4-2. Appliance Retirement Scenarios



Source: Adapted from the Pennsylvania Statewide Evaluator Common Approach for Measuring Net Savings for Appliance Retirement Programs, Guidance Memo-026, March 14, 2014.

4.2.1.3 Scoring Algorithm

Net savings will be assigned individually to each respondent, based on responses provided to the questions discussed above. Net savings will be averaged across all respondents to calculate program-level net savings. The following equation will be used:

$$FR = (free\ ridership\ and\ secondary\ market\ impacts\ \% - induced\ replacement\ \%)$$

Table 4-4 demonstrates the proportion of a sample population classified into each of the eight potential (Tertiary Classification) categories and the resulting weighted net savings.

Table 4-4. Net Savings Example for a Sample Population*

Primary Classification	Secondary Classification	Tertiary Classification	Population (%)	UEC (kWh) w/out Program	UEC (kWh) w/ Program	kWh Savings
Would have kept unit	Scenario A: Kept No Induced Replacement	N/A	25%	1,026	0	1,026
Would have	Scenario B:	N/A	30%	1,026	520	506

Primary Classification	Secondary Classification	Tertiary Classification	Population (%)	UEC (kWh) w/out Program	UEC (kWh) w/ Program	kWh Savings
removed unit	Transferred No Induced Replacement					
	Scenario C: Removed from Service	Recycled/ Destroyed	20%	0	0	0
		Retailer would Recycle	13%	0	0	0
Net Savings (kWh)						475

*The percent values presented in this table serve only as examples; actual research should be conducted to determine the percentage of units falling into each of these categories. Note that UEC (Unit Energy Consumption) values presented in the table represent example values, factoring in part-use.

4.2.2 Enhanced Method

Results can be enhanced by including three additional research efforts. The basic method has defaults where primary research on enhanced approaches cannot be performed:

1. A retailer survey, to determine the quantity and/or proportion of units returned to a retailer and that the retailer would deconstruct or recycle. Through this survey, one would determine a retailer's criteria for reselling used units vs. deconstructing them, based on unit age and condition. Results from the survey and analysis would be used to determine the proportion of those who would have returned an old appliance to the retailer that should be included in Scenario D (free riders). This research was conducted for ComEd in EPY6 evaluation, and those results were applied to Ameren.
2. An appliance market assessment study to determine the size of the secondary appliance market and whether removal of participating units from the market would cause an otherwise would-be receiver to purchase an alternative used or new unit. Savings attributable to these participants are the most difficult to estimate, as the scenario attempts to estimate what the prospective buyer of a used appliance would do in the absence of finding a program-recycled unit in the marketplace (i.e., the program took the unit off the grid, so the prospective purchaser faced, in theory, a smaller supply of used appliances). It is difficult to answer this question with certainty, absent Program Administrator-specific information regarding the change in the total number of appliances (overall and used appliances specifically) that were active before and after program implementation. In some cases outside of Illinois, evaluators have conducted in-depth market research to estimate both the program's impact on the secondary market and the appropriate attribution of savings for this scenario. Although these studies are imperfect, they can provide Program Administrator-specific information related to the program's net energy impact. Where feasible, evaluators and utilities should design and implement such an approach. Unfortunately, this type of research tends to be cost-prohibitive, or the necessary data may simply be unavailable.
3. However, it is possible to estimate through nonparticipant surveys which of the disposal responses given by nonparticipants were most likely to have been to an opportunistic would-be-acquirer. Transfers that would most likely have been opportunistic are determined primarily based on the cost to the recipient. If the appliance was sold or transferred to a retailer, there would have been a cost to the recipient of that appliance. If the recipient was willing to pay for the appliance or was willing to exert the effort to visit a retail location, this suggests the recipient was actively seeking an appliance. However, if the unit were given away for free, there was little cost to the recipient, and it is a reasonable proxy for the proportion of opportunistic acquirers. This proportion would replace the 50% default assumption (scenario C in Figure 4-2) of would-be-acquirers that would or would not find an alternate unit.
4. A nonparticipant survey can be used to assess how nonparticipants acquire and dispose of used units. As nonparticipants do not have the same perceived response bias as participants, they can help offset some of this potential bias in estimating the true proportion of the population that would have recycled their units in program's absence. The evaluators will average the results of the nonparticipant survey with the participant survey if the nonparticipant survey is of sufficient sample size. Otherwise, results may be used

for a qualitative characterization of potential bias. Though recommended, use of a nonparticipant survey need not be required, given budget and time considerations. A nonparticipant survey was completed as part of ComEd's EPY6 evaluation and used qualitatively to validate participant results.

4.3 Residential Upstream Lighting Protocol

The Illinois Residential Upstream Lighting programs to date have provided discounts on efficient lighting through retailers at the point of purchase. Such programs often remain transparent to customers purchasing incentivized lighting. Program administrators also do not know the identity of most customers purchasing the program-discounted lighting; so these customers cannot easily be contacted once they leave the store for a traditional self-report NTG evaluation survey (i.e., an after-the-fact, direct solicitation of customers regarding what they would have done in the program's absence). Similar surveys can be conducted with customers within program retailers after they have made their lighting purchasing decision but before they leave the store. For programs such as this, in store customer surveys are preferable to the traditional self-report telephone surveys that ask customers to recall their past light bulb purchases. Light bulbs are a small and relatively insignificant purchase for most people, thus the recall bias could be substantial.

Further, as upstream programs work with multiple market actors and can include wide-reaching marketing campaigns promoting energy efficiency to the general public, they tend to stimulate spillover and "market effects." As a result, estimating NTG for upstream residential lighting programs can be challenging. Multiple methods exist, each with their own strengths and weaknesses.

Ameren and ComEd implement their residential lighting programs comparably, and the evaluation teams have used a consistent primary NTG evaluation method. This section details the consensus NTG methodology, which has been used multiple times for both ComEd and Ameren and is considered the most well-vetted and defensible NTG method that has been successfully used in Illinois.

For EPY5 and EPY6, Ameren and ComEd used a customer self-report methodology to estimate NTG for their upstream residential lighting programs.[71] Customer self-report data in this method are collected during surveys conducted within program retailers with customers purchasing program bulbs (i.e., in-store intercept surveys). This method separately estimates free ridership, participant spillover, and nonparticipant spillover. Details follow on the primary data collection and scoring algorithms.

4.3.1 Basic Method

4.3.1.1 Free Ridership

Free ridership for this program is calculated as the proportion of program bulbs that would have been purchased if the program did not exist. Three alternative scenarios could occur:

1. Full Free Rider: The customer would have purchased the same quantity of efficient bulbs (CFLs or LEDs) in the program's absence.
2. Partial Free Rider: The customer would have purchased fewer efficient bulbs (CFLs or LEDs) in the program's absence.
3. Non-Free Rider: The customer would have not purchased any efficient bulbs (CFLs or LEDs) in the program's absence.

Free ridership is calculated as the average of two distinct scores: a Program Influence Score and a No-Program score. These scores are defined as follows:

1. The Program Influence Score captures the maximum level of program influence, reported by a survey respondent, of the residential lighting program on their decisions to purchase program bulbs on the day of the survey. This program influence can take a number of forms, such as: the monetary incentive provided to decrease the cost of high-efficiency bulbs; program-sponsored educational materials that explain the

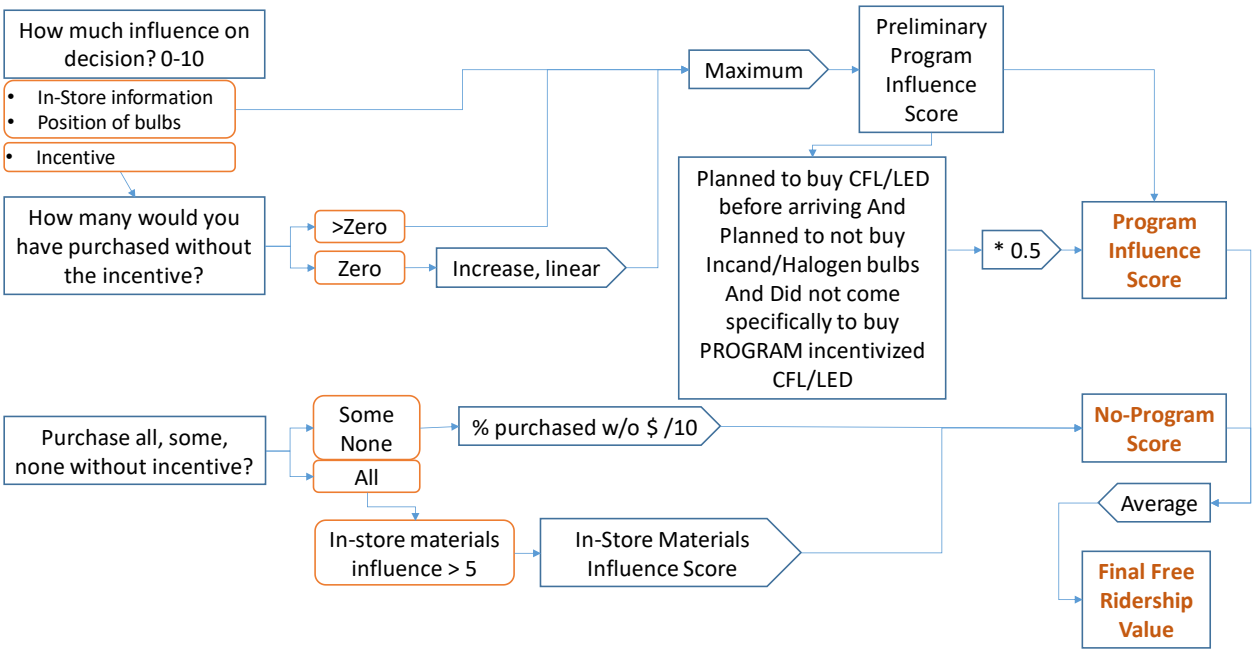
[71] ComEd has used this method since EPY2. Ameren began using it in EPY5.

benefits of efficient lighting; in-store product placement of efficient bulbs; and program bulb recommendations provided by retail store personnel.

2. The No-Program Score is used to estimate how many program bulbs a survey respondent would have purchased in the absence of the residential lighting program.

Figure 4-3 illustrates the scoring algorithm for Residential Upstream Lighting Free Ridership via In-Store Intercepts.

Figure 4-3. Residential Upstream Lighting Free Ridership via In-Store Intercept



4.3.1.2 Data Collection

To estimate free ridership, the evaluation teams will conduct in-store intercept surveys with customers purchasing program-discounted lighting at participating retailers. Customers are asked questions that are used to estimate a Program Influence Score and a No-Program Score for each customer and efficient bulb type purchased.

Primary Program Influence Score Questions

1. Light bulb purchasing plans for current shopping trip (Yes/No)
2. If planning to purchase bulbs:
   a. Bulb type (CFL, LED, Incandescent, Halogen)
   b. Program administrator-incentivized bulbs (Yes/No)
3. Influence of various program factors:
   a. Program incentive
   b. In-store information (printed materials or information from Program Administrator representatives or retail personnel)
   c. Positioning of discounted bulbs within the store

Primary No-Program Score Questions

1. Stated preference of light bulb purchases had the Program Administrator incentive not been available (purchase all, some, or none of efficient bulbs)
2. Quantity of light bulbs purchased absent the incentive

4.3.1.3 Scoring Algorithms

Using the data collected from program participants during the in-store intercept surveys, Program Influence and No-Program Scores are calculated for each survey respondent and then combined to estimate a respondent-specific Free Ridership Score.

Calculation of the Program Influence Score

Survey respondents purchasing one or more program-discounted bulbs are assigned a Preliminary Program Influence Score based on the maximum program influence level (on a 0 to 10 scale) they assigned to one or more program factors (e.g., monetary incentive/informational materials [printed or from store personnel]/product positioning). The influence level assigned to the monetary incentive should be increased for survey respondents (using a linear decreasing function)[72] who indicated that, absent the incentive, they would not have purchased any of the program bulbs they were purchasing that day.

After the Preliminary Program Influence Score is assigned, a secondary algorithm is run that adjusts the preliminary program influence based on survey data regarding the customers purchasing plans when they entered the store. Survey respondents who indicated they planned to purchase high-efficiency bulbs prior to entering the store and who had not come to the store specifically to buy Program Administrator-incentivized program bulbs, should have their Program Influence Score cut in half. This adjustment makes the final Program Influence Score reflective of their stated planned intention to purchase efficient bulbs in the program's absence.

Calculation of the No-Program Score

The No-Program Score is based on whether a respondent states they would have purchased all, some, or none of the program-discounted bulbs in the absence of Program Administrator incentives. Respondents reporting they would have purchased all of the efficient bulbs without the incentive should be considered free riders and receive a No-Program Score of zero. Those reporting they would have purchased none of the efficient bulbs without the incentives should be classified as non-free riders and receive a No-Program Score of 10, the maximum. Respondents reporting they would have purchased some of the efficient bulbs without the incentive should be assigned a No-Program Score between 0 and 10, reflective of the percentage of efficient bulbs they would not have purchased absent the program.

Respondents reporting they would have purchased all of the program-discounted bulbs in the program's absence, but in-store materials provided by the Program Administrator had a moderate to high influence on their decision, should have their No-Program Scores adjusted to equal the level of influence they attributed to these program-sponsored informational materials.

4.3.1.4 Calculation of Free Ridership

The Free Ridership rate is calculated as follows:

$$\text{Free Ridership} = 1 - (\text{Program Influence Score} + \text{No-Program Score})/20$$

Using the calculated Program Influence and No-Program Scores, Free Ridership is calculated as one minus the sum of the two scores (Program Influence Score plus No-Program score), divided by 20. Dividing the sum of scores by 20 results in a ratio (between 0 and 1) that is representative of the average of the two zero to 10 scores. Subtracting this ratio from one reverses the score, thus representing the free ridership level. If either the No-Program or Program Influence Scores are missing, Free Ridership can be calculated using the single available score divided by 10. Evaluators may also reference available data to perform documented modifications to individual free ridership estimates resulting from the application of this free ridership assessment methodology.

[72] The function, adjusted monetary score = (monetary score + 10)/2, increases the monetary score using a decreasing linear function. This function results in an increase in the monetary influence score of between 0 and 5 points depending on their original monetary score (i.e., an original score of 0 would become a 5, a 5 would become a 7.5, and a 10 would remain a 10). In past Illinois evaluations, this adjustment has typically changed less than 10% of all monetary scores.

4.3.2 Participant Spillover

For this program, participant spillover results from purchases of non-discounted efficient bulbs by program bulb purchasers who are influenced by their participation in the residential lighting program to purchase additional non-discounted efficient bulbs.

4.3.2.1 Data Collection

Data collected during in-store intercept surveys with customers purchasing program bulbs should be used to estimate participant spillover. During these surveys, customers purchasing program-discounted and non-discounted efficient bulbs (CFLs or LEDs) should be asked questions to determine whether the residential lighting program influenced their purchases of non-discounted efficient bulbs.

Primary Program Influence Score Question

1. Influence of the lighting program or in-store information on the customer's decision to purchase non-discounted CFLs or LEDs. (0 to 10 scale where 0 is not at all influential and 10 is extremely influential)

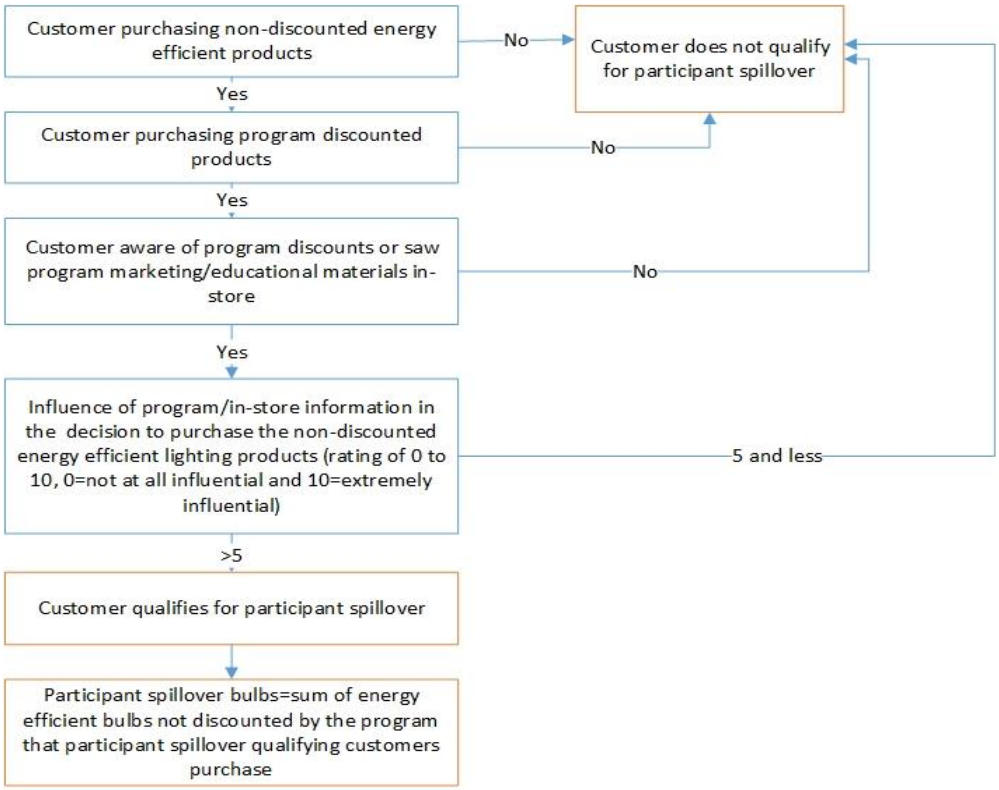
4.3.2.2 Scoring Algorithm

To estimate participant spillover, the number of program-influenced, non-discounted efficient bulbs (CFLs or LEDs) purchased by program participants is divided by the total number of program bulbs purchased by these program participants. This results in the Participant Spillover Rate.

Step 1: Estimate the total number of non-discounted energy efficient bulbs purchased by respondents that had also purchased program-discounted bulbs and were influenced by the program. Respondents who gave a rating of greater than 5 on the program influence question are considered to be influenced by the program.

Figure 4-4 below provides a visual depiction of the process of qualifying non-discounted bulbs as participant spillover bulbs.

Figure 0-4. Residential Upstream Lighting Participant Spillover Determination



Step 2: Calculate the total number of program-discounted bulbs purchased by summing the number discounted bulbs purchased by all respondents.

Program Bulb Purchases = sum(Number of Discounted CFLs or LEDs purchased)

Step 3: Calculate the spillover rate by dividing the total number of spillover bulbs purchased by the total number of program-discounted bulbs purchased.

Spillover Rate = Spillover Purchases/Program Purchases

4.3.3 Nonparticipant Spillover

Nonparticipant spillover results from purchases of non-discounted efficient bulbs by customers who are not purchasing program-discounted bulbs, but report that the residential lighting program influenced their decision to purchase non-discounted efficient bulbs.

4.3.3.1 Data Collection

Data collected during in-store intercept surveys with customers purchasing efficient bulbs not discounted by the program should be used to estimate nonparticipant spillover. During these surveys, customers purchasing non-discounted efficient bulbs (CFLs or LEDs) and not purchasing any program-discounted bulbs should be asked questions about awareness of the program discounts and point-of-purchase program marketing and educational materials. These questions are used to determine whether the residential lighting program influenced their purchases of non-discounted efficient bulbs.

Primary Program Influence Score Question

1. Influence of the lighting program or in-store information on the customer's decision to purchase non-discounted CFLs or LEDs. (0 to 10 scale where 0 is not at all influential and 10 is extremely influential)

4.3.3.2 Scoring Algorithm

The nonparticipant spillover scoring algorithm involves estimating the total number of nonparticipants, the incidence of nonparticipants in the sample, the total number of nonparticipant spillover bulbs, and the average number of nonparticipant spillover bulbs per customer in the sample, and then extrapolating the sample estimates to the population of the utility customers. Below are the steps used to calculate the nonparticipant spillover rate.

Step 1. Determine nonparticipant spillover in the sample by following the steps outlined below.

A. Determine the total number of nonparticipating customers in the survey sample:
Nonparticipating customers (survey) = customers who did not purchase any program-discounted energy efficient lighting products. These customers may have purchased non-discounted energy efficient lighting products, less efficient lighting products or both.

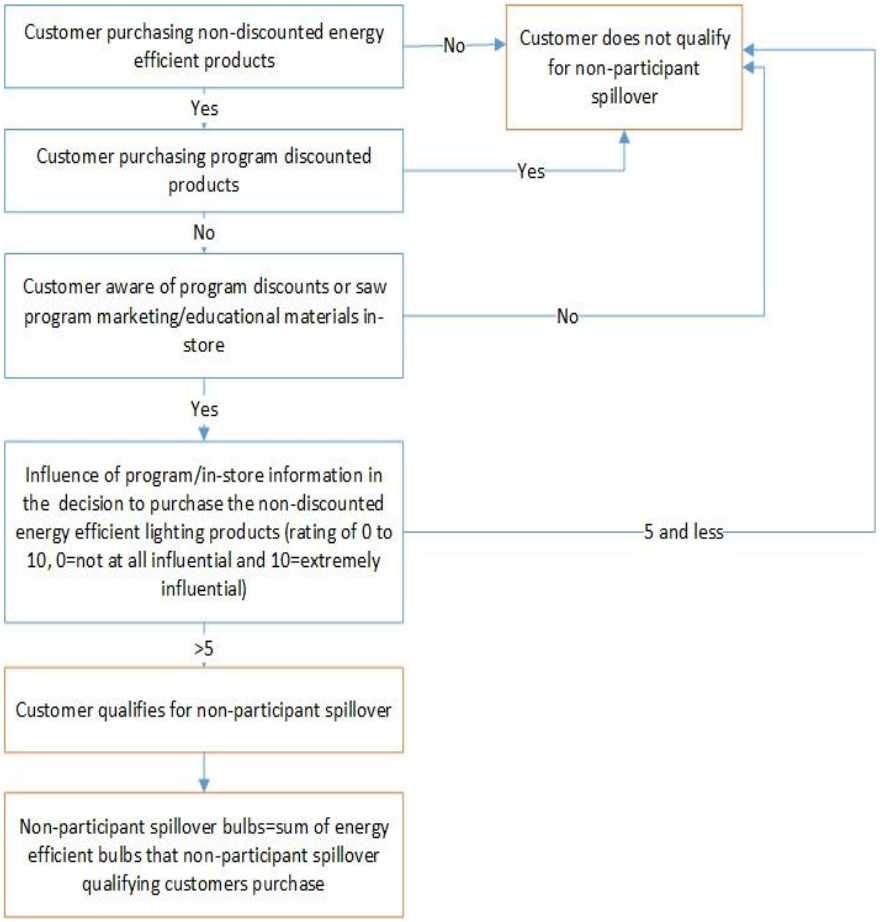
B. Determine the incidence of nonparticipating customers in the survey sample by dividing non-participating customers by total customers in the sample:

Incidence of nonparticipating customers (survey)=Nonparticipating customers (survey)/total customers (survey)

C. Determine total number of nonparticipant spillover bulbs by summing CFLs and LEDs not discounted by the program that were purchased by nonparticipating customers who were aware of the program discounts or marketing promoting energy efficient lighting and were influenced by it. Spillover qualifying bulbs are those purchased by customers who rate the program's influence as greater than 5. The graphic below provides a visual depiction of the process of qualifying non-discounted products as spillover products.

Figure 4-5 below provides a visual depiction of the process of qualifying non-discounted bulbs as nonparticipant spillover bulbs.

Figure 0-5. Residential Upstream Lighting Nonparticipant Spillover Determination



D. Determine the average number of non-participating spillover bulbs per non-participating customer by dividing the total number of non-participating spillover bulbs in the survey by the total number of non-participating customers in the survey.

Average number of nonparticipating spillover bulbs (survey)=total number of nonparticipant spillover bulbs (survey)/nonparticipating customers (survey)

Step 2. Extrapolate nonparticipant spillover to the population

A. Determine the total number of nonparticipating customers in the population by applying the nonparticipant incidence rate from the sample to the population

Total number of nonparticipating customers (population)=Utility residential customer count incidence of nonparticipating customers (survey)*

B. Determine the total number of spillover bulbs by multiplying the average number of spillover bulbs per nonparticipating customer in the survey by the total estimate of nonparticipating customers

*Total number of nonparticipant spillover bulbs=Average number of nonparticipant spillover bulbs (survey)*total number of nonparticipating customers (population)*

Step 3. Calculate nonparticipant spillover rate by dividing the total number of nonparticipant spillover bulbs in the population by the total number of program-discounted bulbs:

Nonparticipant spillover rate=total number of nonparticipant spillover bulbs/total number of program discounted bulbs

4.3.3.3 Method Advantages and Disadvantages

The in-store intercept method described above has certain advantages and disadvantages.

Advantages: This approach catches customers at their point of purchase, before they leave the store and can no longer be contacted directly. Given the interview's timing, customers can more easily recall price factors leading to their purchase choices. Also, as customers are intercepted at the store rather than surveyed by telephone, a higher cooperation rate results.

Disadvantages: Customers may not fully connect the impact that in-store education, product placement, and advertising have on their decision making. While many consumers believe they are not influenced by advertising, retailers know advertising and product placement work. Further, store intercepts typically must be coordinated with education events, and many retailers do not allow interviews to take place in their stores. Consequently, results are not based on random samples of customers purchasing program-discounted lighting throughout the year and across all participating retailers, which could bias the results.

4.5 Prescriptive Rebate (With No Audit) Protocol

Prescriptive Rebate programs typically offer predetermined rebates to residential customers for purchasing measures such as high-efficiency furnaces, clothes washers, brushless/electronically commutated motors (ECMs), boilers, boiler reset controls, water heaters, air-source heat pumps (ASHPs), ground-source heat pumps (GSHPs), central air conditioners (CACs), programmable thermostats, smart thermostats, insulation, air sealing, duct sealing, and desktop power management software. The program may require installation by a registered program ally, but it does not require a home audit (although purchases may be made in response to an audit).

These programs encourage consumers to undertake the following:

- Purchase higher-efficiency equipment than they otherwise would have, had they shopped for such equipment at the same time (replace on burnout); and
- Replace operating but inefficient equipment with higher-efficiency equipment (early replacement).

The basic method for estimating free ridership and participant spillover (See Section 0) for these programs uses a participant self-report, based on a standard battery of questions. An enhanced method may utilize trade ally surveys to provide another quantitative assessment, which may be triangulated with the basic method approach. As discussed further in Section 5.2, trade ally surveys may also be used to assess nonparticipant spillover.

4.5.1 Basic Method

4.5.1.1 Free Ridership

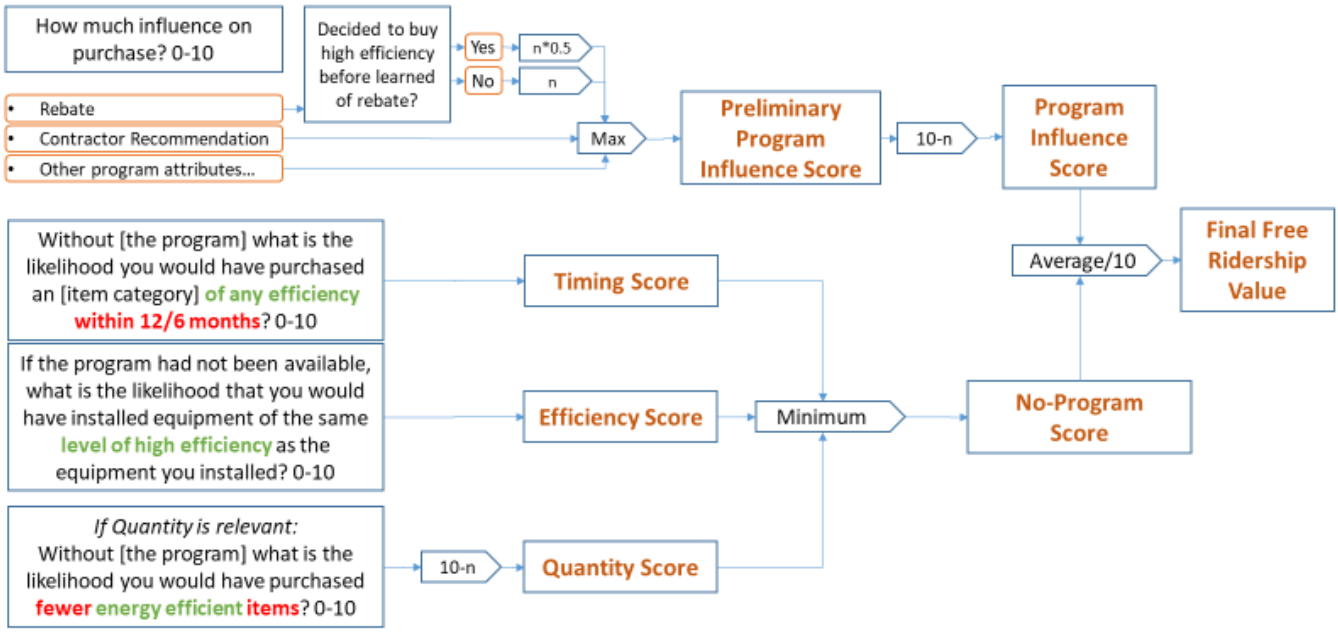
The free ridership assessment battery is brief to avoid applying an undue survey burden, yet it seeks to reduce self-report biases by including two main free ridership components:

- A Program Influence component, based on the participant's perception of the program's influence on carrying out the energy-efficient project; and
- A No-Program component, based on the participant's intention to carry out the energy-efficient project without program funds.

When scored, each component assesses the likelihood of free ridership on a scale of 0 to 10, with the two scores averaged and for a combined total free ridership score. As different and opposing biases potentially affect the two main components, the No-Program component typically indicates higher free ridership than the Program Influence component. Therefore, combining these decreases the biases.

Figure 4-6 illustrates the scoring algorithm.

Figure 4-6. Residential Prescriptive Rebate (With No Audit) Free Ridership



Calculation of the Program Influence Score

Program influence is assessed by asking respondents, on a scale from 0 (not at all important) to 10 (extremely important), how important they found various program elements were on their undertaking the project the way they did. The number of elements included will vary, depending on the program's design. Logic models, program theory, and staff interviews typically inform the list of elements. Programs typically use the following elements to influence customer behavior: information; incentives or rebates; interaction with program staff (i.e., technical assistance); interaction with program proxies, such as members of a trade ally network; building audits or assessments; and financing.

In addition to asking about specific program influences, surveys ask respondents whether they planned to purchase a high-efficiency version of the product before learning of the rebate program. The respondent's rating of the rebate's influence is adjusted by 0.5 for those answering the question "yes."[73] Evaluators should conduct a sensitivity analysis around the use of this adjustment and present it in the report.

The Preliminary Program Influence Score equals the maximum influence rating for any program element rather than, for example, the mean influence rating. This is based on the rationale that if any given program element had a great influence on the respondent's action, then the program itself had a great influence, even if other elements had less influence.

An inverse relationship occurs between high program influence and free ridership: the greater the program influence, the lower the free ridership. The Program Influence (PI) Score = 10 - Preliminary Program Influence Score.

Calculation of the No-Program Score

The No-Program (NP) Score is based on three measures of the likelihood of a participant purchasing equipment of the same level of high efficiency as the unit installed with the program at the same time in the absence of the

[73] The Illinois NTG Working Group discussed using this question to check for consistencies rather than adjusting the score. The NTG working group agreed that it is preferable not to directly ask about conflicting language with residential customers and to utilize an open ended question instead to assess possible reasons for conflicting statements. It is the experience of the NTG working group members that residential customers tend to be more impatient with these types of questions and can typically respond easier to an open-ended question about their motivations.

program. Each of these likelihood measures are assessed on a 0-10 scale in which 0 means not at all likely and 10 means extremely likely.

First, the participant should be asked their likelihood of purchasing an item of *any efficiency* within 12 or 6 months (12 months for a single or big ticket item and 6 months for less expensive items) for the Timing (T) Score. Participants who were influenced by the program to replace still-functioning equipment will likely give a low score to this question, while participants who needed to replace burned out equipment will give a high score. This measure enables the analysis to use a single algorithm for both early replacement and replace-on-burnout scenarios.

Next, the participant should be asked a key question that asks the respondent to gauge their likelihood of purchasing, absent the program, equipment of the same level of high efficiency as the unit installed with the program . This measure forms the Efficiency €€ Score. A respondent stating the likelihood of purchasing an item of the *same level of high efficiency* as a 5 on a scale of 0 to 10 is assigned an Efficiency Score of 5.

If multiple quantities of an item are purchased, the respondent should be asked about the likelihood of purchasing fewer energy-efficient items. The response to this question is subtracted from 10 to compute the Quantity (Q) Score.

The No-Program Score is the minimum of the Timing, Efficiency, and (if applicable) Quantity Scores. Finally, the No-Program Score is averaged with the Program Influence Score to calculate the Final Free Ridership Value.

$$No\ Program\ Score\ (NP) = Min(T, E, Q)$$

$$Free\ Ridership\ (FR) = Mean(PI, NP)$$

Consistency Checks

To address the possibility of conflicting responses (i.e., low intention score and high influence score), the survey should include consistency checks that, at a minimum, ask participants an open-ended question to address the program's influence. For example:

- In your own words, please tell me the influence the program had on your purchase of the <insert measure name>.

In this case, the evaluation analyst will assess the response to this open ended question and its consistency with the other questions, and, if warranted based on clear additional information, they will adjust the score based on expert judgement. If an inconsistency exists and the open-ended response does not resolve the inconsistency, the respondent will be removed from the calculation. All instances of this occurring should be documented in the final report. Additional consistency checks, triggered and resolved within the survey with additional questions to participants, remain optional.

Missing responses to specific questions should be treated as "missing" for that particular question, but the observation or case will be retained in the analysis. Evaluation reports should note if this affects more than 5% of the responses.

4.6 Single-Family Home Energy Audit Protocol

Single-Family Home Energy Audit programs (or energy assessment programs) seek to secure energy savings for residential customers by providing audits, direct-install measures, and incentives for additional energy efficiency opportunities. The participation process generally begins with an energy audit, performed by a program-affiliated companies or individuals; this involves an auditor assessing the customer's home to identify energy-saving opportunities. At that time, the auditor may install free instant-savings measures, such as CFLs, low-flow showerheads, and faucet aerators. Auditors also may educate customers about incentives available through the audit program (e.g., air sealing, insulation) or other Program Administrator-sponsored energy efficiency programs.

For these programs, free ridership and participant spillover (See Section 0) estimates rely on participant self-reports, gathered through surveys.

4.6.1 Basic Method

Given the multiple components of some audit programs, net impacts should be estimated using survey batteries

tailored to a customer's experience (e.g., receipt of free direct-install measures and discounted or rebated measures). The following sections outline the approach for two program components, one dealing with the direct installation of free low-cost measures and a second dealing with envelope measures, such as air sealing and insulation.

4.6.1.1 No-Cost, Direct Install Measures

For free measures directly installed by program staff due to the audit, free ridership calculations should include the following components: Timing, Efficiency, and Quantity.

This approach provides several important benefits, such as deriving a partial free ridership score based on the likelihood that the participant would take similar actions in the absence of the audit. For example, partial scores can be assigned to customers who planned to install the measure, but the program influenced that installation, particularly in terms of timing (e.g., the program might have accelerated the installation) or quantity (e.g., the program might have led to installation of additional program-qualified measures).

Outlines of components and their associated survey questions follow:

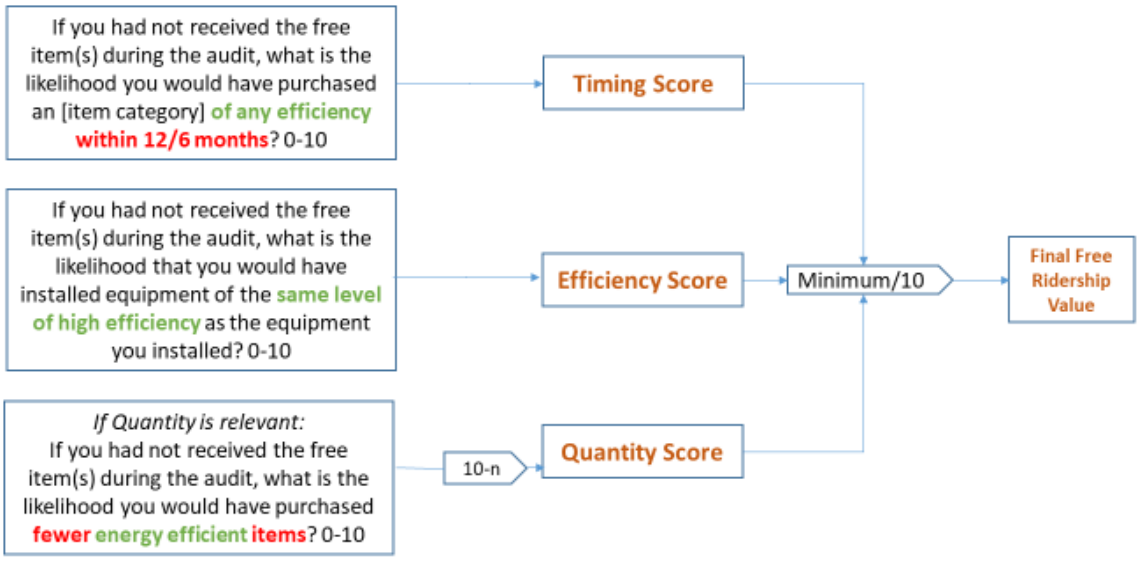
- **Timing (T).** The first question to compute the Timing (T) Score accounts for earlier installation of measures due to the program by asking respondents about their likelihood (0-10 scale) to have installed an item *of any efficiency* within 6 or 12 months, had they not received it through the program (12 months for a single or big ticket item and 6 months for less expensive items).
- **Efficiency (E).** This score reflects the likelihood that customers would have installed equipment, absent the program, of the same level of high efficiency as the unit installed with the program. For free measures, this is based on a question asking respondents to rate the likelihood that they would have installed equipment of the same level of high efficiency as the unit installed had they not received them for free through the audit (on a 0 to 10 scale, where 0 is not at all likely and 10 is extremely likely). A higher likelihood value means a higher level of free ridership (i.e., a lower attribution level for the program).
- **Quantity (Q).** The question to compute the Quantity (Q) Score asks respondents about the likelihood that they would have installed fewer measures or performed less weatherization without the program. The response to this question is subtracted from 10 to compute the Quantity Score, as a lower score means a greater likelihood the respondent would have installed the same or a greater number of measures.

Given the low cost of the measures provided through the direct-install component of most audit programs and the number of measures received per participant, efforts have been made to streamline the free ridership battery to reduce the respondent's burden. As such, the overall Final Free Ridership Value per measure can be calculated by taking the minimum of the Timing, Efficiency, and Quantity Scores, as shown in the following equation:

$$Free\ Ridership\ (FR) = Min(T, E, Q)$$

Figure 4-7 illustrates the algorithm for no-cost measures.

Figure 4-7. Single-Family Home Energy Audit Free Ridership—No Cost Measures



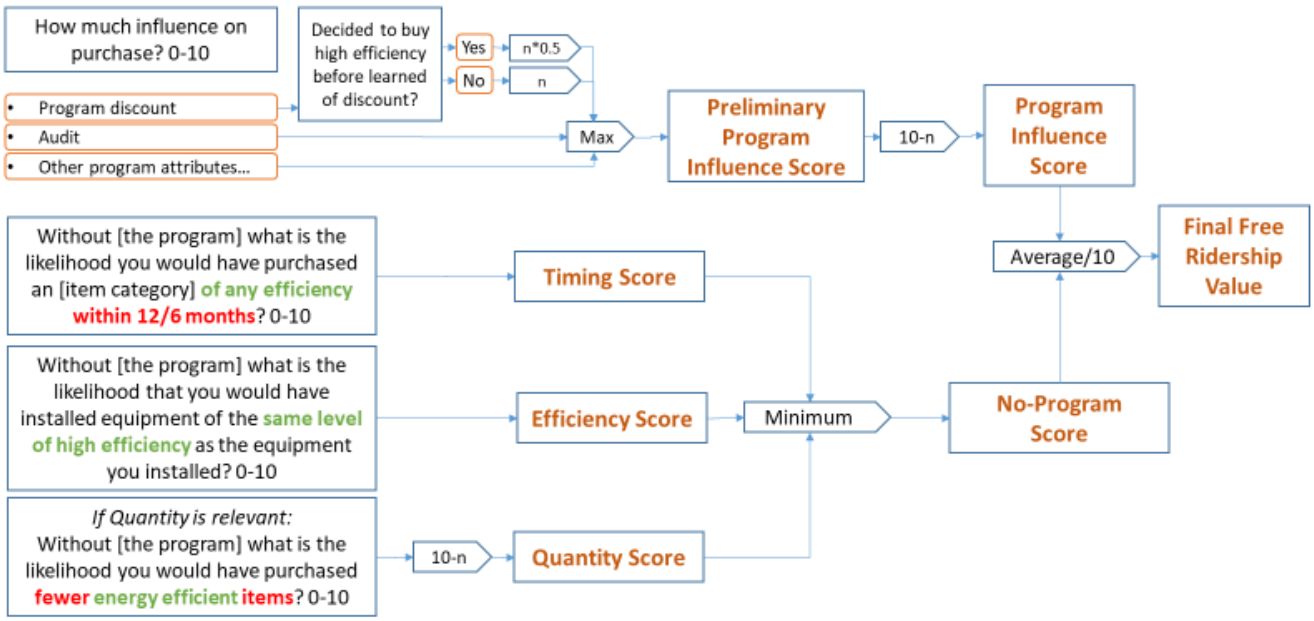
4.6.1.2 Rebated/Discounted Measures

Estimating NTG for rebated measures (typically for building shells) requires a more rigorous process than estimating NTG for free direct-install measures. In particular, the approach integrates an assessment of various program components that may have influenced the participant's installation of the measures. For discounted envelope measures, the basic free ridership factor consists of the following two components:

- A Program Influence component, based on the participant's perception of the influence of various program elements—including the discount and the audit itself—on carrying out the energy-efficient project; and
- A No-Program component, based on the participant's likelihood of purchasing equipment, absent the program, of the same level of high efficiency as the unit installed at installed at the same time.

The free ridership method for discounted measures is identical to that used in the Prescriptive Rebate (With No Audit) protocol, with the one exception that the questions about program influence should be sure to include the audit itself as one of the program attributes. Evaluators should refer to Section 0 for details of the method. Figure 4-8 illustrates the algorithm for discounted measures.

Figure 4-8. Single-Family Home Energy Audit Free Ridership—Discounted Measures



4.6.1.3 Consistency Checks

To address the possibility of conflicting responses (e.g., the high likelihood to install the same measure in the program's absence and the high importance of program factors), the survey should include consistency checks that, at a minimum, ask participants an open-ended question to address a program's influence, such as the following:

- In your own words, please tell me the influence the program had on your purchase of the <insert measure name>.

For low or no-cost, direct-install measures, surveys should include two questions to assess a program's influence on the respondent. The first should be asked at the beginning of the NTG battery, and the second should be asked at its conclusion. Questions include the following:

- Prior to the audit, had you purchased any <measures>? Y/N
- IF YES AND LIKELIHOOD TO INSTALL WITHOUT THE PROGRAM IS <7: Given that you had purchased <measures> before receiving the audit, why didn't you purchase additional <measures> on your own without the program? [OPEN END]
- IF NO AND LIKELIHOOD TO INSTALL WITHOUT THE PROGRAM IS >6: Given that you have not purchased <measures> before, why were you likely to purchase <measures> on your own without the program? [OPEN END]

In both cases, the evaluation analyst will assess responses to open ended questions and their consistency with the other questions; if warranted, based on clear additional information, the evaluator will adjust the original question score if required. If inconsistency occurs and the open-ended response does not resolve it, the original question response will be removed from the calculation. Final reports should document all instances of such adjustments. Optionally, additional participant questions can be included to trigger and resolve additional consistency checks.

Missing responses to specific questions (e.g., don't know or refused) should be treated as "missing" for those particular questions, but the analysis retains the observation or case. The evaluation reports should note if this affects more than 5% of responses.

4.7 Multifamily Protocol

Multifamily energy efficiency programs typically offer direct installation of low-cost, energy-efficient measures in multifamily dwelling units, in addition to rebates for common area lighting retrofits, air sealing, insulation, and improvements to HVAC systems and controls. These programs have various target audiences from owners, managers, or developers of market rate multifamily housing to those operating lower income or assisted living housing. Across these groups, properties must generally have a minimum of between three and five units to qualify for the programs.

Most multifamily program savings are typically achieved by encouraging customers to install higher-efficiency equipment than they would have installed on their own. However, programs may also encourage early replacement of still functioning equipment that is less efficient, thus impacting the timing of the installation, so that savings is realized earlier. The incentive may also make it more affordable for customers to install a greater number of high-efficiency measures.

The basic method for estimation of free ridership and participant spillover (See Section 0) for these types of programs is based on participant self-report gathered through surveys. For common area and building shell components of the program, participants are property managers and owners responsible for building maintenance and renovation. However, depending on the program design for the in-unit component of the program and specifically the installation of efficient lighting, participating in the program (i.e., install program measures) may be driven by either property managers/owners or tenants or, potentially, both. This distinction is due to the fact that in some market-rate apartments, the tenant is responsible for decisions related to the installation of program measures, including light bulbs, while this is not common practice in income-qualified or assisted-living settings. For other in-unit measures, such as faucet aerators and low-flow showerheads, evaluators interview property managers/owners regarding program influence, as these measures are typically direct installed by program staff, and there is a limited likelihood of tenants making changes to these features.

4.7.1 Basic Method

Estimating NTG for rebated measures requires a more rigorous process than estimating NTG for free direct-install measures. In particular, the approach integrates an assessment of various program components that may have influenced the participant's installation of the measures. For discounted measures, the basic free ridership factor consists of the following two components:

- A Program Influence component, based on the participant's perception of the influence of various program elements—including the discount and the audit itself—on carrying out the energy-efficient project; and
- A No-Program component, based on the participant's likelihood of purchasing equipment, absent the program, of the same level of high efficiency as the unit installed at the same time in the absence of the program.

The free ridership method for discounted measures is identical to that used in the Prescriptive Rebate (With No Audit) protocol, with the one exception that the questions about program influence should be sure to include the audit itself as one of the program attributes. Evaluators should refer to Section 4.4.1.1.1 and 4.4.1.1.2 for details of the method. Figure 4-9 and Figure 4-10 also illustrate the algorithms for CFL/LED and non-CFL/non-LED measures[74].

[74] Evaluators should word the survey questions to reflect whether measures were free or purchased with an incentive.

Figure 4-9. Multifamily Free Ridership—Non-CFL/Non-LED Measures

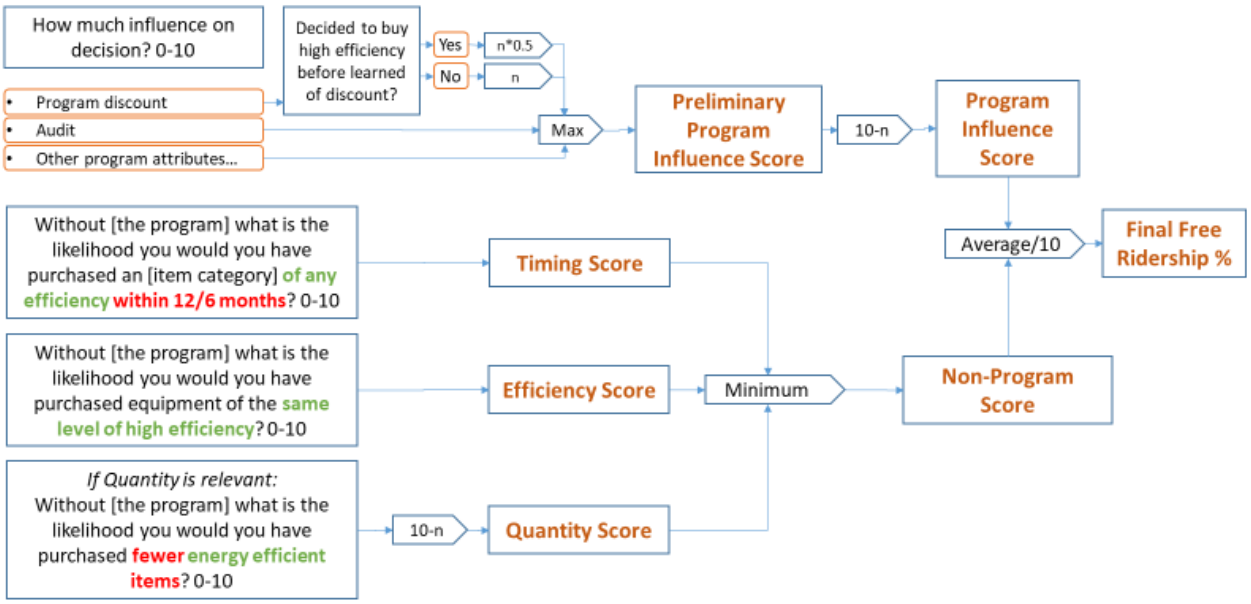


Figure 4-10. Multifamily Free Ridership for Property Managers—CFL/LED Measures

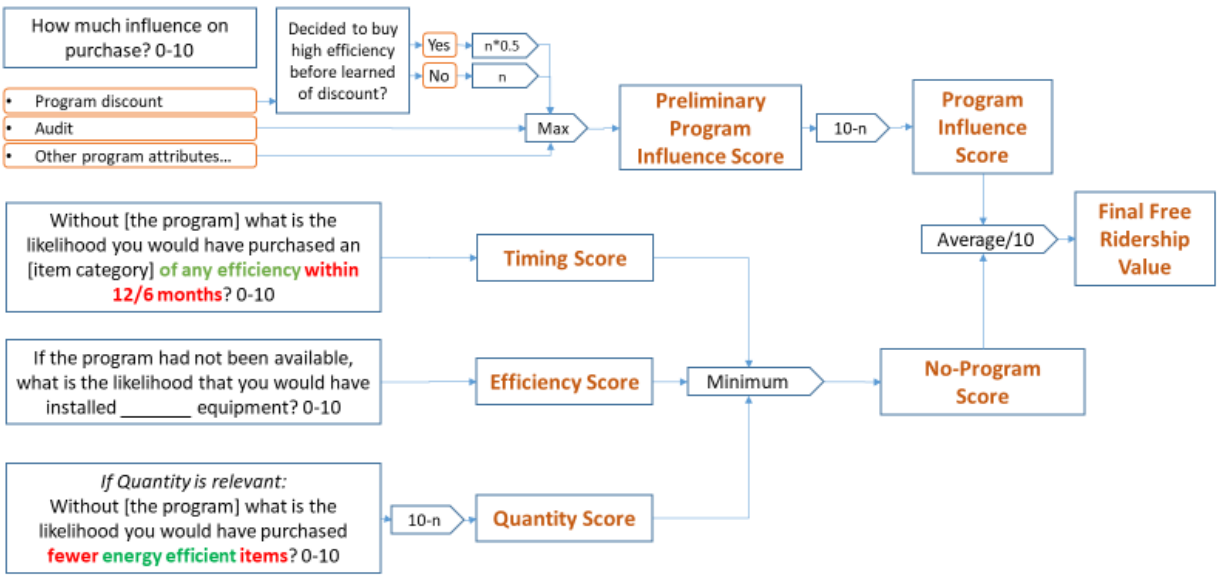


4.7.1.1 Consistency Checks

To address the possibility of conflicting responses (e.g., high likelihood to install the same measure without the program, high importance to program factors), the survey should include consistency checks that, at a minimum,

ask participants an open-ended question to address the program's influence. For example[75]:

- In your own words, please tell me the influence the program had on your purchase of the <insert measure name>.

The evaluation analyst will assess the responses to the open ended questions and their consistency with the other survey questions, and, if warranted based on clear additional information, will adjust the original question score. If the open-ended response does not resolve the inconsistency, responses to the original question should be removed from the calculation. The survey may include additional consistency check triggers and resolutions through additional participant questions. The final report should document how often the consistency check rules were triggered, how often adjustments were made to scores, and how often inconsistencies could not be resolved.

Missing responses to specific questions (including don't know or refused) should be treated as missing for that particular question, but the analysis should retain that observation or case. Evaluation reports should note if this affects more than 5% of the responses.

4.7.1.2 Data Collection

A participant survey should be used as the primary source of data collected for estimating free ridership in residential multifamily programs. As discussed, evaluators may field surveys with owners, property managers, or tenants, depending on a program's design and theory. Determining the appropriate audience from which to gather information for estimating free ridership depends on the program's design, and, ultimately, the party responsible for deciding to install specific program measures.

4.8 Energy Saving Kits and Elementary Education Protocol

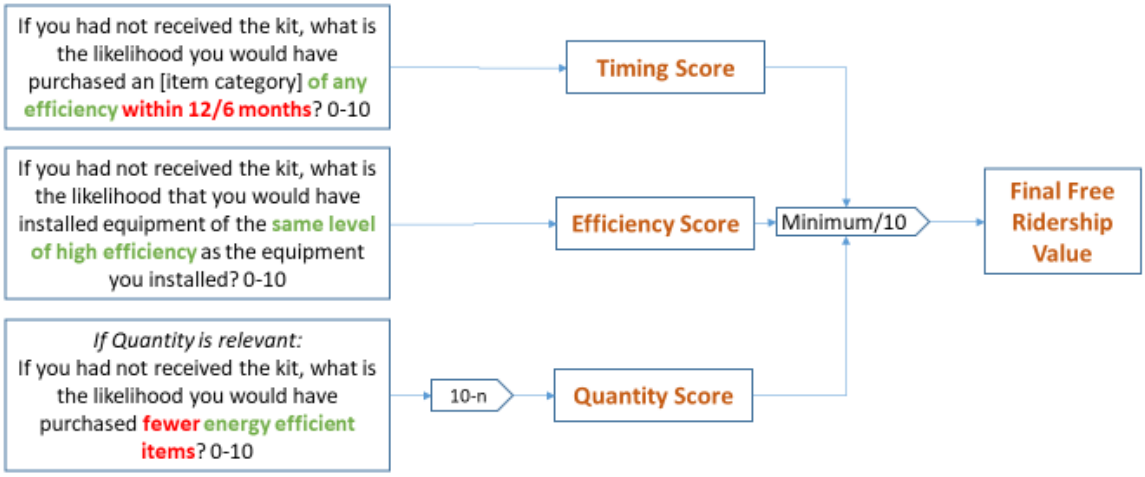
Energy Saving Kits and Elementary Education Programs aim to secure energy savings through the distribution of kits containing various energy-saving measures, including (but not limited to): high-efficiency lighting (CFLs or LED lamps); bathroom and kitchen faucet aerators; and low-flow showerheads. Energy Saving Kits operate as an opt-in program; customers can request a kit by completing an Internet or phone application. Elementary Education Program participants do not request a kit as kits are distributed to all students in a classroom.

Free ridership and participant spillover (See Section 0) estimations for both programs rely upon participant self-report information gathered through surveys, despite the differences in distribution models. This methodology can be used for other energy-saving kit programs, including kits with alternative distribution methods (e.g., kits dropped off at a participant's home).

The following section contains a description of the basic NTG method used. Figure 4-11 illustrates the method.

[75] Evaluators should word the consistency check questions to reflect whether measures were free or purchased with an incentive.

Figure 4-11. Energy Saving Kits and Elementary Education Free Ridership



4.8.1 Basic Method

Free ridership calculations should include the following components: No-Program, Timing, and Quantity.

This approach provides several important benefits, such as the ability to derive a partial free ridership score based on the likelihood that similar actions would have taken place, even if the participant had not received a kit. For instance, partial scores can be assigned to customers with plans to install the measure, but the program at least influenced that installation, particularly in terms of timing (e.g., the program might have accelerated the installation) or quantity (e.g., the program might have led to the installation of additional measures).

Outlines of components and their associated survey questions follow:

- **Timing (T).** The first question computes the Timing (T) Score accounts for earlier installation of measures due to the program by asking respondents about their likelihood (0-10 scale) to have installed an item *of any efficiency* within 6 or 12 months, had they not received it through the program (12 months for a single or big ticket item and 6 months for less expensive items).
- **Efficiency (E).** This score reflects the likelihood that customers would have installed equipment of the same level of high efficiency as the unit installed absent the program. This is based on a question asking respondents to rate the likelihood that they would have installed measures of the same level of high efficiency had they not received them for free through the kit (on a 0 to 10 scale, where 0 is not at all likely and 10 is extremely likely). A higher likelihood value means a higher level of free ridership (i.e., a lower attribution level for the program).
- **Quantity (Q).** The question to compute the Quantity (Q) Score asks respondents about the likelihood that they would have installed fewer measures without the program. The response to this question is subtracted from 10 to compute the Quantity Score, as a lower score means a greater likelihood the respondent would have installed the same or a greater number of measures.

Given the low cost of measures provided in the energy-saving kits as well as the number of measures included in each kit, efforts have been made to streamline the free ridership battery to reduce the respondent's burden. As such, the overall Final Free Ridership Value per measure can be calculated by taking the minimum of the Timing, Efficiency, and Quantity Scores, as shown in the following equation:

$$Free\ Ridership\ (FR) = Min(T, E, Q)$$

Missing responses to specific questions (e.g., don't know or refused) should be treated as "missing" for that particular question. Despite missing responses, the case will be retained in the analysis (pairwise deletion). The

evaluation reports should present the percent missing for each of the three questions.

4.8.1.1 Data Collection

Evaluators should use a participant survey as the primary data collection source for estimating free ridership in Energy Saving Kits and Elementary Education Programs. As a general rule, a free ridership rate should be calculated for each separate kit component, and then be weighted by savings to determine the program-level results.

4.9 Residential New Construction Protocol

Residential New Construction programs typically offer builder training, technical information, marketing materials, and incentives to builders for the construction of eligible homes. Eligible homes must meet specific standards, designed to achieve energy efficiency levels above local building codes. Programs may use different tiers of standards to meet correspondingly different incentives.

The basic method for estimating free ridership and participant spillover for these programs is based on builder participant self-reporting, gathered through surveys.

The following section describes the basic method used.

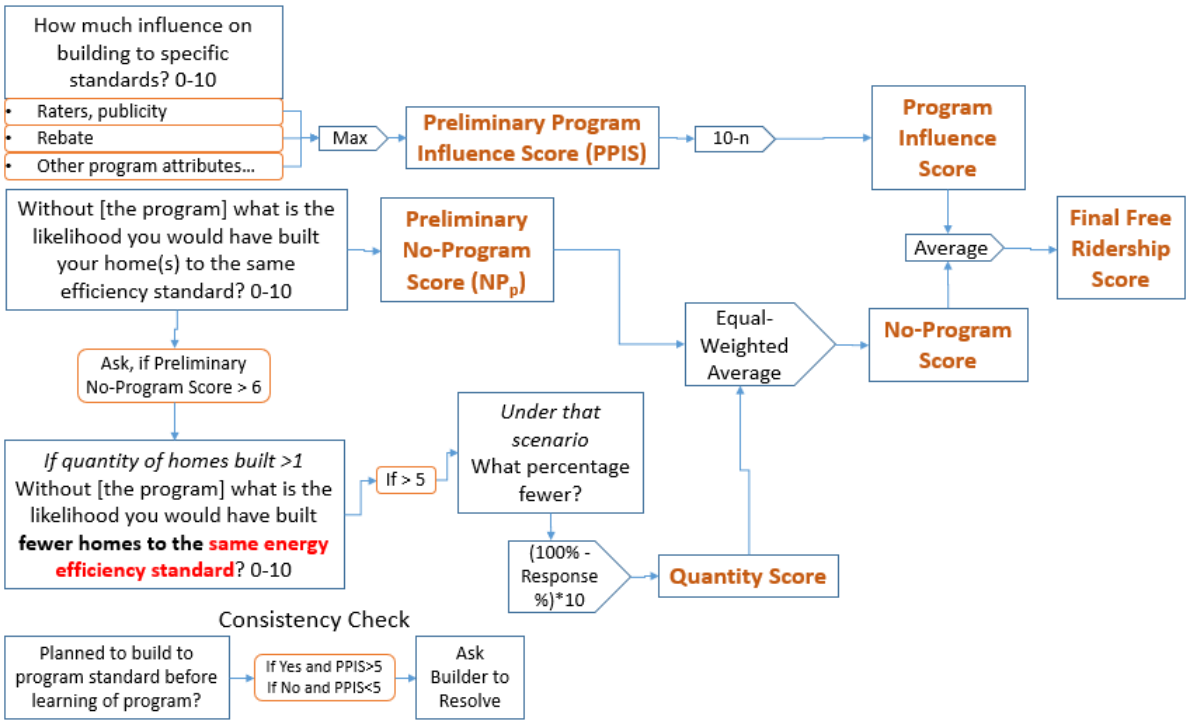
4.9.1 Basic Method

For this program, a free rider is a builder who would have constructed a home at the program's efficiency level in the program's absence. Given the multiple methods available to achieve desired home energy efficiency levels, survey questions consider the builder's likelihood of meeting the same energy efficiency standard, rather than whether or not the builder would have installed certain energy efficiency measures. Figure 4-12 (below) illustrates the method in more detail.

Evaluators assess Program Influence by asking respondents, on a scale from 0 (not at all important) to 10 (extremely important), how important they found various program elements in deciding to build to specific energy efficiency standards. The number of elements included vary, depending on the program's design. Logic models, program theory, and staff interviews typically inform the list of program elements included. Programs typically use the following elements to influence builder actions: marketing materials; incentives or rebates; contacts with HERS Raters; and technical assistance.

In addition to asking about specific program influences, surveys should ask builders whether they planned to build homes to the same standard before learning of the program.

Figure 4-12. Residential New Construction Free Ridership



4.9.1.1 Calculation of the Program Influence Score

The Program Influence Score (PI) equals 10 minus the maximum influence rating for any program element rather than, for example, the mean influence rating. This is based on the rationale that if any given program element had a great influence on the respondent's action, the program itself had a great influence, even if other elements had less influence.

4.9.1.2 Calculation of the No-Program Score

Evaluators calculate the No-Program score using a set of questions that ask respondents to gauge their likelihood of building homes to the same standards and in the same quantities had the program not existed. Three separate responses are considered in calculating the No-Program Score:

- The likelihood, on a scale of 0 to 10, that the builder would have built their homes to the same efficiency standard (Preliminary No-Program Score (NP_p))
- If that likelihood is greater than 6, the likelihood of fewer homes being built to the same efficiency standard.
- If that likelihood is greater than 6, the response to the question "for that scenario, what percentage of fewer homes would be built to the standard?" (Quantity Score = (100% - % answer) * 10, which will be a number between 0 and 10)

The resulting No-Program (NP) Score is calculated as follows:

$$NP = Mean(NP_p, Q)$$

The overall Free Ridership Value derives from the average of the PI and NP scores, as shown in the following formula:

$$FR = Mean(PI, NP)$$

4.9.1.3 Consistency Checks

To address the possibility of conflicting responses (e.g., the high likelihood to build to the same efficiency standards

without the program, the high importance of program factors), the survey should include, at a minimum, consistency checks that ask participants an open-ended question to address the program's influence. For example:

- In your own words, please tell me the influence the program had on your building practices.

If a high (>6) Preliminary Program Influence Score (PPIS) results, yet the builder planned to meet the same efficiency standard prior to learning of the program; or if the Preliminary Program Influence Score is lower (<7), and the builder did not plan to build to the standards prior to learning of the program, the survey should include a question to determine why this occurred, using wording that gets at the following inconsistencies:

- IF Preliminary Program Influence Score is >6 and Builder planned to meet the same efficiency standard prior to learning OF THE PROGRAM: Given that you had plans to meet the standard prior to learning about the program, why do you think the <program elements> were influential in your meeting the standard? [OPEN END]
- IF Preliminary Program Influence Score is <7 and Builder had no plans to meet the same efficiency standard prior to learning of the program: Given that you had no plans to meet the standard prior to learning about the program, why do you think the <program elements> were not more influential in your meeting the standard? [OPEN END]

The evaluation analyst will assess the responses to the open ended questions and their consistency with the other survey questions, and, if warranted based on clear additional information, will adjust the original question score. If the open-ended response does not resolve the inconsistency, responses to the original question should be removed from the calculation. The survey may include additional consistency check triggers and resolutions through additional participant questions. The final report should document how often the consistency check rules were triggered, how often adjustments were made to scores, and how often inconsistencies could not be resolved.

Missing responses to specific questions (including don't know or refused) should be treated as missing for that particular question, but the analysis should retain that observation or case. Evaluation reports should note if this affects more than 5% of the responses.

4.9.2 Participant Spillover

Participant spillover occurs when, due to program participation, a builder increases the energy efficiency of homes built outside the program (but inside a utility's service territory) by adopting certain building practices used in participating homes. Participant spillover can be calculated based on participant builder survey questions that ask builders about homes built within the utility service territory but outside the program. Survey questions ask whether the builder increased the energy efficiency standards of non-program homes after participating in the program, and the number of homes they applied these increased standards to, within the utility's service territory. Depending on the program characteristics, spillover should be measured as changes in specific building practices or as installation of specific measures. The text below assumes the program has been targeted at modifying building practices.

Spillover may be recorded depending on responses to the following questions:

1. How important was your experience in the <PROGRAM ADMINISTRATOR'S> program in your incorporating this building practice your other homes, using a scale of 0 to 10, where 0 is not at all important and 10 is extremely important?
2. If you had not participated in the <PROGRAM ADMINISTRATOR'S> program, how likely is it that you would still have incorporated this building practice using a 0 to 10, scale where 0 means you definitely WOULD NOT have implemented this practice and 10 means you definitely WOULD have implemented this practice?

Responses to the first question establish the Practice Attribution Score 1, and responses to the second question establish the Practice Attribution Score 2. Spillover may be program-attributable for building practices with self-report data meeting the following condition:

$$\textit{Spillover Score} = (\textit{Practice Attribution Score 1} + (10 - \textit{Practice Attribution Score 2}))/2 > 5.0$$

For responses meeting these conditions, an evaluator determines that specific building practices referenced in the question are attributable to the program; otherwise, the evaluator determines that specific building practices

referenced in the question are not attributable to the program. The attribution criteria represent a threshold approach, in which energy impacts associated with building practices program participants implement outside the program are either 100% program-attributable or 0% program-attributable.

For each building practice discussed, builders will be asked how they know the building practice is more efficient than other options. If the respondent can identify the building practice as ENERGY STAR or name an efficiency level that the evaluator confirms as above the minimum federal standard, or if they identify a technology that the evaluator can confirm is above the minimum federal standard, this counts towards participant spillover.

Finally, depending on the building practice cited by the builder, follow-up questions should ask customers to provide reasonable information to allow the evaluator to estimate the amount of savings using IL-TRM protocols, such as quantity of appliances or the location and amount of insulation.

To calculate the spillover energy and demand savings for these actions, further questions should be asked to assess the gross savings of the building practice, through the appropriate version of the IL-TRM, if available, and the number of homes to which it applied. To develop the Spillover Rate, the total energy and demand impacts from the sampled participants who implemented efficient building practices in other homes due to participation in the program is summed, and then this sum is divided by the total ex post gross impacts from all participants who took the survey.:

$$Participant\ Spillover\ Rate\ (PSO) = \frac{Sum\ of\ Energy\ or\ Demand\ from\ Additional\ EE\ Practices}{Sample\ Ex\ Post\ Gross\ Energy\ or\ Demand\ Impacts}$$

The equation used to adjust the Core NTGR based on participant spillover is as follows:

$$NTGR = (1 - FR + PSO)$$

4.9.2.1 Sample

The sample for a spillover survey should be a random sample of current and up to one year previous program participants. Regardless of the year of participation, spillover should be measured within the set of homes that were completed within 12 months of the survey date.

4.9.3 Builder Nonparticipant Spillover

In addition to participant free ridership and spillover, new construction programs may create NPSO through builders exposed to the program but not actually participating. Rather, they implement some or all of the efficiency measures incorporated through the program in order to compete with builders that are participating.[76] NPSO caused by builders can be determined by surveying two groups of builders:

- "Drop out" builders, who participated in the program previously but have not participated in the past 12 months.
- True nonparticipating builders that report they were aware of the program or that other builders were taking steps to improve new home efficiency, but had never participated.

Surveys ask nonparticipating builders if their knowledge of other builders' increased focus on energy efficiency influenced their building practices and in what manner, to quantify the program's impact on nonparticipating homes. The survey questions will first identify specific building practices that go beyond the implemented energy code for the specific jurisdiction in which the builder is active. Table 4-8 lists the latest building energy code in place for most areas of Illinois. Evaluators should make efforts to ensure the building code under enforcement for each jurisdiction is used as the baseline when evaluating spillover savings.

[76] NPSO also can arise from nonparticipating customers as a direct result of general energy efficiency education and promotion efforts. A separate protocol addresses such NPSO. Care should be taken to ensure the different approaches do not double-count NPSO.

Table 4-8. IECC 2015 Building Energy Code

Component	IECC 2015
Thermostat	Heating 72F; Cooling 75F Programmable Thermostat
Ceiling	U-0.026
Walls	U-0.060
Floors	U-0.033
Slab	R-10, 2ft
Windows	U-0.32
Infiltration	5ACH50
Duct Leakage	4CFM/100CFA
Duct Insulation	R-8 Attic Supply, R-6 Otherwise
Heat Pump	8.2 HSPF
Furnace	80 AFUE
Component	**IECC 2015**
Boiler	82 AFUE
AC	13 SEER
Lighting	75% CFL
Appliances	RESNET Default
Gas Water Heat*	0.58 EF
Electric Water Heat*	0.92 EF

*EF varies based on water heater storage volume and draw pattern; values in table for 40 gallon water heater with medium draw pattern.

For each component that is more efficient than code, the following additional questions are asked:

1. How many homes did you sell in <period> that incorporated this upgrade?
2. Of these homes, how many would have incorporated this upgrade, had the <program> not existed?

Evaluators should ensure that nonparticipant builders receive sufficient time to collect specific data and not rely on "guesses" to respond. Responses should also clarify whether sales counts are specific to the utility service territory in question.

The following steps calculate the program's nonparticipant builder spillover percentage:

1. Compute the difference between the total reported number of efficiency upgrades sold and the total that would have been sold in the program's absence to obtain the total number of upgrades by type of upgrade for that builder.
2. Multiply the total net number of upgrades of each type sold by each surveyed builder by the average gross unit savings for each upgrade type.
3. Sum the result for each builder from the previous step, and weight the results by the ratio of the population of non-active builders to the sample to compute the total spillover energy over the program period.
4. Divide the spillover energy savings by program gross savings.

Should a general population survey be implemented for nonparticipant spillover, care should be taken to ensure spillover is not double-counted.

5 Cross-Sector Protocols

The following sections include protocols that may be applicable to programs in the residential as well as in the commercial, industrial, and public sectors. Table 3-1 Commercial, Industrial, and Public Sector Programs and Table 4-1 Residential and Low Income Programs present information regarding the applicability of these protocols to specific programs.

5.1 Combining Participant and Trade Ally Free Ridership Scores

For a program where trade allies play a prominent role in delivering the energy efficiency measure and promoting the program, an estimate of free ridership from trade allies can be combined with one from participants to form a combined free ridership value. This section discusses combining a **program-level** free ridership score from trade allies with a program-level free ridership score from participants.

If an evaluation uses this approach, the evaluator's NTG report should present the conditions that support the argument that the combined value is more likely to be reflective of reality. That argument should consider the following topics:

1. **Trade Ally Role.** What role do the trade allies play in the program? How were participating trade allies chosen? How might they differ from nonparticipating trade allies? Why does that support the proposition that their view on free ridership is accurate and reasonably unbiased?
2. **Participant Role**. What role do the participants play in deciding which measures are installed and why does that support the proposition that their view on free ridership is accurate and reasonably unbiased?
    a. For example, the participant's role in the decision **may** be significantly less in some types of programs like new construction or multifamily direct install programs. (The participant free ridership data collection method may already account for this by, for example, treating the building owner as the participant rather than the tenants.)
3. **Market Conditions**. What conditions exist in the market that support the proposition that either the trade allies' view or the participants' view on market behavior may be more accurate?
    a. For example, if the market was in its infancy before the program began and as a result participants' ability to take the energy efficiency action was limited, the trade allies may have a more accurate view on the counterfactual than the participants.
4. **Bias.** What are the hypothesized biases of the participants and trade allies? Where do they stem from? What evidence is there that they exist? How well has the data collection approach sought to mitigate that bias?
5. **Offsetting Bias.** Do the hypothesized biases of participants and trade allies offset each other, or do they move the free ridership value in the same direction?

5.1.1 Trade Ally Free Ridership Calculation

The NTG protocols do not yet contain a standardized approach for measuring free ridership from trade allies. That approach should be developed for future versions of the TRM. In the meantime, if an evaluation team decides to estimate trade ally free ridership, they should collaborate with other Illinois evaluators on the survey design and calculation algorithm.

5.1.2 Triangulation

Where appropriate, evaluators should combine participant and trade ally free ridership values by weighting each value in the final result. The weighting of each value should be based on considerations of the likely bias, accuracy, and representativeness of the results. The following presents one approach for determining weights. This is an example only. The evaluator should create an approach appropriate for the program.

Example. Combined participant and trade ally free ridership results by rating the analysis methodology and data collected using responses (rated on a scale of 0 to 10) to the following three questions:

1. All things being equal, on a scale of 0 to 10, with 0 being not at all likely and 10 being extremely likely, how likely is the approach to provide a more accurate estimate of free ridership?
2. Similarly, on a scale of 0 to 10, with 0 being not at all valid and 10 being extremely valid, how valid and reliable is the data collected and the analysis performed (i.e., consider non-response bias, missing data (e.g., whether data collected was based on recollection or record keeping?)
3. On a scale of 0 to 10, with 0 being not at all representative and 10 being extremely representative, how representative is the sample (accounting for sampling error {confidence and precision}, and non-response bias, and any sample frame bias)?

The weight for each free ridership estimate is the average score for that estimate divided by the sum of the average scores for both estimates.

Table 5-1 provides an example scoring illustrating the calculated weights.

Table 5-1. Example Triangulation Weighting Approach

NTG Triangulation Data and Analysis	Participants	Trade Allies
1. How likely is this approach to provide an accurate estimate of free ridership?	6	8
2. How valid is the data collected/analysis?	3	5
3. How representative is the sample?	8	10
Average Score	5.7	9
Sum of Averages	14.7	14.7
Weight	39%	61%

5.2 Spillover Measured Through Trade Allies

Many energy efficiency programs rely on trade allies to help spread program awareness and promote energy efficiency among their customers. Some programs establish lists of participating trade allies and provide trade allies with training, education, and/or marketing materials. Spillover might occur when a trade ally's business practices are influenced by a program but at least some of their energy efficient installations do not receive a program incentive.

For the purposes of measuring trade ally spillover, we define trade allies as (1) retailers, contractors or other market actors who work with end-user customers on the selection and installation of energy-using equipment; and (2) distributors who supply equipment to stores and other market actors, rather than to end-user customers. For the purposes of this section, manufacturers are not included in the definition of trade allies.[77] In addition, we differentiate between the following types of trade allies:

1. Active Trade Allies
    a. Trade allies who were active in the program during the evaluation period and appear in program tracking databases. The tracking data contains information on the quantity of incented measures associated with these trade allies and their savings.
2. Inactive Trade Allies
    a. Trade allies who are on the utility's trade ally list (and have received at least some utility training or education) but who were not active during the evaluation period and do not appear in program savings tracking databases for the evaluation period;
    b. Trade allies who were previously active in the program (and may have been on the utility's trade ally list) but have dropped out; and/or
    c. Trade allies who have never been active in the program and were never on the utility's trade ally list.

[77] The exclusion of manufacturers from the definition of trade ally does *not* suggest that manufacturers cannot create spillover. Rather, manufacturers are excluded because the methodologies outlined in this section do not apply to them.

When deciding whether to conduct trade ally spillover research, the evaluator should consider the following:

- **Likelihood of trade ally spillover:** When limited evaluation resources are available, the evaluator should weigh the likelihood of trade ally spillover against the cost of the analysis when prioritizing evaluation efforts. E.g., programs that provide incentives, but no training or education are less likely to generate spillover than programs that do provide training or education. Similarly, spillover from active trade allies is generally more likely than spillover from inactive trade allies, and spillover from inactive trade allies who have previously been active in the program is generally more likely than spillover from inactive trade allies who have never been active in the program.
- **Potential double-counting of spillover reported by end-use customers and trade allies:** Spillover from active trade allies and spillover from inactive trade allies are mutually exclusive, i.e., as long as the populations and samples are correctly defined, there is no danger of double-counting spillover from these two groups (see also discussion in Section 0). However, if the evaluator measures spillover through trade allies and end-use customers for the same evaluation period, care needs to be taken to avoid double-counting. Evaluators should clearly document potential double-counting of spillover and the steps taken to avoid it.

The following subsections provide suggested approaches for measuring spillover from active and inactive trade allies. Different approaches are outlined for these two groups because of the different types of data available for each of them. For active trade allies, program tracking data contains information on their program activity (the quantity of incented measures associated with each active trade ally and their savings). This data allows for a more rigorous spillover methodology than can be used for inactive trade allies, for whom this information does not exist.

5.2.1 Spillover from Active Trade Allies

Trade allies that are active in an energy efficiency program are more likely to create spillover than inactive trade allies, as their exposure to any program messaging and training/education is likely to be current and therefore more influential on their business practices. Active trade allies may create spillover if their program participation changes their business practices and leads to the completion of non-incented energy efficient projects that would otherwise not have happened. For example, as a result of program training, a trade ally might feel more comfortable talking about the benefits of energy efficiency and recommend energy efficient solutions more often. If these recommendations result in energy efficient projects, but no incentive is claimed, spillover from inactive trade allies may be present.

For active trade allies, the spillover methodology varies slightly for downstream programs and midstream programs. Approaches for both types of program are discussed below.

5.2.1.1 Downstream Programs

Surveys can be used to ask active trade allies if the program influenced their sales of high-efficiency equipment to participating or nonparticipating customers and to quantify the program's impact on their high-efficiency sales. To assess if a sampled trade ally created spillover, the following screening criteria are recommended (the order of these may be adjusted by the evaluator):

1. The percentage of the trade ally's installations/sales that are high efficiency and/or the total volume of high efficiency installations/sales increased since the trade ally became exposed to the program.
2. The trade ally rated the program as important to at least one of these (as described above) high efficiency installation increases.
3. The trade ally installed/sold at least some high efficiency equipment or products during the evaluation period that did not receive an incentive.
4. The trade ally's recommendation was influential in the customers' choice of high efficiency equipment/product over standard efficiency equipment/product in instances where the equipment did not receive a program incentive.
5. The open-ended response about why customers with eligible projects do not receive an incentive supported that the non-incented high efficiency installations can be considered spillover.

Sampled trade allies who do not pass one of the above screening criteria do not qualify for spillover and may be skipped out of the rest of the spillover module.

To quantify spillover for each sampled trade ally, the survey collects information on the percentage of the trade ally's total equipment installations/sales (in terms of projects or measures) that was (1) standard efficiency, (2) high efficiency that DID receive a program incentive, and (3) high efficiency that DID NOT receive a program incentive. Based on these responses, the share of a trade ally's high efficiency installations/sales that received an incentive can be calculated as follows:

$$\textit{\% of TA's High Efficiency Equipment that Received Incentive} = \frac{\textit{\% High efficiency that DID receive a program incentive (2)}}{\textit{\% High efficiency that DID receive a program incentive (2) + \% High efficiency that did NOT receive a program incentive (3)}}$$

With this data, and the trade ally's savings from the program tracking database, the following equation is used to calculate the savings of high efficiency equipment that did not receive an incentive:

$$\textit{Savings of Non-Incented High Efficiency Equipment} = \left(\frac{\textit{Savings from Program Database}}{\textit{\% of TA's High Efficiency Equipment that Received Incentive}} - \textit{Savings from Program Database} \right) * \textit{Size Adjustment}$$

The last term in the above equation is a size adjustment that accounts for the possibility that savings from non-incented projects/measures might be different from incented ones. Information on the relative size of incented versus non-incented projects/measures is also collected in the survey.

Using this approach, spillover savings are considered to be equal to the savings of non-incented, high efficiency equipment/products, as calculated in the equation above. To compute the program spillover percentage for active trade allies, the following steps are used:

1. **Develop the spillover ratio for sampled trade allies** by summing their spillover savings and dividing this total by the program-tracked savings associated with the sampled trade allies.
2. **Develop spillover savings for the population of active trade allies** by applying the spillover ratio from Step 1 to all program savings associated with a trade ally (whether a survey respondent or not).
3. **Develop the overall spillover ratio for active trade allies** by dividing the trade ally spillover estimate from Step 2 by total program savings (whether associated with a trade ally or not).

5.2.1.2 Midstream Programs

Similar to downstream programs, surveys can be used to ask active trade allies in midstream programs if the program influenced their sales of high-efficiency equipment to participating or nonparticipating customers and to quantify the program's impact on their high-efficiency sales. To assess if a sampled midstream trade ally created spillover, the following screening criteria are recommended (the order of these may be adjusted by the evaluator):

1. The percentage of the trade ally's sales that are high efficiency and/or the total volume of high efficiency sales increased since the trade ally became exposed to the program.
2. The trade ally sold at least some high efficiency equipment or products during the evaluation period that did not receive an incentive.
3. The trade ally's recommendation, marketing, or equipment/product stocking or placement was influential in the customers' choice of high efficiency equipment/product over standard efficiency equipment/product in instances where the equipment did not receive a program incentive.

Sampled trade allies who do not pass one of the above screening criteria do not qualify for spillover and may be skipped out of the rest of the spillover module.

To quantify spillover for each sampled midstream trade ally, the survey collects information on the percentage of the trade ally's total equipment sales (in terms of projects or measures) that was (1) standard efficiency, (2) high efficiency that DID receive a program incentive, and (3) high efficiency that DID NOT receive a program incentive.

Based on these responses, the share of a trade ally's high efficiency sales that received an incentive can be calculated as follows:

$$\textit{\% of TA's High Efficiency Sales that Received Incentive} = \frac{\textit{\% High efficiency that DID receive a program incentive}}{\textit{\% High efficiency that DID receive a program incentive + \% High efficiency that did NOT receive a program incentive}}$$

Through additional survey questions,[78] the evaluator should develop an attribution percentage, i.e., the proportion of non-incented high efficiency projects or measures that are attributable to the program. With this data, and the trade ally's savings from the program tracking database, the following equation is used to calculate the trade ally's spillover savings:

$$\textit{Spillover Savings} = \left(\frac{\textit{Savings from Program Database}}{\textit{\% of TA's High Efficiency Sales that Received Incentive}} - \textit{Savings from Program Database}\right) * \textit{Size Adjustment (if applicable)}$$

The last term in the above equation is a size adjustment that accounts for the possibility that savings from non-incented projects/measures might be different from incented ones. Information on the relative size of average energy savings of incented versus non-incented projects/measures is also collected in the survey if the evaluator expects a potential difference in relative size.

To compute the program spillover percentage for active midstream trade allies, the following steps are used:

1. **Develop the spillover ratio for sampled trade allies** by summing their spillover savings and dividing this total by the program-tracked savings associated with the sampled trade allies.
2. **Develop spillover savings for the population of active trade allies** by applying the spillover ratio from Step 1 to all program savings associated with a trade ally (whether a survey respondent or not).
3. **Develop the overall spillover ratio for active trade allies** by dividing the trade ally spillover estimate from Step 2 by total program savings (whether associated with a trade ally or not).

5.2.2 Spillover from Inactive Trade Allies

Inactive trade allies may create spillover if they are exposed to the program but do not directly facilitate program participation, i.e., they did not complete any projects through the program during the evaluation period. Rather, they promote and stock higher-efficiency equipment due to the influence of the program on the market.

Surveys can be used to ask inactive trade allies if the program influenced their sales of high-efficiency equipment to participating or nonparticipating customers and to quantify the program's impact on their high-efficiency sales. The general questions take the following form:

- Q.1: How many <measures> did you sell in <utility>'s service territory in <period>?
- Q.2: How many of them were <efficiency level> or higher?
- Q.3: Had the <program> not existed, how many <measures> of <efficiency level> or higher do you think you would have sold in <utility>'s service territory?

Evaluators should attempt to allow trade allies sufficient time to collect specific data (e.g., by sending information ahead of the interview or conducting additional follow-up; this might require providing incentives as inactive trade allies tend to be hard-to-reach) and not rely on "guesses" to respond. Additional questions should be included to document how the program influenced sales of additional energy efficient measures and why these measures did not receive an incentive.

For programs that offer a number of different measures, the evaluator should select and ask about a small number

[78] As some trade allies may find it difficult to directly quantify the program's attribution effect on non-program sales, the evaluator may need to use a series of questions to guide the trade ally to provide an estimate of the overall attribution. Questions may include asking about what factors influence sales of non-program efficient equipment/products and how the program influences individual factors to provide context for an overall attribution estimate.

of measures or measure groups that are most likely to generate spillover, e.g., the program's highest impact measures. The selection of trade allies to include in this research will depend on the measures selected, e.g., if the highest impact measures are lighting measures, the population of trade allies from which to sample should be lighting contractors.

The following steps are used to calculate the spillover percentage for inactive trade allies:

1. **Develop the total number of spillover units for each trade ally** by computing the difference between the total reported number of high-efficiency units sold and the number that would have been sold in the program's absence, for each measure type.
2. **Develop the total spillover savings for each trade ally** by multiplying the trade ally's total number of spillover units (from Step 1) by the average gross unit savings, for each measure type.
3. **Compute the total spillover savings for the program period** by summing the spillover savings from all sampled trade allies (from Step 2) and multiplying this sum by the ratio of the population of inactive trade allies to the sample, for each end-use.
4. **Compute the program spillover percentage** by summing the spillover savings for all end-uses (from Step 3) and dividing this sum by program gross savings.

It should be noted that the methodology for inactive trade allies requires the evaluator to quantify the number of trade allies in the population. Depending on which types of inactive trade allies are targeted by the research, determining the size of the population may be challenging and may lead to uncertainty in the results. When targeting trade allies that are on the utility's trade ally list (but are not active) or those who have been active in the past but have dropped out, program records allow for accurate estimation of the population size. However, when targeting trade allies that have never been active in the program and were never on the utility's trade ally list, secondary market data is required to develop estimates of population size. The evaluator should carefully document the target population for any inactive trade ally research, data sources used to quantify the population size, and any uncertainty associated with their estimates.

5.3 Consumption Data Analysis Protocol

This protocol refers to impact analyses that use consumption data from customer's monthly bills (commonly referred to as billing analysis) or AMI meter reads[79] to estimate program energy savings. This protocol discusses different consumption data methods and where they fall on the NTG spectrum with respect to participant spillover, nonparticipant spillover, and free ridership; this has implications for whether a NTGR needs to be applied after the consumption data analysis estimate is obtained in order to achieve an estimate of net savings. Decisions of whether to apply a NTGR after conducting a consumption data analysis should be made by the evaluator on a case-by-case basis taking into account the guidelines of this protocol for when these methods are net, gross, or somewhere in between.[80] The remainder of this section discusses NTG for various consumption data analysis methods and then goes through some details of the various analysis methods.

In general, consumption data analysis methods split into two approaches. One approach is to use a comparison group in a randomized control treatment (RCT) design, a random encouragement design (RED) or a quasi-experimental design. These comparison group approaches can, under the right circumstances, be used to directly estimate net savings eliminating the need for a NTGR adjustment. A second approach is to estimate savings without a comparison group (for example, using a pre/post regression model for program participants). Approaches without a comparison group produce gross savings and must be adjusted by a NTGR to achieve net savings.

In consumption data analysis, energy consumption of the treatment and control groups can be appropriately

[79] Benefits of using AMI data can include: having more observations per customer, which may improve model precision; obviating concerns over billing periods with differing numbers of days; and, for hourly models, providing the ability to observe intraday load shifting in addition to energy savings.

[80] For example, it is generally accepted that programs for income qualified customers have little to no free ridership as these customers are unlikely to install the measures without the incentive of the program. For specific guidance on income qualified programs see Section 0.

compared through a regression analysis, using time-series observations on the usage of individual customers in the treatment and comparison groups during the pre- and post-treatment periods. Due to the combined time-series/cross-section structure of such data sets, panel regression techniques can be used.[81]

In general, consumption data analysis methods are best suited to the following situations:

1. When the expected net savings per participant (i.e., the effect size) are large or when large participant/nonparticipant sample sizes are possible.
2. When the program can be designed using a randomized controlled trial (see Section 0).
3. Programs where nonparticipant spillover is expected to be trivial within the comparison group.
4. Cases where self-selection bias can be effectively controlled for.

5.3.1 Consumption Data Analysis and NTG

Different consumption data analysis methods produce different savings estimates in terms of the NTG spectrum, as summarized in Table 5-2. These methods will always yield gross savings with respect to nonparticipant spillover and net savings with respect to participant spillover. However, the savings estimates may be net, gross, or somewhere in between with respect to free ridership, depending on the evaluation technique.

Table 5-3. NTG Summary for Consumption Data Analysis

Consumption Data Analysis Method	Free Ridership	Participant Spillover*	Nonparticipant Spillover**
Randomized Controlled Trial (RCT)	✓	✓	§
Random Encouragement Design			
No Instrumental Variable (IV)	†	✓	§
IV	†	✓	§
IV w/ Inverse Mills Ratio (IMR)	†***	✓	§
Quasi-Experimental Design (QED) ****			
Matching			
To Nonparticipants	†*****	✓	§
To Prior or Future Participants	§	✓	§
Regression Discontinuity (RD)	✓	✓	§
Variation-in-Adoption (VIA)	§	✓	§
Without a Comparison Group	§	✓	§

§ Indicates not accounted for (gross)
✓ Indicates fully accounted for (net)
† Indicates partially accounted for (between net and gross)
* Participant spillover within the analysis timeframe in the same building and fuel type is captured. Other sources of participant spillover may not be captured. See the subsection on participant spillover below for details.
** Nonparticipant spillover is not captured as a positive in consumption data analysis and may actually reduce the estimate of savings if it occurs within the comparison group. See the subsection on nonparticipant spillover below for details.
***This method has been tested in simulation but needs further use in practice.

[81] "Panel" refers to the data set consisting of time-series observations on energy consumption of a cross-section of treatment and control customers. Panel estimation techniques refer to the model's inclusion of terms that control for individual customer heterogeneity (e.g., customer fixed effects or a lagged dependent variable), and cluster-robust standard errors, which can accommodate differing error variances across customers and an intracustomer correlation of errors.

**** Note that this is a non-exhaustive list of QED evaluation techniques.
***** As noted in first few paragraphs of Section 0, these comparison group approaches can, under the right circumstances, be used to produce an of estimate net savings, eliminating the need for a NTGR adjustment (see Goldberg et al., 2017).

When consumption data analysis methods are being used to update the TRM, the update should explicitly state how a NTGR should be applied to the given measure or program in the future. The language used should consider different program delivery mechanisms (which often have different NTG values) and how stable the NTG value is likely to be over time (thus allowing for consideration of how frequently it should be updated).

5.3.2 Nonparticipant Spillover

Nonparticipant spillover is never captured by consumption data analysis, making these savings estimates gross with respect to nonparticipant spillover (i.e., nonparticipant spillover is not accounted for by the estimate directly from the consumption data analysis without further adjustment). To the extent that nonparticipant spillover occurs in the comparison group being used for evaluation, the effect of the program may be underestimated as the difference between the participant group and the comparison group is decreased by the amount of nonparticipant spillover. If nonparticipant spillover is expected to be large (based on the best research available or given the program's logic model) and occur within the evaluation comparison group, that may be a reason to use other methods for evaluating savings. If a billing analysis is done in these cases, a traditional nonparticipant spillover analysis (using techniques like nonparticipant surveys or interviews) should be used to help quantify this effect (these analyses are discussed in various subsections of Chapter 4 of this protocol). Within the comparison group, it can also be difficult to distinguish the effects of nonparticipant spillover, free ridership, and market transformation as all of these effects increase uptake of a measure without going through the program among the nonparticipant group.

In cases where nonparticipant spillover is not expected to occur in the comparison group but may occur in the broader population (for example, if we go from a pilot evaluation where measures were restricted among the comparison group to a full program deployment), adjustments for nonparticipant spillover (or justification for why there is no nonparticipant spillover) should be made as appropriate on a program-by-program basis.

5.3.3 Participant Spillover

Participant spillover is captured by consumption data analysis, making these savings estimates net with respect to participant spillover (i.e., participant spillover is accounted for by the estimate directly from the consumption data analysis without further adjustment). This occurs because consumption data analysis measures all changes in participant usage (captured by the utility billing system or AMI meter reads) regardless of whether the changes are related to the program. A few caveats apply:

1. Consumption data analysis does not capture participant spillover that occurs outside the home or business being analyzed. For example, spillover at a participant's vacation home or spillover at other facilities owned by the same firm.
2. Consumption data analysis does not capture participant spillover that occurs in a different fuel type. For example, if the analysis is done on electric data but there is participant spillover into natural gas.
3. Consumption data analysis does not capture participant spillover that occurs outside the analysis period (typically a one-year period).

If these sources of participant spillover that are not captured are expected to be large (based on the best research available or given the program's logic model), adjustments or additional analysis to capture these types of participant spillover may be required.

5.3.4 Free Ridership

With respect to free ridership, consumption data analysis can produce savings estimates that are net, gross, or somewhere in between (i.e., free ridership can be fully, not at all, or partially accounted for by the estimate directly from the consumption data analysis without further adjustment). Where they fall depends on whether the comparison group accounts for (or nets outs) free ridership in the estimation. For a summary of where each method falls see Table 5-3 above.

Methods that yield gross savings estimates with respect to free ridership have no comparison group or have a comparison group that is made up of other (prior or future) participants. In these cases, a free ridership adjustment (or justification of why there is no free ridership) is necessary. These methods include:

- Matching to older or newer participants[82]
- Variation-in-adoption (VIA)[83]
- Any method without a comparison group

Methods that yield net savings estimates with respect to free ridership have a nonparticipant comparison group that has the same level of free ridership as the participants. In these cases, the comparison group is engaging in energy efficiency activities at the same rate as the participant group would have without the program. This nets out the free ridership and means no free ridership adjustment is necessary. These methods include:

- Randomized controlled trial (RCT)
- Regression discontinuity (RD)
- Random encouragement design (RED) under at least one of the following conditions:
    - Analysis is done using instrumental variables with an inverse mills ratio[84]
    - Designs where only the encouraged group can join the program (and as such the participants who join the program include only compliers and not always takers[85])
    - There is no relationship between how much energy a customer will save by participating and their inclination to participate

Methods where there is a nonparticipant comparison group that is expected to have a different level of naturally occurring adoption than the participant group can result in savings estimates that fall somewhere between net and gross with respect to free ridership. For example, a group of participants would be expected to be comprised of more natural adopters than a group of nonparticipants who never joined the program. These methods include:

- RED (in situations not covered by the previous list showing when RED is net)
- Matching to nonparticipants

In these cases, it is up to the evaluator to decide whether an estimate is most appropriately considered net or gross on an analysis-by-analysis basis. Some guidelines include:

- Measures where instant upstream rebates exist for a large portion of the market are likely gross as there should be very few customers who got the measure in the nonparticipant group
- Measures for income qualified customers are typically considered net as these customers are unlikely to install the measures without the incentive of the program

In some cases, evaluators may be able to implement techniques when using a nonparticipant comparison group such that the savings are sufficiently close to net and do not require further net to gross adjustment. One example of these techniques is the IV-IMR method proposed in Goldberg et. al. (2017). The UMP Chapter 21 (Violette and Rathbun, 2017) also has some discussion of getting net savings estimates using these approaches, although UMP Chapter 8 (Agnew and Goldberg 2017) should be reviewed in conjunction as it is more specific to consumption data methods. However, these techniques often require customer characteristic data that is not readily available to

[82] Except in the case of income qualified programs where the use of future participants can produce an estimate of net savings. For specific guidance on income qualified programs see Section 0.

[83] See Harding and Hsiaw (2013). This is a distinct method from the UMP Chapter 8 (Agnew and Goldberg, 2017) pooled fixed effects approach which can be estimated with multiple years of participants. VIA hinges on rolling enrollment and in essence uses each participant as a control and a treatment customer through time. The Chapter 8 pooled fixed effects approach uses participants from an earlier time period as a comparison group for participants from a later time period.

[84] For details see: Goldberg, M.; Agnew, K.; Train, K.; Fowlie, M. (2017). *Mitigating Self-Selection Bias in Billing Analysis for Impact Evaluation.* Pacific Gas and Electric Company. CALMAC Study ID PGE0401.01. <http://www.calmac.org/publications/Mitigating_Self_Selection_Bias_in_Bill_Analysis_8.4.17.pdf>

[85] See Section 5.

evaluators and some of them needed to be further tested beyond theoretical simulations.

5.3.5 Consumption Data Analysis Designs with a Comparison Group

This section discusses descriptions of and considerations for estimating savings via consumption data analysis designs with a comparison group. Although the ideas of net and gross savings are touched upon, the full discussion on whether each of these methods produce net or gross savings and under what circumstances is in Section 0.

5.3.5.1 Randomized Controlled Trials

In a randomized controlled trial (RCT) design, evaluators (and sometimes implementation contractors) randomly assign sampled members of a population of interest to a treatment group or a control group. Among the benefits offered by an RCT—when properly applied—is that it produces net savings estimates by netting out free ridership.[86] The evaluation of a program must be designed and implemented this way from the outset; it is not possible for an evaluation team to apply RCT evaluation techniques after the program has been implemented if random assignment to treatment and control groups was not done before program launch. While such designs are rarely possible outside of Home Energy Report programs, one should not overlook the possibility of such designs in evaluating new pilot programs.

For some programs, evaluators must take a second step to ensure savings are not being double-counted, either counting savings being claimed by other programs or savings already credited to earlier program efforts (often called "legacy uplift"). Only net increases in participation in other programs should be considered in this uplift adjustment; changes to total savings do not need to be made based on decreases in participation in other programs.

5.3.5.2 Random Encouragement Designs

In a random encouragement design (RED), eligible customers are randomly assigned between an encouraged group (who receives incremental encouragement to join the program[87]) and a non-encouraged, or control, group (who does not receive the encouragement). Members of either group can join the program, but the encouraged group is expected to do so at a higher rate.[88] If the encouragement is not effective at driving the encouraged group into the program at a higher rate than the non-encouraged group then the evaluation design breaks down and other (likely quasi-experimental) methods will be needed to estimate program savings.

In an RED, both the encouraged and non-encouraged group are made up of the following:

1. Always takers – customers who will join the program with or without the encouragement
2. Compliers – customers who only join the program if they receive the encouragement
3. Never takers – customers who will never join the program, regardless of whether they receive the encouragement

In the non-encouraged group, the always takers can be distinguished from the compliers and never takers (they're the portion of the non-encouraged group who joins the program), but the compliers and never takers cannot be distinguished from one another (they're both observed not to join the program). In the encouraged group, the never takers can be distinguished from the always takers and compliers (they're the portion of the encouraged group who does not join the program), but the always takers and compliers cannot be distinguished from one another (they're both observed to join the program).

Like RCTs, REDs are a form of experimental design. An RED is known to give an unbiased estimate of net savings

[86] RCTs eliminate free rider bias because the random assignment of customers to treatment and control groups equally distributes such participants between the two. Due to differential attrition and random chance, small differences may occur between the distributions of free riders in the two groups for any given sample. Their expected values, however, will be identical, and in any case the size of any such discrepancies shrinks as sample size increases. Thus, this is only a potential concern for programs with unusually small numbers of participants.) Upon comparing the two groups' energy consumption, free riders' energy savings in the control group cancel out those in the treatment group, eliminating free rider bias.

[87] The encouragement could take many forms including targeted marketing or direct monetary incentives.

[88] This design does not preclude mass marketing of the program to all customers but relies on the encouragement being effective at driving the encouraged customers into the program at a higher rate than the non-encouraged customers.

(with respect to free ridership) for the compliers. Applying this savings to the always takers group requires some explanation of why it is likely to be accurate. Additionally, the RED design provides the average net savings per participant for those who participate because of the encouragement but otherwise would not (compliers). This is not necessarily the same as the net savings for the original program without extra encouragement. In particular, we would expect free-ridership to be lower among those who need extra encouragement. Thus, the RED might be expected to overstate net savings for the original program if free-ridership is present but would still provide useful information.

There are several methods for evaluating REDs using panel data including methods using instrumental variables (IVs) and the inverse mills ratio (IMR).[89]

5.3.5.3 Quasi-Experimental Designs

Where randomized assignments prove infeasible, quasi-experimental design (QED) evaluation methods can be substituted (although experimental designs are typically preferable when possible). Depending on the exact QED implemented, the savings may be net, gross, or somewhere in between with respect to the different pieces of a NTG adjustment (participant spillover, nonparticipant spillover, and free ridership). The specifics of net versus gross estimation are covered in Section 0, this subsection does not rehash this issue but rather describes estimation for a subset of QED methods.

Three quasi-experimental approaches are commonly used to evaluate behavior-based energy efficiency programs that cannot be constructed as experiments:[90]

- Regression discontinuity (RD)
- Variation-in-adoption (VIA)[91]
- Matched controls (MC)

All three rely on a nonrandom comparison group.

Regression Discontinuity. RD requires basing a program's eligibility on a continuous variable (e.g., customers' adjusted gross income falling below a cutoff value for them to qualify for the program). When this is true, the RD method assumes customers just beyond the cutoff likely will be very similar, on average, to those just inside of it. The method compares changes in energy usage for a group just outside of the eligible range to that of a group of participants just on the other side of the eligibility cutoff. The RD approach, however, is susceptible to an important weakness: misspecification of the regression functional form.[92]

Variation-in-Adoption. The VIA model applies only to program participants.[93] For this method, customers must sign

[89] See, for example:
Goldberg, M.; Agnew, K.; Train, K.; Fowlie, M. (2017). *Mitigating Self-Selection Bias in Billing Analysis for Impact Evaluation.* Pacific Gas and Electric Company. CALMAC Study ID PGE0401.01. <http://www.calmac.org/publications/Mitigating_Self_Selection_Bias_in_Bill_Analysis_8.4.17.pdf>
Fowlie, M.; Greenstone, M.; Wolfram, C. (2015). *Are the Non-Monetary Costs of Energy Efficiency Investments Large? Understanding Low Take-up of a Free Energy Efficiency Program*. American Economic Review: Papers and Proceedings 105(5): 201-204. < https://www.povertyactionlab.org/sites/default/files/publications/389_500%20Weatherization%20AER.pdf>

[90] There are many other types of QEDs that may be appropriate for evaluation, but these are some of the most commonly used for evaluation in IL.

[91] See Harding and Hsiaw (2013). This is a distinct method from the UMP Chapter 8 (Agnew and Goldberg, 2017) pooled fixed effects approach which can be estimated with multiple years of participants. VIA hinges on rolling enrollment and in essence uses each participant as a control and a treatment customer through time. The Chapter 8 pooled fixed effects approach using participants from an earlier time period as a comparison group for participants from a later time period. The Chapter 8 pooled fixed effects method is discussed in Section 0.

[92] The most common misspecifications are: mistaking a nonlinear relationship for a discontinuity; and failing to recognize potential interactions between assignments and the treatment studied. See W.R. Shadish, T.D. Cook and D.T. Campbell, *Experimental and Quasi-Experimental Designs for Generalized Causal Inference*, Wadsworth 2002, pp. 229-238.

[93] Harding, M. and Hsiaw, A. 2013. *Goal Setting and Energy Conservation* Available at: http://people.duke.edu/~mch55/resources/Harding_Goals.pdf.

up for the program on a rolling basis. VIA takes advantage of its enrollees' differential timing to compare energy usage of customers opting in to that of customers not yet opting in (but doing so later). The method relies on an assumption that, in any given month, customers that soon opt in have similar characteristics to those who have enrolled, both in observable and unobservable characteristics. For this assumption to prove valid, customers must decide to opt into the program at different times for essentially random reasons (e.g., influenced only by marketing exposure and program awareness).[94] In particular, the decision to opt in should not relate to observable or unobservable household characteristics.[95]

Matched Controls. MC creates a control group by matching each treatment customer to the most similar nonparticipant customer available on the basis of exogenous covariates from the pre-enrollment period known to highly correlate with post-enrollment usage.[96] The covariate most likely to correlate with post-enrollment energy usage in a given time period is customer energy usage during the same period of the preceding year, but other observable factors may be used when available. Implementing MC requires customer usage data for the year preceding all opt-in customers' decisions to participate in the program, along with a large group of nonparticipants who can be assumed to be similar to opt-in customers, aside from their program participation status. Whenever possible, the pool of potential matches should be drawn from the same geography, customer class, and rate category as the participants.

Another option is to pull the nonparticipants from a group of prior or future participants in the program (sometimes referred to as the cohort design[97]). These groups are similar to current participants since we know that they also join the program at an earlier or future date, significantly mitigating the issue of self-selection bias (wherein, customers who join the program are different from those who do not in unobservable ways).[98] However, using this design can significantly decrease the number of participants for analysis and the size of the potential matching group. It can also require the evaluator to delay the analysis if more recent participants are being used as the comparison group.[99]

The MC method involves identifying a nonparticipant customer whose energy usage closely matches that of a program participant in the months preceding the participant's enrollment in the program. The logic inherent in this approach is: if the analyst finds a set of nonparticipants who, on average, are the same as participants regarding energy consumption before program enrollment, these matches will provide a good counterfactual estimate of how much energy participants would have used in the program's absence.

The MC approach does present a main weakness: it can only identify matches based on observable customer characteristics, which leaves open the exclusion of the possible influence of relevant unobservable variables. While factors other than pre-enrollment energy usage plausibly could be used (e.g., household income, demographics, geographic location) in the matching process to address relevant unobservable characteristics (e.g., attitudes toward

[94] This differs from an RCT with a recruit-and-delay design, in which customers do not choose when to opt in, but instead are randomly assigned different times to opt in, and from an RCT with a recruit-and-deny design, where customers are randomly denied access to the program.

[95] As the validity of the VIA method depends on this assumption, it should be empirically tested to the extent possible. If program marketing is punctuated and dates of marketing exposure are known, it is possible to test whether household enrollment in any particular month is driven by marketing activity, as opposed to observed household characteristics or unobserved heterogeneity. A test of whether the energy usage of households before they opt in differs from households that opt in during any particular month as opposed to another month is built into the VIA regression model's functional form. See Harding and Hsiaw, op. cit., for details.

[96] See Daniel E. Ho, Kosuke Imai, Gary King, and Elizabeth Stuart, 2007, "Matching as Nonparametric Preprocessing for Reducing Model Dependence in Parametric Causal Inference." *Political Analysis* 15(3): 199-236.

[97] See W.R. Shadish, T.D. Cook and D.T. Campbell. (202). *Experimental and Quasi-Experimental Designs for Generalized Causal Inference*. New York: Houghton Mifflin Company, pp. 148-153

[98] Though there could still be a selection issue based on when customers choose to join the program. As with VIA, the assumption is that the timing of participation is basically random.

[99] The cohort design has also been used, under certain conditions, to control for exogenous factors when estimating gross savings. See Agnew, K. and M. Goldberg. (2017). Whole Building Retrofit with Consumption Data Analysis Evaluation Protocol: Chapter 8 of the Uniform Methods Project, National Renewable Energy Laboratory.

energy conservation and environmental concerns), this assumption cannot be directly tested.[100]

There is a special case of MC called propensity-score matching. This develops a binary choice (logistic regression) model to predict the probability that a customer will opt into the program, and then, for a comparison group. The logistic regression reduces each household's set of covariates to a single propensity score. Nonparticipants are then matched to participants based on their propensity scores. This functions well if observable variables used to calculate the propensity score sufficiently correlate with relevant unobservable variables to explain differences between treatment and control customers that cannot be explained by matching on observable variables. With most evaluations of energy efficiency programs, however, little (if any) data are available on nonparticipating customers other than their energy usage. In some cases, the demographic data necessary to estimate these models can be obtained from providers such as Experian and assigned to each participant and nonparticipant.

Self-Selection Bias and QED. Self-selection bias due to observable and unobservable variables is always a possibility with QEDs. One can collect as much information as possible on both participants and members of the comparison group and include them as covariates in the regression model, but there may still be self-selection bias related to unobservable variables. Several techniques have been developed to help mitigate it. Efforts to address the biasing effects of *unobserved* differences using Inverse Mills Ratios began at least as early as the late 1980s. Since then, Train (1993) and Goldberg and Train (1995), using simulated datasets, demonstrated that failing to correct for self-selection can overestimate net savings, but that there are effective strategies to reduce this bias substantially.

One approach is to calculate and enter the propensity score, based on observable variables, as an additional covariate into the regression model. Of course, the most difficult issue to address is the differences between participants and nonparticipants that are unobserved and unobservable. To mitigate both overt and hidden bias, a variety of approaches that attempt to take advantage of recent developments in statistics and econometrics are available:

- Sample selection models (e.g., Heckman's two-step estimator (1978, 1979); treatment effect model (Green, 2003); instrumental variables estimator (Wooldridge, 2002)
- The propensity score matching model (Rosenbaum and Rubin, 1983, 1985; Hansen and Klopfer, 2006; Guo and Fraser, 2014)[101]
- Matching estimators and synthetic controls (Abadie and Imbens, 2002, 2006)
- Instrumental variables approach with the predicted probability of participation serving as the instrumental variable and the inclusion of an Inverse Mills Ratio (IMR) (Goldberg et al., 2017)

Another issue that should be considered is that, when using a comparison group in a QED, the composition of the comparison group needs to be carefully considered.[102,103] For example, simply selecting a random sample of nonparticipants from the general nonparticipant population could result in an estimate of savings that is somewhere between net and gross, thus overestimating net savings. For a single-measure residential program like an air conditioner (AC) replacement program, the eligible population is the population of customers who have purchased a new air conditioner. That is, part of the eligible population appropriate to a net effects comparison group would be those who purchased and installed some air conditioner, whether efficient or not. Simply selecting from the general residential population would include households with no air conditioner, those with older ACs of varying vintages, those with new standard efficient ACs and those with new program-qualified ACs. The results would be virtually uninterpretable. Of course, for more complex multi-measure programs, finding the appropriate comparison group is far more challenging.

[100] Such secondary, observable characteristics are rarely available to evaluators of energy efficiency programs, except for geographic location (e.g., postal zone of customer premise).

[101] Note that propensity scores cannot remove hidden biases except to the extent that unmeasured variables are correlated with the measured covariates used to compute the propensity score

[102] See Agnew at al., Section 8.1.3 (The Importance of Measures Applicability)

[103] Katherine Randazzo, Richard Ridge and Seth Wayland. Evaluating Whole-Building Programs: It is harder and easier than you think! Presented at the International Energy Program Evaluation Conference in August 2017.

5.3.6 Consumption Data Analysis Designs without a Comparison Group

Although less common, consumption data methods can also be used to estimate savings without the use of a comparison group. These methods typically estimate gross savings, and net savings are found by multiplying gross savings by a separately estimated NTGR. There are basically two types of pre/post models to estimate gross savings:

- the pooled participant-only linear fixed-effects approach
- site-specific regression models

In both modeling approaches, exogenous factors must be controlled for.[104]

Pooled Approach. The pooled approach addresses exogenous change without the inclusion of a separate comparison group. In this model, participants who received a measure installation during a certain time interval serve as a steady-state comparison for other participants in each other time interval. Almost all observation points include premises that are still in their pre-installation period and premises that are in their post-installation period, so the effect of post- versus pre- is estimated to control for exogenous trends. Note that if changes at the site that affect energy use are not or cannot be explicitly modelled the estimated gross savings will be biased. This method is typically used in analysis of residential and small (and occasionally for large) commercial programs.

Site Specific Regression Models. This approach involves the estimation of site-specific regression models to estimate savings. This method is often used for large commercial and industrial customers or in other situations where it is difficult to identify an adequate comparison group (for example, in evaluation of Strategic Energy Management programs). In these cases, single customer regressions are typically run as a time series without a cross-section of customers.

Note that both the pooled approach and the site-specific approach and the conditions that must be met before using them are discussed in Agnew and Goldberg (2017).

5.3.7 Program Implementation and Consumption Data Analysis

The approach the evaluation can use to estimate net savings is greatly dependent on the design of the program and the size of the expected savings (i.e., the signal-to-noise ratio).

RCT and RED: These designs must be integral to a program's implementation. Without the ability to randomly assign customers to the control and treatment groups (or at least randomly encourage customers to participate in a program), the ability of the design to yield unambiguous estimates of net impacts is compromised. Evaluators often help design how a program is implemented. However, if they not involved at the outset, they cannot carefully review choices made by the implementation team. RCT and RED designs are difficult to perform well within the commercial and industrial sectors due to a low signal-to-noise ratio. One solution for these two sectors is to increase the sample size but this is not always feasible.

QED: A QED may be designed after a program has been implemented. It relies on determination of an equivalent comparison group, which is often chosen based on energy use and other variables, if available. QED is also difficult to perform well within the commercial and industrial sectors due to a low signal-to-noise ratio. One solution for these two sectors is to increase the sample size but this is not always feasible.[105]

Methods without a Comparison Group: These methods can also be implemented by the evaluator after the program has been designed. They are most appropriate in situations where it is difficult to construct an appropriate comparison group.

For any kind of evaluation design, evaluators may also analyze the data to help understand the savings within specific segments if sufficient information and data points are available.

[104] Exogenous factors include non-program-related effects due to the economy and other factors affecting energy consumption.

[105] A power analysis can be undertaken before the actual analysis to determine whether the sample size available is likely to be large enough to produce statistically significant savings at the desired confidence level.

5.4 Midstream Free-Ridership Protocol[106]

Typical energy efficiency programs offer incentives to end-use customers to purchase more efficient equipment. These can be referred to as "downstream" incentives, or downstream programs. Moving up the supply chain, the next entities are distributors, contractors, and design professionals. Programs aimed at influencing these market actors are referred to as "midstream" programs. "Upstream" programs target manufacturers and potentially retailers.

5.4.1 Using This Protocol

The methods described in this section should be applied for estimating NTGRs for midstream programs in which the incentives are paid directly to distributors who have the option of sharing some or all of these incentives with the end-use customers in the form of price reductions. This midstream protocol can be used for estimating NTGRs for both residential and non-residential midstream programs that focus on distributors.[107] As discussed in further detail later in this section, programs of this type are designed to influence the behavior of distributors, and indirectly end-users, and intermediaries such as contractors, installers, or design professionals(to various degrees).[108]

As a result, in midstream programs where it is believed that multiple parties are aware of the utility intervention, it is desirable for evaluators to conduct research that produces multiple estimates of free ridership from different perspectives, and to combine these estimates using guidance provided in Section 5.1: Combining Participant and

[106] Note that the method for assessing trade ally spillover is included in Section 5.2.

[107] See Section 4.3 for a description of an approach for calculating NTG specifically for Residential Upstream Lighting programs.

[108] Note that the Illinois TRM does not currently prescribe a specific method for assessing free ridership from a trade ally perspective. Consistent with Section **Error! Reference source not found.**, until such a prescribed methodology becomes available, evaluators should coordinate on survey design and calculation algorithms for trade ally free-ridership estimation.

Trade Ally Free Ridership Scores to estimate a NTGR that is inclusive of multiple perspectives.[109]

In these cases, care should be taken to design an evaluation approach that most appropriately reflects the theory of program influence and selects perspectives to research free-ridership commensurate with program theory. For example, in many midstream HVAC program models, intermediaries (contractors/installers) have an influential role in the sales process with end-use customers, and to the extent that program design attempts to influence intermediary behavior as well as distributor and end-user behavior, research with these actors may be appropriate. Conversely, in other midstream program models, intermediaries may not be a target for program activity and/or may not play an influential role in the sales process, in which case research with these actors would not be appropriate.

All midstream programs should collect contact information for participating distributors and make it available to evaluators. Midstream programs may or may not collect information for other actors such as end-use customers and/or intermediaries. In cases where midstream programs do not collect customer information, end-user research will generally not be feasible, and free ridership estimates will not be able to include an end-user perspective on free-ridership. In cases where midstream programs do not collect intermediary information, intermediary research may still be feasible, but will require care in order to define an appropriate sample that accurately represents the pool of intermediaries relevant to the program. For example, some midstream programs may not track installing contractors but may maintain a list of qualified program allies who would be expected to complete a significant share of installations receiving program incentives.

If evaluation constraints do not allow for high quality research to be conducted from multiple perspectives, it is likely preferable to conduct high quality research from only one perspective rather than lower quality (e.g., minimal sample size) research from multiple perspectives, and the evaluator may choose to utilize only one approach without it being considered a divergence from the IL-NTG Methods. In this case, the evaluator should carefully consider the specific design and intent of a given program when choosing the appropriate protocol(s) for evaluation and must document the rationale for their decision in the evaluation plan.

Ultimately, the protocol(s) to be used for a given program is defined in Table 3-1 and Table 4-1. If the design of a given program changes significantly, then it may mean that the NTG protocol listed for that program in Table 3-1 or Table 4-1 is no longer appropriate. In addition, the evaluator may determine that the defined customer or distributor NTG algorithms need to be substantially modified to accommodate the specific design of a midstream program. If the evaluator chooses to use an alternative method or approach to estimate the NTG, the evaluator should follow the procedures outlined in Section 1.4: Diverging from the IL-NTG Methods. For new programs, the choice of protocol(s) will be ultimately at the discretion of the evaluator.

Midstream Influence Pathways

Knowing that they will receive an incentive for selling high efficiency units, distributors may choose to increase their stock of high efficiency units, and/or to upsell high efficiency units to contractors. Distributors may also choose to offer training sessions or marketing campaigns aimed at engineers, architects, and contractors to increase awareness of these high efficiency units. As a result of the program's actions:

- Contractors/customers may be more likely to purchase high efficiency units because they are in stock,
- Contractors/customers may be more likely to purchase high efficiency equipment because the distributor upsold these units,
- Contractors/customers may be more likely to purchase high efficiency units because the incremental cost is lower than it would have been without the incentive (assuming the distributor uses the incentive to reduce the price of the equipment), and
- Design professionals and contractors may be more likely to specify or recommend high efficiency units because they are more aware or more familiar with these options.

The expected overall outcome is that a greater proportion of customer purchases will be high efficiency units. As

[109] In cases where midstream programs require distributors to pass the entire incentive to a customer and collect customer information, it is still likely that the program is affecting distributor behavior, and distributor research is still valuable.

distributors sell more high efficiency units, manufacturers will respond by producing more high efficiency equipment. Ultimately, the overall market in a utility's service territory will become more efficient than it otherwise would have been, or it will achieve this efficiency sooner than if no intervention had occurred.

To assess impacts from this type of program, the evaluator needs to determine if the distributor changed their practices in a way that ultimately influenced the customer's buying decision. Assessing the influence of the program involves conducting in-depth interviews with participating distributors and asking them how they would have behaved – or how outcomes would have differed – in the absence of the program. While interviews with others, such as contractors and design professionals, can also be conducted in order to develop a more complete understanding of the influence of the program, the focus of the protocol in Section 0below is on the distributor interviews.

For estimating program influence from other perspectives (e.g., contractors, end users, etc.), evaluators should use the protocols described in sections 3.1.1: Core Non-Residential Free Ridership Protocol and 4.4.1: Residential Prescriptive Rebate (With No Audit) Protocol, as appropriate.

To ensure that the midstream NTGR approach covers all avenues of program influence, one should develop a logic model based on discussions with utility program staff, implementer staff, and a general review of midstream programs. The midstream NTGR approach recommended here is designed to be flexible, as the midstream incentives may be impacting distributors' businesses in one of many ways—including via changes in stocking, upselling, price reduction, etc. Ultimately, the midstream program should be given credit for influence via any of these causal pathways. Note that a midstream program might have longer-term impacts that are not immediately measurable. Such longer-term impacts manifest as "market effects," which signify a transformation in the underlying structure and functioning of the market. This midstream protocol does not address the measurement of such market effects.

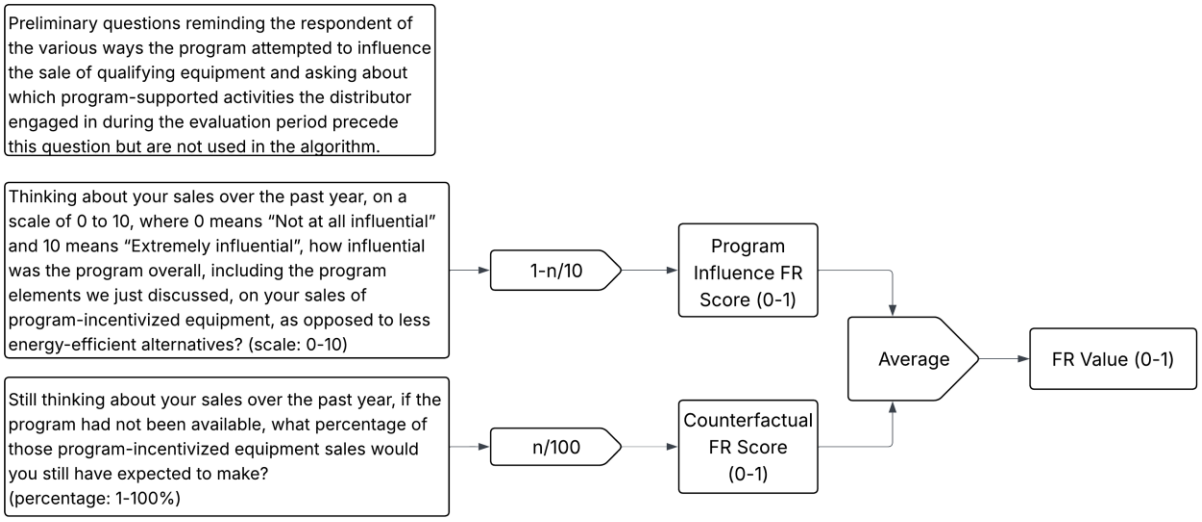
5.4.2 Distributor Free Ridership Estimation Methodology

This methodology uses two indicators of free ridership:

- Program Influence (PI) FR Score, and
- Counterfactual (CF) FR Score

These scores are then averaged to arrive at a final free ridership value for each interviewed distributor. The algorithm shown in Figure 5-1 can be used to calculate the free-ridership. The resulting distributor-level NTGR values should be weighted proportionately to the ex post gross kWh savings contributed by each distributor.

Figure 5-1. Distributor Free Ridership Protocol



Distributor Practices

Before asking program influence and counterfactual questions, the evaluator should introduce the various ways the program attempts to influence the sale of program-qualified equipment (per the program theory/logic model) and ask questions about which program-supported activities the distributor has engaged in during the evaluation period. These questions serve two purposes: (1) they establish which of the potential causal pathways (or program factors) are relevant for each distributor, and (2) they help set up the following questions by making sure the distributor thinks about the program holistically.

Program-supported activities to encourage the sale of program-qualified equipment may include, but are not limited to, the following:

___ Upselling customers (e.g., contractors, installers, design professionals) to higher efficiency equipment

___ Conducting training workshops for customers

___ Using marketing materials or other promotional tools to promote program-qualified units

___ Reducing the prices of program-qualified units

___ Using program incentives to support program participation (e.g., SPIF or "Sales Performance Incentive Fund")

___ Discussing the benefits of program-qualified units with design professionals

___ Participating in roundtables and/or trainings (e.g., of sales staff)

Program Influence FR Score

The PI FR Score measures the overall influence of the program on the distributor's sales of program-qualified units instead of a less efficient alternative. It is developed based on a single question that asks the distributor to rate the overall importance or influence of the program on their *sales* of program-incentivized equipment in a given time period (which would align with the evaluation period, likely, the past year), using a scale from 0 to 10, with 0 being not at all important or influential and 10 being extremely important or influential. In other words, this question attempts to assess the influence of the program on distributors' sales volume. Depending on the specific midstream program, evaluators may decide to allow for responses to this question to be split by equipment type or end use.

Evaluators will calculate the PI FR Score for each respondent using the following equation:

$$Program\ Influence\ FR\ Score\ = 1 - \left(\frac{[Influence\ Rating]}{10}\right).$$

This score can range from 0 (no free ridership) to 1 (full free rider).

Counterfactual FR Score

The Counterfactual FR score also focuses on distributors' sales volume of program-incentivized equipment. As such, distributors will be asked to think about their sales of program-incentivized equipment (i.e., equipment for which they provided an incentive or discount) in a given time period[110] and indicate what percentage of those sales they would still have expected to make in the absence of the program. Depending on the specific midstream program, evaluators may decide to allow for responses to this question to be split by equipment type or end use.

Evaluators will calculate the CF FR Score for each respondent using the following equation:

$$Counterfactual\ FR\ Score\ = \left(\frac{[\%\ of\ Sales\ distributors\ still\ would\ have\ made\ ]}{100}\right).$$

This score can range from 0 (no free ridership) to 1 (full free rider).

Consistency Checks

Evaluators should perform the following consistency check that focuses on discrepancies between the Program Influence and Counterfactual FR scores. When triggered, evaluators will ask distributors to describe how the program did or did not influence their sales of program-incentivized equipment in the given time period. This consistency check is triggered when either of the following conditions is met:

$$Program\ Influence\ FR\ Score - Counterfactual\ FR\ Score \geq 0.4$$

OR

$$Counterfactual\ FR\ Score - Program\ Influence\ FR\ Score \geq 0.4$$

Additional consistency check questions to resolve identified inconsistencies remain optional, but may be used by the evaluator to resolve inconsistencies in real time if desirable. For example, if distributors indicate they would have sold a high proportion of program-incentivized equipment without the program (e.g., CF FR Score > 0.75), evaluators may ask distributors how they would have been able to achieve the number of sales without the financial assistance provided by the program.

Additional Questions

Evaluators may incorporate additional questions to gather more information about distributors' practices, such as their stocking and upselling practices. This information could be valuable to place free ridership results in context and inform future discussions about the Midstream FR protocol. Examples of additional questions are:

- Since you started participating in the program, have you increased the stocking or assortment of program-qualified equipment?
- How influential has the program been on your stocking decisions related to program-qualified equipment relative to your stocking practices before participating?
- What proportion of your stock is program-qualified equipment?
- What proportion of your stock would be program-qualified equipment if the program were not available?
- Thinking of the last year or so, if program-qualified equipment was not available, how long would it usually take to have it back in stock?
- How influential was the program in increasing your success rate when promoting program-incentivized equipment in the last year?
- How influential was the program in how often you tried to promote program-incentivized equipment in the

[110] Some Midstream programs might have a budget cap and cease providing incentives part way through a given year once that budget cap is reached. Respondents should be prompted to think of their sales just during the period when the program was providing incentives when answering the Counterfactual question.

last year?

- In what percent of cases do you currently recommend program-incentivized equipment to your customers?
- In what percent of cases would you recommend program-incentivized equipment if the program were not available?
- What were the most important drivers that led you to upsell program-incentivized equipment over the last year?

6 Appendix A: Overview of NTG Methods

The evaluation teams present information in this appendix to provide a relatively quick overview of NTG methods for readers unaccustomed to the possible methods that evaluators may deploy. It is not meant to be a complete or deep discussion about each of the methods presented. However, the evaluators in Illinois considered the inclusion of this appendix to be very important in acknowledging the current suite of methods deployed by evaluators throughout the U.S. and giving a framework for work within Illinois.

Much of the information shown below is taken directly from a single source—the national Uniform Methods Project, Chapter 23: Estimating Net Savings: Common Practices. (Violette and Rathbun, 2014) This document has done a nice job of summarizing the eight most common attribution methods currently in use across the U.S. The evaluation teams recommend that readers go first to this reference for further information. Additionally, while there are slightly over 100 references within the Violette and Rathbun document, other non-duplicative references are included where reasonable as additional resources for those interested in further research into any specific method.

6.1 Survey-Based Approaches

Virtually all Illinois based evaluations use a survey-based approach for programs where primary data is used to determine net savings. (The main exception is for behavioral programs which use statistical analysis based on a randomized control trial program design.) Survey-based approaches obtain data from program participants and nonparticipants using a structured data collection instrument implemented via phone, in person, or online.[111] At times, evaluators create and use an unstructured depth-interview guide to collect information about attribution, and this provides both contextual data and quantitative data about a given project.

6.1.1 Self-Report Approach

The self-report approach relies on the abilities of customers to discuss the program influence as well as the somewhat abstract ideas of the counterfactual (i.e., what would have occurred absent the program) after making a choice to purchase an energy efficient item or take an energy efficient action unrelated to a purchase. For program participants, this could include doing nothing (i.e., leaving the existing equipment as-is), installing the same energy efficient equipment as they did through the program, or an intermediate step of installing equipment that is more efficient than what they had in place previously, but less efficient than what they installed through the program. Evaluators also use this approach when collecting information from trade allies or distributors. This self-report approach is not new, nor is it exclusively used by the energy efficiency industry. An important attribute of this approach is its reliance on well-designed and fielded survey questions; so that the data underlying subsequent analyses are accurate and complete.

The output of this approach is a NTG ratio which can be considered an index of the program's influence on the decision to install energy-efficient equipment. The NTG ratio is applied to gross savings in order to obtain an estimate of net savings. The NTG ratio may include free ridership, spillover, or market effects, depending on the survey and analytical design. NTG ratios may be calculated at the measure, suite of measures, or program level and are typically average values weighted by savings. If sufficient information is available, analysis of NTG ratios among certain customer segments may be done to further inform changes to program design.

References

- Sudman, 1996
- Stone, et al., 2000
- Bradburn, et al., 2004

[111] Historically, evaluators in Illinois have collected the majority of primary data via telephone surveys. As evaluations increasingly leverage online surveys to collect information relevant to attribution, careful attention should be paid to mode effects that are due to interviewer-administered versus self-administered surveys (e.g., scale direction effects). It is recommended that evaluators, where possible, assess the differences between telephone and online survey methods for the purposes of future updates to these protocols.

6.1.2 Econometric/Revealed Preference Approach

The econometric/revealed preference approach, while still considered a survey approach due to how data is collected, moves beyond asking people about the counterfactual and instead uses the observations of the evaluator to collect information for analysis of a NTG ratio. Within this approach, evaluators typically deploy similar sampling designs as for the self-report approach to collect data, but actively gather what a person is doing (i.e., what is being purchased in a store) to determine attribution.

6.2 NTG with Consumption Data Analysis

As mentioned in Section 0, evaluators use randomized control trials (RCTs), random encouragement designs (REDs), and quasi-experimental designs (QEDs) using consumption data (like monthly bills or AMI meter reads) to estimate savings for a variety of programs. RCTs estimate net savings by design but other consumption data analysis methods may be net, gross, or somewhere in between. In some cases, evaluators may be able to use methods that produce estimates that are acceptably close to net without further adjustment, while in other cases a NTGR may need to be developed outside the consumption data analysis and then multiplied by the estimate to produce net savings. Therefore, the NTG adjustment method will differ and needs to be justified by the evaluator on a case by case basis.

6.3 Deemed or Stipulated NTG Ratios

A deemed (or stipulated) NTG ratio is a value known prior to implementing a program and applied to estimate net savings for that program in a certain year.

Deemed or stipulated NTG ratios may be based on previous primary data collection, a review of secondary data, or agreed to among stakeholders. In Illinois, deemed or stipulated NTG ratios should reflect best estimates of likely future actual NTG ratios for the relevant program year, taking into consideration stakeholder input, the evaluator's expertise, and the best and most up-to-date information.

6.4 Common Practice Baseline Approaches

For this method, the evaluation team estimates what a typical consumer would have done at the time of the project implementation. Essentially, what is "commonly done" becomes the basis for baseline energy consumption and calculation of net savings. No gross impacts are calculated in this approach. This baseline is defined as the counterfactual "i.e., what would have occurred absent the program" and has been referred to as current practice, common practice, or industry standard practice. Evaluators determine these practices through multiple methods, but often can be from self-report or on-site audits. The difference between the energy use of measures installed in the program and the energy use associated with current practice is considered by some to be sufficiently close to the net savings.

This approach is not in use in Illinois, but it is used elsewhere in the country, such as the Pacific Northwest and Delaware.

6.5 Market Analyses

Market analyses can be done in several ways. Market analyses are often used in theory-driven evaluations of market transformation programs.

Other non-sales data market analyses can be postulated on changes specified in program logic such as: 1) changes in the number of energy-efficient units manufactured; 2) changes in market actor behavior around promotion or stocking of energy-efficient items; or 3) reductions in prices. The analyses involving non-sales data must make a clear link between the program intervention and the changes found in the market. Additionally, outside of Illinois, while evaluators have extrapolated the market changes to specific energy or demand reductions, this activity may be viewed as tenuous due to assumptions that evaluators must make within the analysis.

Illinois is in a position to begin to discuss market analyses and how specific research may be able to interpret changes that have occurred (or may occur in the future) because of the program interventions over the past eight years. Market analyses can be backward looking through historical tracing, but it is best used when the logic of an

intervention is described, and specific market metrics are tracked over time.

6.6 Structured Expert Judgment Approaches

Closely tied to market analysis, this approach is a way for evaluators to gather credible evidence of changes that arise due to the intervention of a program. When deployed, it is often used as a cost-effective approach to estimate market effects or reach agreement on a NTG value when several different types of evidence are available. The key premise of this approach is the use of a select group of known experts that all stakeholders agree can provide unbiased information as well as having sufficient knowledge to judge what may have occurred absent a program intervention.

A Delphi Panel is an example of this approach where data are collected from two or more rounds of data collection (which can occur via e-mail, Internet, or in person). A round is when experts make their thoughts known about a specific subject; the evaluation team synthesizes the data and provides this collated data back to the group to discuss again. Allowing the full experts to see how their peers think about a topic helps to move the group towards consensus.

6.7 Program Theory-Driven Approach

This approach is not included in the Violette and Rathbun (2017) document as a high-level method, but it is discussed by the authors under the historical tracing method. The Illinois evaluators believe that it deserves at least a short discussion within this framework.

A program theory is the written narrative about why the activities of a program are expected to bring about change. Typically associated with this approach is the direct graphical explication of the linkages between activities, outputs, and outcomes through an impact logic model.[112]

A theory-driven evaluation denotes "[A]ny evaluation strategy or approach that explicitly integrates and uses stakeholder, social science, some combination of, or other types of theories in conceptualizing, designing, conducting, interpreting, and applying an evaluation." (Coryn 2011) Within this approach, the ultimate conclusions regarding the efficacy of a program are based on the preponderance of the evidence and not on the results of any single analysis. Coryn and colleagues systematically examined 45 cases of theory-driven evaluations published over a 20-year period to ascertain how closely theory-driven evaluation practices comport with the key tenants of theory-driven evaluation as described and prescribed by prominent theoretical writers. One output from this analysis was the identification of the core principles and sub-principles of theory-driven evaluation. If interested, please review the reference under Coryn 2011.

As an approach, it is best used for complex programs and/or causal mechanisms that extend far into the future. Evaluators collect evidence that supports or rejects hypotheses that are explicit in the logic model. The case for program attribution is strengthened based on the extent to which an evaluation shows that the expected changes occur. Additionally, the evaluation team may be able to collect data that will answer questions about the longer-term outcomes of a program. This type of data collection may be very similar to market tracking activities described briefly above under Market Analyses.

This approach does not specifically estimate a NTG value, but Program Administrators can choose to keep, drop, or change a program based on intermediary data. Regulators must be convinced that the logic of a program is sound and that the intermediary outcomes are causally linked to expected savings.

[112] Evaluators may use logic models to show program processes as well, but this is a program flow chart, not an impact model.

6.8 Case Studies Design

Case studies are used extensively in social sciences as well as many other disciplines or practice-oriented areas, such as political science, economics, education, and public policy. Case studies help to understand the how and why of a situation and typically retain a holistic aspect of real-life events. As such, they may be a useful approach to determine attribution. As with program theory design, though, the data collected and analyzed within a case study approach will not typically yield a specific NTG value, but can provide credible evidence and insight that supports or refutes the changes brought about by program intervention.

To be used to assess attribution, evaluators must carefully design case studies to assure they account for the threats to causality (i.e., internal validity) that arise in any design. While not typically thought of in this manner, case study design can address multiple types of validity such as construct, internal, and external validity as well as assuring reliability. When establishing construct validity and reliability, evaluators must use multiple sources of evidence, create and maintain a study database, and maintain a "chain of evidence" within the analysis. Internal validity is shown through analytic tactics such as pattern matching, explanation building, addressing rival explanations, or using logic models. External validity centers on the ability to generalize the analytical findings to other similar situations. External validity may be shown through the replication of findings.

Attachment B: Effective Useful Life for Custom Measure Guidelines

The following guidelines should be used to determine the EUL values for custom measures and programs:

- The EUL values in TRM Section 3 and Section 4 are deemed. Attachment B **Error! Not a valid bookmark self-reference.** and Table 1-4 are a result of research into EUL values for custom measures and are also considered to be deemed.
- Identify the custom measure and consider if there are similar measures with EUL values already in TRM Section 3, Section 4, Table 1-3, or Table 1-4.
- Use the EUL for the similar measure or follow the guidance of Table 1-3 or Table 1-4 for Custom Other categories.

The evaluator will not change deemed values presented here for applicable custom measures and projects within the applicable program year of this TRM. The deemed values will apply to the verified lifetime savings and CPAS. As a result, the implementation team should be consistent and comprehensive in its documentation of the identified EUL if seeking a change for future years. Guidance for EUL research is offered following Table 1-4.

Table 1-3. Non-Residential Custom Measure End-Use Categories, Subcategories and Effective Useful Life Values

Program/End-Use Category	End-Use Subcategory	Sample Mapped Measures	EUL (years)	Notes
Combined Heat and Power	Combined Heat and Power	CHP	Capped at 25	Project specific
Compressed Air	Custom Compressed Air – Equipment	Compressed Air Pressure Reduction	15	Default value Future research may show that EULs for compressed air measures vary significantly between equipment and controls.
		Low-Pressure Blower System (replacing compressed air)		
	Custom Compressed Air – Controls	Compressed Air Flow Controller		
	Compressed Air Leak Repair	Compressed Air Leak Repair	1 - 5	A range of possible lifetime values is provided. Therefore, the implementers of this measure must justify the reason for selecting an appropriate measure life for each project and the decision will be subject to evaluation with the risk of adjustments.[113]
Data Centers	Custom Data Centers - Equipment	Data Center	15	Default values Future research may show that EULs for data center measures vary significantly between equipment and controls.
	Custom Data Centers – Controls		15	
Energy Management System	Energy Management System	Energy Management System	15	Default values

[113] Note during IL TRM v7.0 updates, this assumption was discussed at length with the realization that there is a lack of a strong source for defaulting the lifetime and different applications may vary significantly.

Program/End-Use Category	End-Use Subcategory	Sample Mapped Measures	EUL (years)	Notes
HVAC	Custom HVAC – Equipment	Custom Electric HVAC	13	Default values
		VAV Fume Hood		
	Custom HVAC - Controls	Chilled Water Reset	15	
		Fume Hood Occupancy Controls		
		Electric HVAC Controls		
		Low-Flow High Performance Hood -		
		Reduce/Optimize Air Change per Hour (ACH) Rate - Chiller		
		Sash Stops		
Lighting	New Construction/ Custom Lighting	Ceramic MH Lamp	15	Section 4.5.8 of the TRM covers 'Miscellaneous Commercial/Industrial Lighting'. It applies to "energy efficient lighting upgrades that are not captured in other measures within the TRM". The measure applies to retrofits and appears to be applicable to any non-prescriptive lighting measures, which would imply a 15-year measure life for custom lighting measures. It does not cover new construction or controls, thus the recommendation to include these subcategories.
		New Construction Lighting		
	Custom Lighting - Controls	Advanced Lighting Control Systems	10	
Non-Res New Construction	Non-Res New Construction	New Construction – Electric Measures	17.4	Based on research of measure level breakdown of typical projects in a program year.
		New Construction – Gas Measures	20.6	
Commercial Behavioral and Operations and Maintenance Programs	Commercial Behavioral and Operations and Maintenance Measures[114]	Remote HVAC or Lighting Control Changes	6	Based on Delphi panel analysis with consideration of ongoing engagement opportunities.
		Manual HVAC or Lighting Control Changes	2	
		Unknown (manual or remote)	4	

[114] These behavioral and O&M measures differ from other measure types in that a person must perform an action and this action must be checked periodically to ensure compliance. The savings of these measures depend on ongoing human interventions that may or may not continue to occur over time.

Program/End-Use Category	End-Use Subcategory	Sample Mapped Measures	EUL (years)	Notes
Refrigeration	Custom Refrigeration	Efficient Refrigeration Condenser Floating Head Pressure Controls Refrigerated Cases Refrigeration Compressor Refrigeration Controls	15	Default value Research may show that EULs for refrigeration measures vary significantly between equipment and controls. If that is not the case, the recommended end-use subcategory will continue working well. If that is the case, at that time the end-use subcategories should be updated to the following: Custom Refrigeration – Equipment Custom Refrigeration – Controls
Commissioning	Retro commissioning	RCx Measures	8.6	Research may show that EULs for RCx measures vary significantly between RCx categories or RCx delivery methods. If that is not the case, the recommended program level value will continue working well.

	Virtual Commissioning	Remote and Onsite Control Adjustments	7.3	Based on assuming that 70% of program activity is implemented via the building automation system and 30% are by other means:
				• RCx EUL of 8.6 years (weighted at 70% reflecting the BAS implemented measures)
				• Non-BAS implemented measures use a proxy averaging the following values to 4.3 years (weighted at 30%):
				  ○ SEM EUL of 5 years
				  ○ Remote changes of 6 years
				  ○ Manual changes of 2 years
				This weighted average calculates to an EUL of 7.3 years.

Strategic Energy Management	Strategic Energy Management	SEM	7	Only applicable to behavior or operational measures.

Program/End-Use Category	End-Use Subcategory	Sample Mapped Measures	EUL (years)	Notes
Business Energy Analyzer	Business Energy Analyzer	BEA	7.8	Based on Guidehouse survey on ComEd BEA users between December 15, 2022 and January 12, 2023 [115]
Custom	Custom – Gas	Process Furnace Replacement Process Dryer Process Heaters	Custom	Confirmed case-by-case, or use 25 years where available information is not definitive
		Grain Dryer	20	
		Dock Door Seals	7.5	
		Industrial Laundry Equipment	14 (barrier washer) 14 (washer extractor) 13 (pass-through tumble dryer) 13 (tumble dryer) 15 (cabinet dryer)	
		Cremators	18	
		Steam Generators	20	
		Boiler Blowdown Controls	25	
		Reverse Osmosis (RO) System	15	
		Barrel Wraps for Injection Molders and Extruders	Custom	This category is intended to capture unique, one-off projects/measures that do not fall under the other recommended end-use categories. Each project/measure should have a custom EUL. To achieve this, the implementer will provide an ex ante EUL for the project/measure and the evaluator will assess it for reasonableness and revise as necessary. As a last resort where there is no basis for a custom EUL a default of 13 years is provided and is deemed appropriate for electric measures, and a default of 17.4 years is provided and is deemed appropriate
		Blowers		
		Building Envelope		
		Controls		
		Cooling Tower/Heat Exchanger		
		Filter		

[115] Respondents were included in the sample if they logged onto the BEA portal at least once (not including their initial enrollment) in 2021 and 2022. This led to a final sample of 1,881 unique user accounts for the survey, with 151 completing the survey. Guidehouse reviewed the responses and estimated an EUL of 7.8 years for energy efficiency activity completed in 2021 and 2022, within the timeframe of using the BEA tool, outside of activity within existing ComEd programs. This weighted EUL of 7.8 years is based on the effective useful life of the measures implemented outside of other programs when the users also indicated influence in completing these measures from the BEA tool.

Program/End-Use Category	End-Use Subcategory	Sample Mapped Measures	EUL (years)	Notes
		Injection Molding Machine		for natural gas measures.
		Low Pressure Drop High Efficiency (Non-HEPA) Air Filters		
		Piping/Duct Modification		
		Pump/Fan Replacement		
		Vacuum System		

Table 1-4. Residential Custom Measure End-Use Categories, Subcategories and Effective Useful Life Values

Program/End-Use Category	End-Use Subcategory	Sample Mapped Measures	EUL (years)	Notes
HVAC	Thermostat Optimization	Thermostat Optimization	2	For up to two year's application of the optimization to the same customers. A third or more year applications would have a one year measure life until evidence of persistence is available.[116]
Res New Construction	Res New Construction	New Construction Electric Measures	18	
	Affordable Housing New Construction	Affordable Housing New Construction	-	Varies by project based on implemented measures

Guidance for EUL Research

The complexities of the various approaches for custom-like programs require a program-by-program perspective. The following process should be used when researching a new EUL value for custom measures. Similar to first year energy savings calculations, appropriate documentation should be provided to support the EUL value which may include references, approach, and reasons.

1. Identify the non-TRM measure and consider if there are similar measures with high quality EUL values already in the TRM. This initial step provides a benchmark for the EUL value.

[116] This limit to the two year measure life is due to the fact that the optimization builds upon itself; that is, if a thermostat is optimized during a cooling season the setpoints will remain at the optimized levels when that thermostat switches back into cooling mode in the following year, and further optimization applied in that year will change setpoints even further compared to the pre-optimization levels. As the setpoints get more and more extreme from repeated optimizations it is likely that the rate of manual adjustments to the setpoints goes up (thus overriding the optimized setpoints) which shortens the measure life.

2. Review the sources used to determine the EUL values for those similar measures. See **Error! Reference source not found.** and Table 1-4.
3. If the sources do not have EUL documentation for the non-TRM measure, research additional sources. The level of research effort should be commensurate with the savings potential for the non-TRM measure.
4. Submit the recommended EUL value and documentation for the non-TRM measure to the TRM Technical Advisory Committee for review through the annual TRM update process.

Source quality will be determined using hierarchy to describe the strength of the identified source as shown in **Error! Reference source not found.** below. In cases where a range of values are provided by a source versus an absolute EUL, the median value should be used. In other cases, if more than one high quality source is available with conflicting values, the one with primary research data with strong confidence in the findings should prevail, otherwise, the average EUL should be calculated.

	Source Name	Description
TYPE 1: Sources identified as highest strength: Primary research conducted or vetted by third-party entities such as trade organizations, national labs, or government organizations		
1.1	U.S. Department of Energy Federal Energy Conservation Standards	The U.S. Department of Energy (DOE) produces Technical Support Documents (TSD) detailing the analysis behind the federal conservation standards established for each product it regulates. Each TSD contains a chapter, often titled "Life Cycle Cost and Payback Period Analysis", that offers DOE's EUL estimate for the product and explains how this value was derived. Although the method depends on the data available for a given product, DOE's analysis generally relies on some combination of primary research, secondary research, modeling, and/or input from industry experts. The TSDs are linked from DOE's rulemaking page for each product, https://energy.gov/eere/buildings/standards-and-test-procedures. The TSD measure life values are based on shipment data, secondary literature research and primary research which include discussions with industry experts. Navigant considers as high quality because of the stakeholder review process and due diligence required to create these documents. Only the best available sources are used to support the EUL values used in life-cycle cost analysis for DOE federal equipment standards.
1.2	LED lighting reports prepared by Navigant	Navigant has performed extensive market research on the state of LED lighting for the US. DOE Solid State Lighting Program most recently published in 2016. It includes typical lifetime operating hours for each lamp type by sector. https://energy.gov/sites/prod/files/2016/09/f33/energysavingsforecast16_2.pdf
1.3	Appliance Magazine	Appliance Magazine publishes an annual report on the market value, life expectancy, and expected unit replacements for a range of consumer appliances. The appliances listed in this report change from year to year, so older versions of the report may be referenced for products no longer listed. As noted in the report, these EUL estimates represent the expert judgment of magazine staff based on input obtained from many sources. Portrait of the U.S. Appliance Industry (2001-2009). U.S. Appliance Industry: Market Share, Life Expectancy and & Replacement Market, and Saturation Levels (2010). U.S. Appliance Industry: Market Value, Life Expectancy and Replacement Picture (2011-2014).

	Source Name	Description
1.4	C&I Measure Life and Persistence Project	In 2011, Northeast Energy Efficiency Partnership sponsored this study of EUL of commercial and industrial lighting. The primary objective of this study was to conduct primary and secondary research and analysis for estimates of measure lifetimes that included on-site verification of CFL bulbs and fixtures, LED exit signs, HID fixtures, and T8 fixtures. Installations occurred from 1999-2009. http://www.neep.org/sites/default/files/resources/NEEP_CI_Persistence_Report-FINAL.pdf
TYPE 2: Sources identified as medium-high strength: Meta-analyses conducted by third-party organizations, that show some level of evaluating the studies that comprise the dataset		
2.1	California DEER	The most recent and comprehensive DEER documentation of EUL sources was from 2008 and 2014. The 2008 version identifies all the sources reviewed and justification for selected measure life. The 2014 measure list identifies the source used for the measure life. Many of the original references are from 2005, http://deeresources.com/files/deer2005/downloads/DEER2005UpdateFinalReport_ItronVersion.pdf, p. 11-1.
2.2	Regional Technical Forum (RTF) reference workbook	Ongoing revisions as measures undergo review. Similar to the 2008 DEER, the RTF identifies all the sources reviewed and justification for selected measure life.
2.3	GDS Reports	GDS Measure Life Report Residential and Commercial/Industrial Lighting and HVAC Measures – 2007. This study used various data sources such as DEER, state TRMs, and evaluation studies with a working group to review and decide on each value.
2.4	Focus on Energy Report	Focus on Energy Evaluation Business Programs: Measure Life Study Final Report: August 25, 2009 – this is a critical review of studies, workpapers and technical guides including a review of the underlying sources or supporting research.
2.5	ASHRAE	Original source is from Akalin, M.T. 1978. Equipment life and maintenance cost survey (RP-186). ASHRAE Transactions 84(2):94-106; Recent work is ASHRAE system life database (research project 1237-TRP) - which is a crowd-sourced approach to collecting actual system data. https://xp20.ashrae.org/publicdatabase/system_service_life.asp?selected_system_type=7
TYPE 3: Sources identified as medium strength: Compilations conducted by third-party organizations. Original sources should be cited, and locatable where applicable		
3.1	State TRMs	Many state TRMs reference each other and other sources of varying strength. Due diligence on reference documentation is not always present for the measure life. Many TRMs are reviewed via a stakeholder process.
3.2	ENERGY STAR calculators prepared by U.S. EPA and DOE (depending on the references used)	EPA's Energy Star offers calculators to help consumers and businesses estimate the energy and cost savings that could be realized by choosing to buy Energy Star certified products. Within these calculators, Energy Star offers a typical EUL and cites the source. Energy Star generally cites a single high-quality source (e.g., DOE, Appliance Magazine) for each EUL value and offers no analysis or discussion of the selected value. Energy Star's calculators can be accessed at www.energystar.gov. For example, their appliance calculator is available at www.energystar.gov/sites/default/files/asset/document/appliance_calculator.xlsx.

	Source Name	Description
TYPE 4: Sources identified as medium-low strength:		
Primary research conducted by interested parties such as manufacturers, distributors, retailers or installers		
4.1	Interview with interested parties (with no statistical rigor or analysis)	Manufacturer, distributor, installer, etc. have a vested interest and may overstate the benefit.
TYPE 5: Sources identified as low strength:		
Source where the basis of measure life is anecdotal, based on design specs, warranty period, etc.		
5.1	Industry blogs, Implementer or evaluator experience	Typically based on professional judgment and not rooted in any data.

Attachment C: Framework for Counting Market Transformation Savings in Illinois

1 Market Transformation Context

This Attachment was developed in 2019 within the Illinois Energy Efficiency Stakeholder Advisory Group (SAG) Market Transformation Savings Working Group, to describe a high-level framework for estimating savings from Market Transformation (MT) initiatives. MT protocols will need to be developed for individual MT initiatives as they are launched and may be documented in the IL-TRM or by posting agreed-upon protocols to the SAG website. The development and future inclusion of MT initiative-specific protocols in the IL-TRM will (1) help to ensure consistent evaluation approaches are used for similar MT initiatives that are offered throughout the state and (2) provide utilities with greater certainty as to how specific MT initiatives will be evaluated.

This Attachment is divided into two sections. The first gives the context of Market Transformation and describes some of its unique features that influence the estimation of savings. The second describes high-level methodologies for determining savings from MT initiatives.

1.1 Market Transformation Definition

This attachment uses the following definition for Market Transformation which is also used by the Midwest Market Transformation Collaborative and is very similar to definitions used by other organizations:

> *Market Transformation is the strategic process of intervening in a market to create lasting change that results in the accelerated adoption of energy efficient products, services and practices.*

1.2 Market Transformation and Resource Acquisition

An MT initiative (MTI) can include intervention activities similar to those seen in standard Resource Acquisition[117] (RA) programs, such as incentives that reduce first costs, training for trade allies, and marketing and case study materials[118]. However, MT initiatives additionally include activities that specifically seek to affect the long-term structure of a market in ways that are not easily undone; for example, working directly with manufacturers on product specifications and features or engaging with ENERGY STAR and DOE on test procedures and rulemakings.

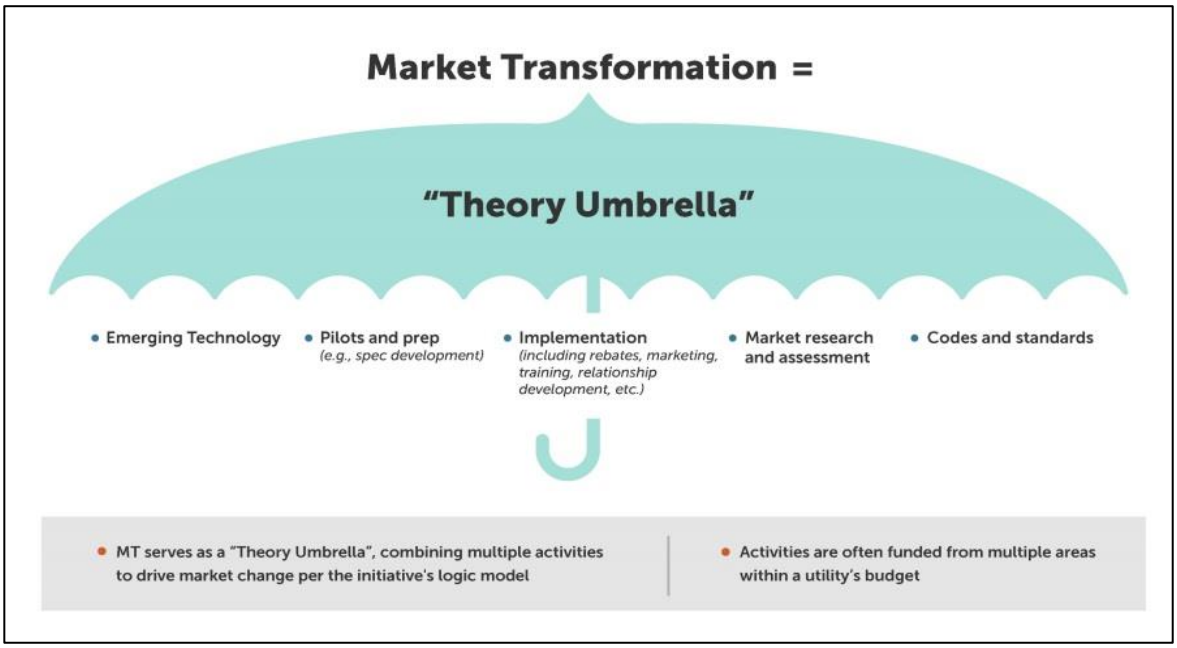
Figure 1 depicts the types of activities that might be included in an MT initiative. There are a number of other potential actions, such as discussions with stakeholders and setting up an evaluation plan, but that is not the subject of the figure. An example of an MTI with multiple interventions is the Heat Pump Water Heater (HPWH) Initiative[119] in the Northwest. Interventions include: technical support for development of ENERGY STAR specifications; laboratory testing of new HPWH to prove performance claims; upstream manufacturer engagement including incentives to encourage aggressive market pricing; customer facing retail rebates; providing technical information to the US DOE standards process in support of HPWHs being cost-effective for large tank sizes; and working with local jurisdictions to develop code provisions that provide “extra-credit” for HPWH in new construction.

[117] Resource acquisition is defined in the glossary but is used loosely in this Attachment to refer to more traditional utility driven energy efficiency programs that typically work at the individual consumer level, rather than the market level.

[118] For a review of best practices for designing and implementing market transformation initiatives, see Keating (2014).

[119] A description of this initiative can be found in recent reports from NEEA: https://neea.org/resources/northwest-heat-pump-water-heater-initiative-market-progress-evaluation-report-3 or https://neea.org/resources/northwest-heat-pump-water-heater-initiative-market-progress-evaluation-report-4

Figure 1. Examples of Potential MT Activities Under a "Theory Umbrella"



Each MT initiative must establish its own unique overarching MT theory with an "umbrella hypothesis" under which a variety of strategic activities, including those that may occur through other parts of the utility or even other organizations, can be combined to affect the desired market change. The goal of this set of activities is to reduce market barriers and leverage opportunities to create lasting market change. The entire set of activities is incorporated in the overall MT initiative hypothesis and logic model, even if some of those activities might be funded or implemented from different budgets or organizations.

RA activities can also result in market changes,[120] and RA savings approaches may also include documenting market effects for those programs independently from an MT initiative. However, RA savings are normally measured through participation in a program rather than whole market effects. There are further differences between RA and MT that influence the methods for calculating savings; key differences are shown in Table 1 below. Accounting for overlap in MT and RA program savings is discussed in a later section of this attachment.

Although an MT initiative might include activities similar to those employed in an RA program under the MT Theory Umbrella, the significant differences between MT and RA program types provide important context for planning, implementation and evaluation. As summarized in Table 1 below, these differences include: the scale of the intervention, the target market, the ultimate goal, the fundamental program approach, the time frame over which cost effectiveness must be evaluated, the amount of program administrator (PA) control, and the set of activities that are tracked, measured and evaluated.

Table 1. Comparing Resource Acquisition Programs and Market Transformation Initiatives[121]

	Resource Acquisition	Market Transformation
Scale	Program Administrator's service territory	Entire defined market

[120] For example, NMR Group, Inc. (2014) reviews methods for the evaluation of market effects primarily (though not exclusively) for RA programs.

[121] Source: adapted from Prahl and Keating, 2014; derived in turn from Keating, et al. and Sebold et al., 2001.

	Resource Acquisition	Market Transformation
Target	Whoever can be induced to participate	All consumers of a particular product or service
Goal	Near-term savings	Structural changes in the market leading to long term savings
Approach	Save energy through customer participation	Save energy through mobilizing the market
Scope of Effort	Results from a single program	May result from effects of multiple programs or interventions
Level of Program Administrator Control	PAs can control the pace, scale, geographic location, and can usually identify participants	Markets are very dynamic, and the PAs are only one set of actors. If, how, where, and when the impacts occur are usually beyond the direct control of the program administrators
Evaluation and Measurement	Energy use and savings, participants, free-ridership, and sometimes spillover	Interim and long-term indicators of market progress and structural changes, attribution to the program, and cumulative energy impacts
Timeframe for planning, savings measurement, and cost-effectiveness	Typically based on annual or multi-year planning and reporting cycle savings	Typically planned and implemented over a 10-20 year timeframe

Historically, the differences between the two approaches have resulted in challenges for MT initiatives to thrive in states where policy frameworks are strongly focused on resource acquisition.[122] The much longer time frame for MT initiatives and the lesser degree of program administrator control can be difficult to reconcile with policy rules that are focused largely on the precise quantification of annual savings.[123] Evaluation of savings can be fraught in jurisdictions where financial incentives or penalties are determined based on evaluated results, and can be particularly challenging for MT initiatives, which require market analyses that introduce additional uncertainty. Operating MT initiatives under these conditions requires upfront negotiation on evaluation processes to set clear expectations on measurement approaches.

1.3 Market Transformation and Attribution

The concept of attribution - or the attempt to assess the extent to which observed outcomes are caused by the program(s) of interest as opposed to events that would have happened regardless of any intervention - is fundamental to the evaluation of energy efficiency programs[124]. Without attribution, it is difficult to understand the success or failure of a program – or to improve (or to justify continued public funding for) a program whose success or failure is not understood.

[122] Note, for example that a regulatory framework supporting the MT initiative is cited as one of three "must-have components" for MT to thrive in a recent Illinois Summit on MT. ComEd Energy Efficiency Program "Energy Efficiency Market Transformation Summit Report", Navigant Consulting, February 2019.

[123] For a comprehensive discussion of the challenges of reconciling MT and RA within an RA-dominant policy framework, see Prahl and Keating (2014).

[124] See additional discussion on attribution in the Illinois Technical Reference Manual, Volume 4: Cross-Cutting Measures and Attachments, Section 2.

While attribution is relevant to both market transformation initiatives and resource acquisition programs, there are important differences to approaching attribution between the two types of programs. For resource acquisition programs, it has long been the norm in much of the US to treat attribution as a continuous variable that can be quantitatively scored (often in the form of a net-to-gross ratio that adjusts for free ridership and spillover) and applied to savings claims at frequent intervals with relative granularity. RA programs can ask questions directly of actual participants to ascertain attribution. However, MT initiatives typically do not lend themselves to this type of quantitative approach. More often than not, there is too much elapsed time over the lifecycle of a MTI and too many other market forces at work for a strictly quantitative attribution score to be meaningful on an annual basis. Instead, market transformation also requires qualitative judgements as to whether the initiative was generally successful in causing the intended market changes over extended periods of time.[125]

Successful incorporation of MT initiatives into a program portfolio that is dominated by resource acquisition programs generally requires that stakeholders accept these methodological differences between the two program approaches.

It is important to note this does not imply that quantitative estimates of savings should not be made for MT initiatives; fundamentally, all Illinois efficiency programs will need to quantitatively estimate saving, as long adopted policy requires counting the savings toward goals and estimating program cost-effectiveness. It simply means that savings for MT initiatives will be significantly less certain by nature than those for pure RA programs. Defensible methods for dealing with the limits to quantifying attribution for MT initiatives are discussed at length later in this attachment.

1.4 What Makes an MT Initiative Recognizable?

Because of the difference in evaluation approaches between an MT initiative and an RA program, it is important to first confirm whether an initiative falls into the MT category or the RA category before developing savings estimates.

To qualify as an MT initiative, there needs to be a clearly delineated target market,[126] as well as a documented theory of change in this market (or MT hypothesis) that is embedded in a defensible logic model.[127] This logic model provides the linkages between program activities and the anticipated lasting market change that accelerates the adoption of energy efficiency. The logic model is documented in the MT Business Plan[128] or similar document and is developed in advance of executing market interventions. MT initiatives are not created by looking backward and claiming credit for market changes from previous programs. Nor are all "upstream" programs MT by default. For example, an upstream program may not be designed to affect lasting change to the market; instead, the market would revert to its prior condition once the program incentive is removed.

2 Market Transformation Energy Savings and Evaluation

Energy savings from MT initiatives are the end result of increased and accelerated market adoption over and above a hypothesized future that would have happened without the MT initiative. Attributing savings to MT initiatives requires the assumption that some portion of the observed changes in market adoption are the direct result of a targeted, strategic market intervention that was designed and implemented to achieve that result. The MT framework requires both validation of the MT initiative logic and an evaluation of program implementation and progress towards specific market progress indicators (MPIs) before savings can be estimated.

[125] In this regard, the evaluation of market transformation initiatives closely resembles most other fields of social program evaluation, and it is actually the evaluation of resource acquisition programs that is unusual. For example, evaluations of early intervention education programs such as Head Start routinely concern themselves with the issue of attribution, but they generally do not seek to construct a quantitative attribution score for a specific program, region, and year.

[126] As shown in the glossary, this paper uses the following common definition of a market: an actual or nominal place where forces of demand and supply operate, and where buyers and sellers interact (directly or through intermediaries) to trade goods, services, or contracts or instruments, for money or barter.

[127] In some regions of the country, this is called a "program theory."

[128] The content of an MT Business Plan is listed in Appendix A.

The following section discusses several core concepts specific to the evaluation of MT initiatives.[129]

2.1 Theory-based Evaluation

Methodologically, MT evaluation tends to rely heavily on Theory-Based Evaluation (TBE).[130] TBE starts with a theory of change that explains how an intervention is expected to produce results. Because the subject of evaluation is an entire defined market rather than a program and its readily identifiable participants, MT evaluations tend to require numerous pieces of evidence that 1) change is occurring; and 2) the program is influential in causing that change.[131] This theory of change is embodied in the logic model that is the core of an MT initiative. A logic model provides the relationships and connections between program activities and anticipated changes in the market over the short, medium, and long term.

Evidence of a program's influence on its target market is gathered through an assessment of Market Progress Indicators designed to judge whether the program is achieving its intended outcomes. MPIs are market-based milestones associated with progress hypothesized in the logic model and confirmed as appropriate real-world indicators of progress. Examples of MPIs include market share of an efficient product option, changes in product availability, or evidence of promotional activity by affiliated or unaffiliated market actors. It is important to have a mix of leading indicators which provide timely feedback on the near-term progress of the program and the market (such as early shifts in market share), as well as lagging indicators which can be used to help assess longer-term outcomes (such as new entrants in the supply chain for the energy-efficient product). Regular assessment of MPI progress plays a central role in building a qualitative case for attribution over time via theory-based evaluation.

Assessment of MPIs will require incorporation of multiple judgements of progress based on a preponderance of evidence approach. It is important to note that "preponderance of evidence" does not require that all indicators show overwhelming evidence of programmatic influence, but rather that multiple indicators show consistent direction. This information can be qualitative (based on in-depth interviews or observational data collection) or quantitative (based on market share or production data). Evaluation plans for MT initiatives should propose evidence-gathering approaches to meet the "Preponderance of Evidence" standard.

Potential research needs and other evidence-gathering activities should be discussed and agreed upon by Program Administrators, Stakeholders, and Evaluators and documented in the MTI Evaluation Plan.

2.1.1 Market Progress Evaluation Reports

To evaluate a market transformation initiative effectively, it is essential to conduct regular research to understand market changes and implications for program adaptation. The Northwest Energy Efficiency Alliance (NEEA) refers to these regular evaluations as Market Progress Evaluation Reports (MPERs) and typically executes one per initiative yearly.[132] MPERs include components of impact and process evaluation, market research, and planning and market

[129] For a comprehensive review of best practices for the evaluation of market transformation initiatives, see NMR Group, Inc. (2013). For a more condensed discussion, see Prahl and Keating (2014). Metrics, Tracking, and Performance Assessment Working Group (2018) provides a regional perspective by discussing New York state's approach to the evaluation of its market transformation efforts. Also see Navigant (2018) for a discussion of bet practices in MT design. Finally, it is important to keep in mind that both market transformation initiatives and resource acquisition programs can cause market effects; NMR Group, Inc. (2014) reviews methods for the evaluation of market effects primarily (though not exclusively) for RA programs.

[130] See Chen (1990) or Weiss (1998). TBE is also often useful for resource acquisition programs but tends to be particularly central for the evaluation of market transformation initiatives. For a discussion of the application of TBE to energy efficiency programs in general, see Section 6.9 in Attachment A of the cross-cutting protocols.

[131] Examples might include: changes in efficient market share or product positioning; changes in leading indicators such as distributor stocking practices, consumer awareness, or new vendors entering into the market; self-reports of program effects from market actors; evidence of change in the prevalence of training/credentials, sales or installation data,—basically, evidence that the efficient option is being "normalized".

[132] In other regions, such recurring efforts may go by other names. However, the general concept of regular, recurring efforts to understand the progress of a market transformation initiative is widely accepted in the energy efficiency industry. This paper uses the term MPER for envisioned MT evaluations in Illinois. For examples of completed MPERs, see https://neea.org/resources-reports

assessments and are designed to document progress and market change over the initiative's life cycle. It usually takes multiple MPERs over time to tell the complete story of an initiative. The MPER scope is centered around 1) an assessment of the strength of remaining barriers and 2) measurement of Market Progress Indicators.[133]

2.2 Energy Savings Framework

Along with a program logic model, it is recommended that an Energy Savings Framework (ESF) be developed for every MT initiative. The ESF is the quantitative service-territory-level characterization of the market history and projections of the energy-efficient product or service, including 1) the expected energy and demand impact of the MT initiative and 2) the SAG-reviewed natural market baseline with defined utility attribution methodology. The ESF is a component of the MT Business Plan and reflects the impact of the MT initiative and program logic on the utility's portfolio. ESFs need to be developed for each MT initiative that doesn't already have one. For existing MTI's, the ESF should be evaluated each year to assess the need for an update, as described in section 2.3.

For each new MTI, sponsoring utilities and their implementation contractors, with input from evaluators, should submit an initial Energy Savings Framework to other Program Administrators, Commission Staff, and the SAG by September 1 of the ~~current~~ year prior to implementation. The ESF shall follow a consistent format that includes the requisite information. In early September, the utilities will present the rationale supporting the specific details for the ESF to the evaluator and other stakeholders and provide the SAG, in their advisory role, with an opportunity to review, question, and suggest modifications to the initial ESF. This process also applies to revisions to existing ESFs for in-process MTIs.

SAG participants shall make best efforts to reach consensus regarding new ESFs and revisions to existing ESFs. If the SAG reaches consensus regarding an appropriate ESF, or revision to an existing ESF, by October 1, then the SAG agreed-upon ESF shall be applied to the upcoming Program Year, even if it differs from the initial recommended ESF. If the SAG cannot reach consensus on an ESF, or revision to an existing ESF, prior to October 1, then the Evaluators' final recommended ESF shall be applied, which may be different from the initial proposed ESF[134]. In developing the final ESF, the Evaluator shall review SAG feedback, consider all comments and discussions, with the intent of making the best revisions to the ESF for the upcoming Program Year.

A "Comparison Exhibit of Non-Consensus TRM Update Issues" will be developed by the Evaluator with input from the parties and document the various parties' positions concerning a non-consensus. This Exhibit will be included with the Staff Report submitted to the Commission.

Gas utility annual energy savings goals will be adjusted for the entire Plan period, prior to the start of the first Plan Year of an approved Plan so that they are aligned with all current IL-TRM values, and the most recent SAG-agreed-upon (or Evaluator-recommended) MTI ESF.

2.2.1 Data Sources

In practice, planning a market transformation initiative requires developing a process for obtaining sufficient market data to enable the establishment of a reasonable baseline, as well as for on-going estimation of savings from the MT initiative. The ESF should identify these sources of information and how the data will be used. Below are a few of the approaches to meet this requirement:

[133] Market Progress Indicator is the term used in the Pacific Northwest. A closely related term that is often used in other regions of the country is "market indicator," although there are shades of differences in the meanings of the terms.

[134] SAG consensus is the desired outcome, but if consensus cannot be reached, the SAG will follow the same process outlined in sections 3.10 Consensus Decision-Making and 7.2 Net-to-Gross Policy, in the Illinois Energy Efficiency Policy Manual. https://www.ilsag.info/wp-content/uploads/IL_EE_Policy_Manual_Version_2.1_Final_12-7-2021-1.pdf

1. **Full category sales[135] or market practice data.**[136] Market analyses are most comprehensive when they include full category data from key actors in the supply chain, such as retailers or distributors. They can reveal unexpected trends in product categories that inform both trendlines and program interventions. These data make it possible to understand the market share of the efficient product relative to its competitive set.
2. **Primary data collection and extrapolation.** Because full category data is rarely available, primary research within the target market is frequently used to develop an understanding of the current level of market activity, including the portion consistent with the efficiency threshold sought by the program. Surveys with robust samples of trade allies, design professionals, and distributors can provide data on the square footage, sales in dollar value, project volume or denominator of interest. In cases where downstream rebate programs are operating in tandem with MT engagement, rebate processing data can provide a detailed look at a slice of the total market. Similarly, some upstream programs will be able to collect actual primary sales data on market share for some or all of the market.
3. **Secondary market data.** Regardless of the data available to the program, it is also best practice to include a scan for other sources of market data that might be available outside of the energy-efficiency community. Investment briefs, product trend analyses, JD Power or Consumer Reports data, and industry data often gathered by trade associations or similar organizations such as the Association of Home Appliance Manufacturers, NPD Group, Heating Air-conditioning Refrigeration Distributors International, etc. may provide important insights.

2.2.2 Factors in Estimating MT Savings

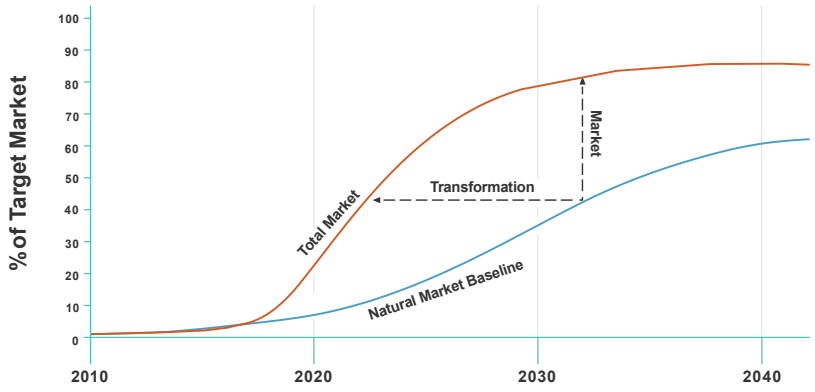
Three key factors must be considered when estimating MT savings. The first is the Total Market Savings that result from the entire market adoption of energy efficiency products or services. The second is the Natural Market Baseline, which is a forward-looking estimate of the market in the absence of any utility-funded energy efficiency activities. Figure 2 illustrates these two factors.[137]

[135] MT initiatives can also operate on buildings (like multi-family ordinances), engage corporations (like Strategic Energy Management), or even drive behavior change (like Building Operator Certification) – assuming they are structured as MT. The goal is still to gather total units as well as efficient units.

[136] Full category sales data includes all sales within a product category such as clothes washers -- both efficient and inefficient units.

[137] Not illustrated in the figure are further adjustments for savings from RA programs operating in the same market or allocations of the market savings to individual utility service territories. These are discussed in subsequent sections.

Figure 2. Framework for MT Savings



The third and final factor in estimating MT savings is the removal of savings specifically tied to RA programs operating in the same market to prevent double counting; this is described in Section 2.4. After all three factors are considered, then MT savings are typically allocated to individual service territories.

2.2.3 Estimating Total Market Units

Each market will have unique characteristics and data sources for tracking units. In many markets, extrapolations or approximations based on best available information will need to suffice. Ideally, the initiative should try to track both the total number of units in the market and the portion of units that meet the efficiency specification in the MT initiative (efficient units). Over time, Market Progress Evaluation Reports will describe shifts in the relationship between the numbers of efficient units and total units; the ratio of efficient units to total units represents the market share of efficient units.

In the case of gas-heated new home construction, for example, Market Progress Evaluation Reports would collect public information on new gas-heated housing starts and track the number of new homes meeting a particular efficiency specification. In mass markets, like appliances and commercial food service equipment, the best market data often resides with key market actors, like large distributors or manufacturers. In these cases, the design of the initiative should include a plan to secure sales data for the whole product category and the efficient units as an inherent part of the initiative's implementation. If not secured at the beginning of an initiative, this data can be difficult or impossible to secure later. As a result, it is optimal to design this data collection into the initiative when starting strategic partnerships with the market actors.

In many cases an initiative is unlikely to have participation from distributors, manufacturers and/or retailers that cover sales in 100% of the market. In this case factors need to be developed to extrapolate the data that is available for a portion of the market to the rest of the market.

2.2.4 Estimating Total Market Savings

Estimating total market savings requires the estimation of MT Units and Unit Energy Savings (UES). MT Units are the result of subtracting Natural Market Baseline Units from Total Market Units. The definition of "units" will depend on the energy-efficient product or service that is the focal point for the MT initiative. Units are defined upfront and typically are measured as: a device; square footage; number of housing units; number of operators; pound of product, etc. The appropriate unit definition will be identified in the MT Business Plan.

Savings are measured in kwh/unit, therms/unit, and kW/unit. Unit Energy Savings are defined as the difference between the unit energy consumption of the baseline product or service and that of the efficient one. This savings delta can be a deemed value already included in the TRM, calculated as part of the planning and baseline work that

informs typical MT programs, or directly tracked or researched. Note that the average savings per unit for a specific market likely will be the weighted average savings per unit for different categories of product (e.g., top-load or front-load clothes washer categories). For the purposes of this document, UES reflect the weighted average of all the categories included in the target market. MT UES is the result of subtracting the Unit Energy Consumption (UEC) of the efficient product/service from the UEC of the baseline product/service, as shown below.

MT Energy Savings = Number of MT Units (Units) x Unit Energy Savings (UES)

Where:

- *Number of MT Units = Number of Total Market Units – Number of Natural Market Baseline Units*
- *Unit Energy Savings = Unit Energy Consumption (UEC) of baseline product/service – UEC of EE product*

Note: Units are adjusted in a subsequent step to account for any overlap between RA and MT.

For MT programs that rely on shifts in practices or sales mixes, an appropriate approach to calculating savings may use the energy consumption embodied in the "standard practice" or "average sales mix," rather than a single widget-based calculation. When data are not available for the consumption of standard practice or average sales, modelling of an applicable energy code or standard can also be used.

Analysts can review and use existing sources of savings-per-unit information (or base- and efficient- consumption), if applicable. These sources could include TRMs; load forecasts; existing energy efficiency programs within the utility; emerging technology/R&D results; negotiated settlements on particular savings values, or other sources. Relevant information and associated data sources should be included in the ESF document.

If existing sources are not available or do not seem sufficiently reliable, the analyst should develop and implement a plan for securing more information on savings per unit. This may include product testing, piloting, or developing an agreed-upon proxy for use in the near term with a plan for developing more robust savings estimates over the longer term.

2.2.5 The Role of Natural Market Baseline and Attribution

The Natural Market Baseline (NMB) is a forecast of the future in which no utility-funded energy-efficiency programmatic intervention exists. Natural Market Baseline is removed from the Total Market Savings to ensure that the savings counted from ratepayer-funded activities do not include savings that would have occurred absent the utility-funded programs. This is the MT version of "attribution" and no further adjustment for free riders is needed.

As discussed earlier, attribution is typically in part established qualitatively for MT initiatives, yet under the policy framework in place in Illinois, a "net" savings figure must be determined. Subtracting the Natural Market Baseline from Total Market Units is the mechanism by which this is accomplished. Once an initial forecast has been made, the focus of evaluation efforts turns to building a case over time as to whether sufficient evidence exists to establish a link between program activities and market effects that are consistent with that forecast. As discussed below, depending on the body of evidence that emerges over time, the initial forecast for both Total Market Units and the Natural Market Baseline may be revised periodically (as described in Section 2.3). In addition, quantitative adjustments may be made to allocate total savings between sponsors or between MT and RA programs as discussed below.

In principle, subtracting the Natural Market Baseline from total market units yields by definition an estimate of total net savings[138]. Market influence and energy savings characterized in the Energy Savings Framework could be adjusted to account for market impacts due to non-Program causes in the following circumstances:

[138] This "net" savings includes savings from both MT and RA programs, so the "net" is further adjusted for RA savings, which is discussed in a section below.

- In the case where a utility joins an on-going Market Transformation initiative after the program is already underway and MPI evaluation shows progress prior to the utility joining, savings may be adjusted.
- A Market Transformation Program may target market actors willing to directly participate in the program. The program may indirectly influence the actions of similar market actors who do not participate in the program. Accounting for this indirect influence may result in partial or delayed market impact and savings.
- In the case where the ultimate goal of a Market Transformation Program is to influence the adoption of a new code or equipment standard, the program influence should be considered in the context of other independent influencers seeking the adoption of the same standard. In this case, an additional adjustment to the impact and savings may be applied to account for the attribution of influence on the standard adoption to others.

2.2.6 Natural Market Baseline Units[139]

2.2.6.1 Theory

The Natural Market Baseline should be modeled during the development of the MT initiative with the best available information, and then adjusted over time if significant new data becomes available during the implementation of the initiative, or because of unexpected market disruptions, such as those associated with substitute products.

Typically, the Natural Market Baseline will reflect at least some naturally occurring adoption of the targeted measure or practice because as Prahl and Keating (2014) note:

> With market transformation, the gross market changes observed over the time horizon of a market transformation initiative are not all linked to the utility or other public policy intervention. Some of it is naturally occurring – even a slow growing product, if it is moving into the market will have an increasing penetration, even without a strategic market transformation intervention. This equates to the non-net portion of resource acquisition. (pp. 45-46)

Forecasting Natural Market Baseline units often assumes that, over time, adoption of energy-efficient technology will follow a normal distribution consistent with Diffusion of Innovation theory. In this theory, market share is small due to a few innovators and early adopters participating in the market in early years, increasing to a majority of adopters during the peak years of market growth and then over time decreasing again to a small number of laggards adopting the product/service. Sometimes MT initiatives are primarily attempting to shift the adoption curve forward in time. Other times, they may be attempting to increase the slope and/or maximum values of the adoption curve

The Natural Market Baseline is probably the most challenging piece of estimating savings from MT because it is a prediction of the future that will never actually exist and therefore cannot be measured. As a result, it is important to involve evaluators and stakeholders in advance to ensure transparency, alignment and understanding of the data and judgement that will ultimately be used to estimate savings. All Market Transformation documents – The Program Plan & Logic Model, the Energy Savings Framework and the MT Program Evaluation Plan should be presented and discussed with Illinois stakeholders as early as possible.

2.2.6.2 Practice

The basic task is to develop a baseline of how the energy-efficient product, service or behavior would have grown in the market independent of utility activity. There are several elements for effectively developing the Natural Market Baseline:

1. **Identify existing data sources** that could inform the Natural Market Baseline and include these in the MT Business Plan. Market or sales data are the best sources, particularly if they are “full category” (or include the full efficiency mix, not just the qualified, efficient units). Other data sources can also be

[139] The term “Naturally Occurring Market Adoption” or NOMAD is synonymous with “Natural Market Baseline Units”.

used, including industry forecasts, market intelligence and trend information, primary data collected as part of market research or market characterization to support the initiative development, hedonic price modeling, or other information about how efficiency is positioned relative to other market drivers. In addition, trade associations, advisors to the target market/industry, investment grade forecasts or organizations related to regulatory oversight (like Lawrence Berkeley National Laboratory) can be good sources of data. Manufacturers or distributors themselves are excellent sources, but they may be unwilling to share proprietary information.

2. **Use available data, quantitative modeling, best judgement, proxy data or other techniques** to develop a Natural Market Baseline. Some projects lend themselves to modeling or model averaging using statistical approaches to estimating baseline sales behavior. These can incorporate different assumptions about how a program affects product sales. In many cases, multiple approaches can be used. For example, an evaluation completed for Consolidated Edison included a sales model, market share model, probit model[140] and a model averaging model, which were used in a single project to test different ways of estimating baseline sales.[141] In some cases, a comparison group (such as different but similar region that is not intervening in this market) may be used as a proxy.

3. **Develop the initial baseline curve** and have the shape of baseline curve and underlying assumptions reviewed by stakeholders. Several key product characteristics should be considered when determining the shape of the Natural Market Baseline curve. These characteristics include the maximum potential market share, the pace of innovation within a given market, the lifecycle or time between purchase decisions, the presence of non-energy benefits, and the incremental cost associated with the efficient product without the MT intervention. It is also important to consider the strength of identified barriers to adoption for a given product. These barriers often emerge from market research or market characterization studies and can point to installation or supply barriers that might otherwise be missed. In some cases, the Natural Market Baseline can be zero for a number of years. This might be the case when an MT initiative catalyzes the entrance into the market of a technology that otherwise would not have emerged for many more years.

4. **Incorporate anticipated changes to codes and standards** to the extent they are known in the baseline**.** The special case of savings from energy codes and standards is discussed further in the Energy Codes and Standards section of this protocol.

5. **Identify any known data gaps** that emerged in the planning process needed to improve the forecast over time and monitor these gaps as the initiative progresses.

Relevant information and their sources should be included in the Energy Savings Framework (ESF) document.

2.3 Reviewing Natural Market Baseline Over Time

It is important to track the baseline forecast periodically as part of MPERs or other recurring efforts to assess the progress of the program and the target market. Changes should be made to the Natural Market Baseline if a determination is made that new evidence suggests that the original forecast needs to be adjusted in order to accurately portray market behavior going forward, as discussed below.

Criteria for Updating the Natural Baseline Market Forecast

The fundamental reason for periodically reviewing the initial baseline forecast is because better information is likely to become available over time that may allow improvements in the accuracy of the initial forecast. The Natural Market Baseline forecast is a major determinant of the estimated savings attributable to the program. Given the challenges inherent in forecasting a counterfactual scenario, Natural Market Baseline often constitutes the biggest

[140] In statistics, a probit model is a type of regression where the dependent variable can take only two values, for example married or not married.

[141] EMI Consulting. Con Edison 2017 Retail Products Platform (RPP) Evaluation. June 15, 2018.

individual source of uncertainty surrounding estimated savings. As such, incorporating enhanced information regarding the Natural Market Baseline forecast helps both in building an improved qualitative case for attribution for observed market changes, and in supporting adaptive management of the program.

At the same time, it can be counterproductive and costly to update the baseline forecast too easily or too often. What is typically most readily available to the evaluator is the actual trajectory of total number of efficient units appearing in the market, which may well reflect effects from the MT program itself. This raises the risk that evaluators may decide that an observed acceleration in efficient market share is due to an acceleration in the Natural Market Baseline when it is actually due to the effects of the MT program, thereby leading to underestimation of the program's accomplishments – or the reverse can happen. Deciding how often to update the baseline forecast requires stakeholders to balance the desirability of incorporating valuable new information with the importance of ensuring reasonable treatment.[142]

Criteria for triggering an adjustment of the NMB should be agreed upon by program administrators and evaluators at the same time as development of the original baseline. At a minimum, each MT initiative's ESF should be re-assessed once per plan cycle regardless of the MTI's reopening criteria. Evaluators should examine all critical aspects of the ESF during this time including, but not limited to, the natural market baseline, unit energy savings, forecasted sales, market shares, and known codes and standards. Should the Evaluator determine a revision to an ESF is required, the existing ESF will apply to the funding utility for a maximum of two years, or until a new ESF is complete and adopted, whichever is shorter. As an example, if the 2023 program year evaluation triggers the need to revise the ESF, the utility will apply the existing ESF through 2025 at the longest, as the new ESF is drafted. Revisions to the ESF for a MT initiative apply prospectively to future program years.

The following are examples of some key `circumstances where it may be appropriate to update the initial Natural Market Baseline forecast:

1. **Key assumptions underlying the initial forecast have proven to be incorrect.** For example, the initial forecast may have reflected an assumption that in the absence of intervention, manufacturers would have little naturally-occurring incentive to incorporate a key energy-saving feature into their products, and it might become clear with the passage of time that this assumption was incorrect.
2. **The timing of key anticipated events has changed.** Examples might include a product launch being substantially delayed, a key partner ceasing operations, or an energy code or standard opportunity being delayed. All of these factors could affect the baseline forecast if it was built assuming certain events would impact the naturally occurring adoption.
3. **Changes in exogenous conditions affecting the target market have altered the initial trajectory of the Natural Market Baseline.** Examples might include a substantial change in public policy brought about by an electoral outcome, or economic conditions that create unexpected shifts in the level of economic activity (e.g. recession, housing booms, tariffs, unforeseen jump in the price of raw materials, etc.).
4. **Significant improvements in the availability of sales data demonstrate that the initial forecast can be improved without introducing a significant risk of over- or under-estimating program impacts.** For example, the initial forecast may have been based on limited information from key market informants, but over time full category sales data may become available and show that the initial estimate of efficient market share was off base.

[142] It is important to note that trying to strike this balance can and does lead to differences in baseline assumptions between MT initiatives and related RA programs. The mission of RA programs is generally to achieve measurable, reliable, near-term savings. From that perspective, it is important that the baseline assumptions reflect the realities at work in the marketplace at any one time. However, the mission of an MT initiative is to gradually achieve large-scale improvements in the way markets work, so it is important that the baseline forecast reflect the conditions facing the initiative at its onset. Resolving these potential differences in the handling of baseline assumptions between MT initiatives and related RA programs is an example of the broader issue of accounting, which is discussed elsewhere in this paper.

5. **The criteria for what constitute an "efficient" product have changed in a manner that tends to superannuate the initial baseline forecast.** Examples might include changes in test procedures or qualifying standards.
6. **Substitute products or innovations have been introduced that change the energy consumption profile of an entire product category.** Examples might include LEDs displacing CFLs, laptop computers overtaking desktops, and the addition of 4k or 8k features to televisions.

Stakeholders should recognize that Evaluators will likely need to conduct additional research to understand and incorporate the new market fundamentals. This will require budget resources and take time. The MT Program Evaluation should include a review of the on-going applicability of the ESF and recommend any additional research required to update the ESF. The specific recommendations and the basis for those changes should be presented to the SAG.

2.4 Accounting for RA Savings

Ideally, customer-facing RA programs would be an integrated part of MT activities. This would allow for counting all savings in the target market regardless of assignment to either MT or RA. However, in the near-term, RA programs are likely to continue to be implemented and evaluated separately from MT programs. As a result, if RA and MT programs are operating simultaneously in the same market, there is a need to parse the savings between the MT and RA efforts. This accounting is done within the Energy Savings Framework.

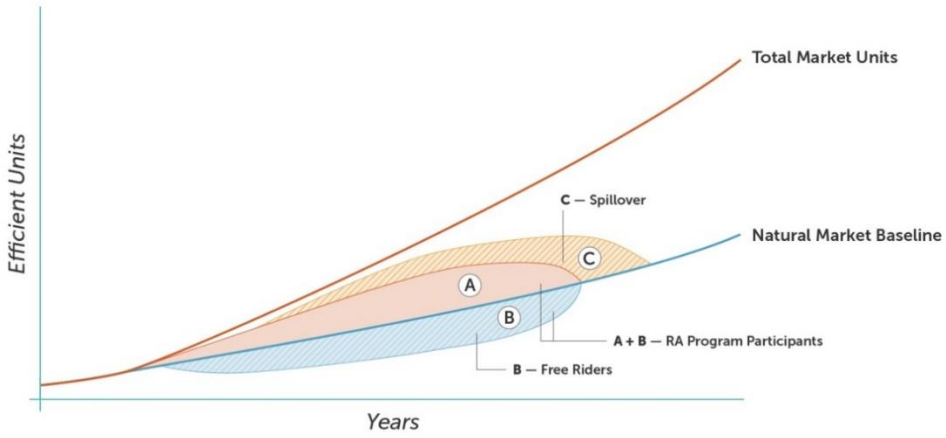
While the goal of not double counting is clear, the actual practice is complicated by the fact that RA and MT use different methodologies to get to a "net" savings. For example, both methodologies adjust for a counterfactual baseline; designated as free-ridership for RA programs and Natural Market Baseline for MT initiatives. Both methodologies also attempt to estimate market effects that occur beyond the direct program intervention; in an RA program, these effects are designated as spillover, while in an MT context they are accounted for in the NMB. To successfully avoid double counting of savings, the MT Energy Savings Framework must include consideration for all components of the RA framework.

Figure 3 is a depiction of the typical components of RA savings overlaid on the MT savings framework. Area A represents participants who wouldn't have taken the action without the program, area B is free riders and area C is spillover. As described above, MT savings are Total Market minus Natural Market Baseline.

To avoid double counting with RA programs, the default approach is to subtract all non-Market Transformation verified savings within the same market being targeted by the MT initiative from the MT savings calculated in previous sections[143]. If accuracy could be improved or greater cost-efficiency created in the evaluation process from using another method, that can be proposed by the evaluator. An example might be separating the units between the MT and RA activities but using the MT savings per unit (if it differs from the RA savings per unit) as the factor to multiply by the MT units.

[143] Note that the traditional use of the terms "net" and "gross" savings can be confusing in the MT framework. The MT savings calculation described in the first equation in Section II results in savings that are attributed to utility programs (both MT and RA) – typically called "net" in RA evaluation. This section then further nets out RA savings so MT savings can be separately analyzed.

Figure 3. Accounting for RA and MT Program Savings



A key benefit of netting out all RA claimed savings is that it allows for a straightforward assertion that "all savings counted through the RA program have been removed from the MT initiative savings". This simple statement may satisfy the needs of regulators and stakeholders without requiring further detail on the differences between the RA and MT frameworks.

On the other hand, this technique creates a bias against MT initiatives in favor of counting the savings in RA. This is because it has the unfortunate consequence of removing legitimate market effects (like spillover) from the MT initiative. This could discourage coordination and collaboration between MT initiatives and RA programs.

2.5 Allocating Energy Savings to Individual Utility Sponsors

Market boundaries rarely, if ever, align completely with the geographic boundaries of utility service territories. While it is possible for an individual utility to operate a market transformation program that is limited in scope to the boundaries of their own service territory, it is more likely that utilities will be implementing MT initiatives in collaboration with other entities at a state, regional, or even nationwide level. In multi-sponsored MT initiatives, an allocation scheme should be used to distribute savings to each sponsoring utility/efficiency organization. Historically, there have been several different approaches to utility allocation, although most of them attempt to base the proportion to each utility on estimated savings that land in that utility's service territory. The method used should be selected in advance.

1. **Allocation by Sponsor Funding Shares** In this approach, energy savings are allocated to each funder according to their share of the total MT initiative funding across all participating sponsors. In the Northwest, this approach is applied at a portfolio level to the total savings, partially because funding shares are based on the relative energy loads of the utilities.

2. **Allocation by Service Territory Delivery** This approach allocates energy savings based on an attempt to track market adoption of the energy efficient units (and therefore savings) to the geographic boundaries of the sponsoring utility. Unfortunately, most MT initiatives track efficient units at a scale different than utility service territory (such as to the point of distribution or retail sale), and methods must be used to scale these units to the service territory of the utilities operating the initiative. In these cases, a factor is developed in advance to share retail sales from the point of sale or distribution into an allocation to each of the utility service territories served by that channel. It is best to develop this factor ahead of time and use it consistently throughout the program, unless compelling data becomes available that would justify a change in the methodology. The adjustment can sometimes be made by working with the channel to get estimates of the zip codes of their clientele and then correlate that to the service territory zip codes. In the Northwest,

for example, Bonneville Power Administration developed a retail sales allocation tool where retail locations are divided up by how they serve customers from different utilities.

3. **Allocation by Tracking Participants** There may be initiatives where it is possible to track all participants – for example, Building Operator Certification where every tracked operator comes through the initiative itself. This can then be a direct measurement.
4. **Allocation by Survey of Market** This approach samples the entire market and asks survey questions about in which service territory the efficiency is occurring.
5. **Allocation by Customer Proportions or Energy Consumption** This approach allocates energy savings based on the share of total customers or energy consumption within the sponsoring utilities service territories, or if known, shares within a particular market. Customers or consumption in this approach are a proxy for relative market share for the MT initiative. Examples include total residential single-family homes with a certain type of appliance, number of industrial customers of a certain size, or total energy consumption of commercial end use loads for the market end use in question.

2.6 Estimating Savings Post Active-Market Engagement in Markets without Codes or Standards as an Endpoint

Not all MT initiatives have the possibility of a code or standard to lock-in sustained market change or will be successful in the achieving the desired code or standard. For example, programs seeking to change standard practice in operations and maintenance, influence recommendations for building upgrades in existing buildings (not typically affected by new construction codes) or create change via training often cannot rely on a code or standard to ensure sustained adoption. Even without a code or standard, it is still possible for estimated MT savings to become significant as the market adoption rate can grow exponentially. Therefore, it is important to design market evaluation components that support ongoing measurement and estimation of total market adoption and efficient units, even after MT investments have subsided. There may also be exogenous market factors that could trigger a reforecast of the Natural Market Baseline during this post period (see Section 2.3). A periodic independent evaluation of these elements is recommended to support continued and accurate calculation of successful, long-term MT savings.

Key considerations for post-active market engagement energy savings estimation include:

- **Total Market Units** Data collection for total market units may be more challenging if the market actors who previously provided full market data are not willing to continue doing so without an active value transaction. In some situations, access to sales data could continue via contractual agreements with key market actors. In many scenarios, however, analysts will need to infer market changes through surveys, adjustments to purchased third-party data, or on-going market studies.
- **Unit energy savings** Given the wider market adoption at this point; it may be necessary to adjust the unit energy savings estimate. For example, with wider adoption there may be better data about the actual energy savings performance of the efficient measure. Key assumptions that affect UES during this period may also change as a wider group of users engage with the product or service.
- **Natural Market Baseline** As adoption grows, often other market forces become more apparent and may warrant review and possible adjustment of the Natural Market Baseline. Also, exogenous variables can come into play in the market that simply could not have been foreseen during the initial forecast of the Natural Market Baseline.

2.6.1 Duration of Savings Post Active Market Engagement in Markets without Codes or Standards as an Endpoint

It is important to establish the length of time that savings will be credited to the utility post-active-market engagement. This time period is separate from the lifetime of the measures embodied in savings measures. Instead it reflects the amount of time that a utility will receive credit for having changed the market even when it has no or minimal engagement. In some circumstances, the Natural Market Baseline will be expected to increase over time

until some point where it essentially overtakes the Total Market. This provides a natural ending point for claiming savings from the MT initiative.

In some markets, the Natural Market Baseline will never approach the Total Market, or it will do so in an unreasonably long time frame. In these cases, there is no quantitative analysis to determine duration directly; instead, it requires a policy call that balances an appropriate level of credit to make it worth the effort to support MT initiatives without counting savings into perpetuity. Factors to consider in crafting this determination include the likelihood of the baseline changing over time and the lifecycle of the product (which influences when things would have changed anyway). The duration of energy savings should be addressed and captured in the Energy Savings Framework. Given that this is a policy call, it is usually best to make this decision early in the MT initiative design process to provide certainty to program designers and implementers.

2.7 Energy Codes and Appliance Standards

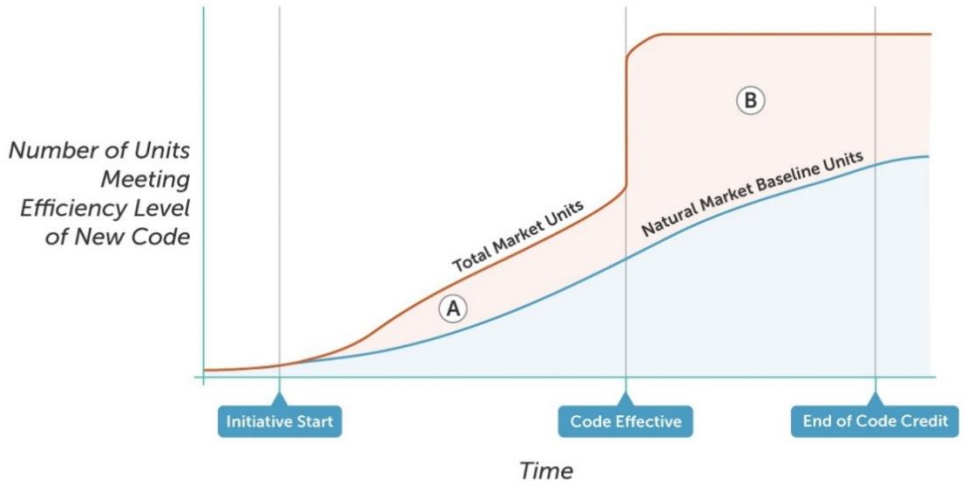
Best practice in MT initiative design will identify applicable codes or standards early on and design interventions over the life of the initiative to accelerate early adoption of more efficient energy codes and standards when possible. If an MT initiative can successfully influence the code or standard to incorporate higher levels of efficiency, the initiative can effectively "lock-in" sustained efficiency changes for virtually the entire market. Logic models for MT initiatives will often include activities that are deliberately targeting and driving towards adoption of enhanced energy codes or standards (C&S). Energy savings that occur following successful adoption of efficient C&S[144] are often a significant portion of the energy savings claimed. In California[145] and the Northwest, savings from C&S currently represent significant portions of the energy savings in their energy efficiency program portfolios.

Illinois does not yet count savings from energy codes or increased compliance, but as of this writing is discussing possible activities to influence energy code compliance and potential adoption of higher efficiency levels in energy codes and standards. This Attachment describes savings estimates from energy codes adoption[146] because these are often part of MT efforts[147] and energy code compliance enhancement activities because they increase the effectiveness of the codes.

Figure 4[148] depicts the course of an MT initiative with an emphasis on the portion that affects energy codes[149]. This figure shows a market where the natural market baseline does not have a regular code adoption cycle, but if that is the practice for the market being analyzed, anticipated energy code adoptions and their efficiency level would be included in the baseline. Area A represents the savings that accrue to activities in an MT initiative that prepare the market before C&S adoption and can include the wide variety of activities that are shown in Figure 1. Area B represents the savings following adoption of a new C&S. There are many activities that could be sponsored by utilities at the point of adopting a code or standard (just before the "code effective" vertical line). Some examples include developing model C&S language, providing technical and economic analysis and support, or submittal of C&S proposals.

[144] Energy code compliance is a key factor in the actual savings resulting from a code, and this is discussed in a later section.
[145] See TRC (2019) Codes & Standards Program Advocacy & Attribution study for a review of California's methods for codes and standards savings.
[146] Savings for "stretch" codes are covered by this discussion of codes and standards. If allowed by the state, a stretch code means local jurisdictions can adopt a code that is beyond the state code and is mandatory only for builders within that local jurisdiction. Savings would be calculated per this section, but only applied to buildings in the adopting jurisdiction.
[147] It should be noted that California has similar calculation methods for savings from codes and standards, although they weren't developed specifically under an MT framework. Massachusetts has developed a method for savings for code compliance that is similar to RA program analysis other than how attribution is estimated.
[148] Note that compliance with the energy code is usually less than -- and can sometimes be greater than 100%. Compliance greater than 100% can occur, for example, if the typical measure most readily available is more efficient than the code requirement; builders will simply use the available measure.
[149] In calculating savings, the effective date of the energy code or standard adoption drives the uptick in the number of efficient units meeting the efficiency level. In this paper, the term "adoption" is short-hand for the energy code or standard adoption, which would have an effective date by which most units will comply.

Figure 4. The Effect of Energy Code Adoption



If an MT initiative includes C&S activities as part of its logic model, energy savings from the pre-adoption period A in Figure 4 are counted using the methods described earlier. In addition, it can be credited with energy savings post-adoption B, which are also derived using the methods described earlier, but with some additional considerations, described below.

2.7.1 Additional Considerations for Savings from Codes and Standards[150]

This section describes the additional items needed to calculate savings from Codes and Standards (C&S). Per unit savings and total market units are calculated as described above. Additional factors that need consideration for C&S include:

- **Compliance rates when a new energy code is adopted:** Total Market Savings should be adjusted for measured or estimated compliance rates. Measured compliance pre- and post-adoption of the new energy code is strongly preferred, but not always available. In this case, a baseline compliance rate pre-adoption either measured or estimated is usually assumed to be the same post-adoption for purposes of energy savings estimation.
- **Post-adoption Natural Market Baseline:** Special attention should be given to the segment of the Natural Market Baseline (from energy code adoption to the end of energy code credit). The best representation of the counterfactual might be a fixed post-adoption baseline that changes to full adoption rates during the next scheduled change in the C&S processes (e.g. 3 years for the International Energy Conservation Code). Another option is some form of declining savings credit, such as a baseline that increases over time.
    - Determining the timing of this counter-factual movement in some alternate future has been difficult in those regions already counting savings from energy code adoption. One approach involves expert subject matter panels (Delphi panels) to establish this alternative future. However, finding enough independent experts and achieving convergence of opinion can be challenging. Trending market data or comparison with other similar code provision adoptions may also be used as alternatives. Ultimately, as with all counterfactual baseline estimation, there will need to be an aspect of professional judgement to determine the appropriate treatment of post-adoption baseline.

[150] A paper by Cadmus *et. al.* in 2013 describes the estimation of energy code adoption and energy code compliance savings in depth starting on page 52.

- **Accounting:** Accounting of savings between RA and MT programs is not generally used for C&S. This is because utility RA programs typically have ended operations before or at the point that the energy code adoption process takes place.
- **Allocation:** In principle, allocation of energy savings that occur from an MT initiative supported by multiple sponsoring utilities and targeting statewide code changes should be no different than during the voluntary portion of the MT initiative (see above section on allocation). In addition, there may need to be a split between utilities and other parties working on code adoption. This is often a negotiated number, sometimes informed by a Delphi panel, evaluators, stakeholders, or other entities.
- **Duration of Energy Savings Claims[151]:** It is important to establish the length of time that savings will be credited to the utility for the new code or standard. This is shown in Figure 4 as the time between "Code Effective" and "End of Code Credit". This time period is separate from the lifetime of the measures embodied in the energy code. Instead, it reflects the amount of time that a utility will receive credit for having changed the energy code.
    - There is no quantitative analysis that can determine the duration of an energy code credit to the utilities; instead, it requires a policy that provides an appropriate level of credit to implementers that makes it worth the effort to support MT initiatives that target code changes, while not being so large as to be unfair to ratepayers. The policy call can be informed by when the code or standard would have been updated anyway to the level targeted in the MT initiative. Given that this is a policy call, it is usually best to make this decision early in the MT initiative design process to provide certainty to the program designers and implementers. For example, the Northwest negotiated a standard policy that allows for claiming code savings for ten years post the code effective date. For the residential code, NEEA does not report savings units six months after the code becomes effective, and then counts savings for a full ten years. This was a negotiated number among the parties involved at the time. If a new, more efficient code comes into play during that period, the incremental savings for that change are also counted for ten years.

2.8 Energy Savings from Enhanced Energy Code Compliance Activities

From work in other regions, a number of activities, such as training and education, increased support for enforcement, and third-party plan-review have been shown to result in increased compliance of energy codes, which in turn results in energy savings[152]. Efforts are underway in Illinois to analyze and discuss activities for improving compliance with existing energy codes.

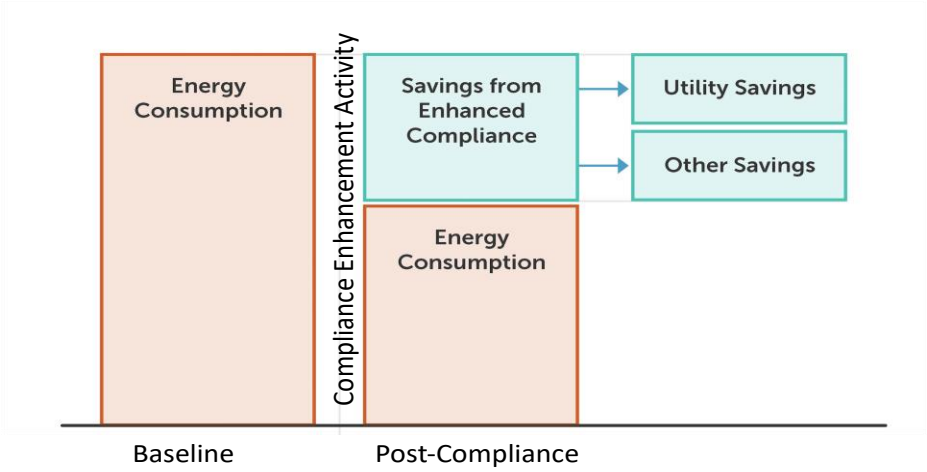
Savings from enhancing code compliance activities are derived by documenting compliance rates before the initiative starts[153], and compliance after the initiative has operated for a period of time. See Figure 5.

[151] Duration of savings claims can interact with the considerations in the Natural Market Baseline since this baseline can sometimes equate to Total Market Units over time, and therefore savings effectively become zero.

[152] For examples of recent evaluation reports analyzing the effects of compliance support programs on compliance rates in the residential and non-residential sectors, respectively, see NMR Group, Inc. (2018) and NMR Group, Inc. and Cadmus (2018):
NMR Group, Inc. 2018. Residential New Construction and CCSI Attribution Assessment (TXC48). http://ma-eeac.org/wordpress/wp-content/uploads/TXC_48_RNCAttribution_24AUG2018_Final.pdf
NMR Group, Inc. and Cadmus. 2018. Massachusetts TXC47 Non-Residential Code Compliance Support Initiative Attribution and Net Savings Assessment. http://ma-eeac.org/wordpress/wp-content/uploads/TXC_47_Nonres_CCSI_Attribution_Assessment_26July2018_Final-1.pdf.

[153] The Midwest Energy Efficiency Alliance is currently developing field data to determine compliance with current energy codes, and analyze which measures create the largest gap in savings.

Figure 5. Savings from Enhancing Energy Code Compliance



Unit energy savings[154] is the difference between the average unit energy consumption in the pre-enhanced-compliance case compared to the post-case[155] multiplied by the number of new units each year in the market that are affected. This is typically developed using building energy-use modeling of the baseline and post-compliance cases, and then subtracting the two. The building energy modeling should follow the practices for new construction modeling in the TRM for residential or commercial buildings as appropriate.

The per unit energy consumption for the baseline case is computed based on total building energy consumption with either measured or assumed compliance for all energy-impacting measures in the building. The per unit energy consumption for the post-compliance-enhancement activities is similarly calculated but using the energy-impacting measures of the post-compliance-enhancement building. For example, per building energy savings for wall insulation would be calculated by subtracting the building energy use assuming post-compliance-activity insulation amounts in the walls from an equivalent building energy use with the baseline wall insulation amounts. These building level savings are then divided by the square feet of the building to derive an average UES/square foot. This in turn is multiplied by the number of square feet in the market that are affected to derive the total compliance-enhancement related savings.

Total savings are then reviewed for the savings directly resulting from the efforts of the utility, versus other causes. Examples of other causes that can create enhanced code compliance include suppliers who might stock only "above code" materials or "spillover" from other larger jurisdictions that make it uneconomical for builders to change practices across jurisdictions. Most often, the split between utilities and other causes is a negotiated number among utilities and stakeholders which is sometimes informed by a Delphi panel that gives input to a third-party evaluator on their opinion of the utility's contribution if there are enough independent experts to form a Delphi panel.

2.8.1 Duration of Enhanced Energy Code Compliance Savings

Similar to the duration of savings credit for other MT initiatives, the actual value is a policy call. However, in the case of enhanced code compliance activities, duration of the activities is usually deemed to be the period of time that the particular code is in place. Once the code changes, (for example, every three years for the International Energy Conservation Code (IECC)), then credit for compliance-enhancement savings from the prior code would be stopped. This is because compliance savings are tied to a specific set of measures, and those measures may change when the

[154] In some cases, enhancing the compliance or effectiveness of measures in the code can have an impact on savings already incorporated in a TRM. If Illinois moves forward with enhanced code compliance, this could be an adjustment in the future to other sections of the TRM.

[155] If both compliance and increased efficiency happen at the same time, the savings can be calculated separately for each and summed.

code changes.

2.9 Uncertainty and Risk in MT Savings Estimates

MT interventions operate with a different level of certainty than many resource acquisition (RA) programs. Experimental design and tight error bounds on realized energy savings are not realistic expectations for initiatives that seek to animate, but not control, market shifts. One key reason for this greater uncertainty, as discussed above, is the greater difficulty of establishing attribution. In addition, needed market data (particularly sales data) can be hard to obtain. Finally, uncertainty also stems from items such as a rapidly changing product category or a reliance on the level of influence of retail salespeople.

To help utilities and other stakeholders assess the risks associated with this uncertainty, program designers should engage early with planning and evaluation professionals with experience in market transformation. Establishing energy savings methods associated with the proposed intervention and gaining acceptance for the proposed baseline often requires multiple rounds of review and refinement as data and assumptions are vetted. At the time of this writing, it is anticipated that the Illinois Stakeholder Advisory Group Working Group on Market Transformation Savings will serve as a forum to effectively plan MT initiatives and navigate unexpected market events.

2.10 Market Transformation Savings Protocol Process Recommendation

In 2022, the SAG Market Transformation Savings Working Group (SAG MT Savings Working Group) developed the Market Transformation Savings Protocol Process Recommendation which aims to:

- Formalize the MT process to streamline activities to reach consensus on MT Savings Protocols
- Define a set of recommended deliverables and work products that build to final MT Savings Protocols
- Provide recommendations on the order of operations for deliverables and work products
- Define a recommended set of activities and components
- Define a dashboard through which utilities can provide regular updates to SAG MT Savings Working Group participants

The Process Recommendation document is posted on the SAG MT Savings Working Group webpage: https://www.ilsag.info/mt_savings_working_group/

The processes outlined in this document are recommendations that provide guidance for actors working on MT initiatives in Illinois to help minimize the time necessary to reach consensus on MT Savings Protocols; the Process Recommendations document is not meant to be a formal checklist with requirements for each step. The Process Recommendations describes the foundational information and components of MT Savings Protocols that can be agreed on prior to utility implementation of a MT initiative. The specific process steps are likely to differ by MT initiative.

2.11 Market Transformation Program Design, Savings Protocol and Evaluation Plan Documentation

For Program Administrators, Stakeholders and Evaluators to be able to have an informed discussion and reach consensus on the anticipated savings for an MT Program, the Program Design (Logic Model) and ESF (the Market Characterization and Projection), along with supporting analyses, need to be documented. In addition, the MT Program Evaluation Plan should be developed and shared before a program is initiated. The Evaluation Plan will provide and explain the set of EM&V research tasks and how they will collectively meet the Preponderance of Evidence criteria explained in Section 2.1. These documents and the process for their development and review are summarized in Table 2.

Table 2. Summary of Market Transformation Program Supporting Documents

Document	Energy Savings Framework	Program Plan/Logic Model	Evaluation Plan
Summary of Document	*Market Characterization (Historical trends; market projection with NMB; unit sales & energy savings)*	*Program actions & intent; expected short-term and long-term outcomes; MPI's & measurement*	*Proposed evaluation research methods and plan – MPI's & ESF*
Document Developer	*Program Administrator (utility) with Implementation Contractor*	*Program Administrator (utility) with Implementation Contractor*	*Program Evaluator*
Review	*Program Evaluator (especially NMB); SAG*	*Program Evaluator; SAG*	*Program Administrator (utility) with Implementation Contractor; SAG*
Updating Process	*Evaluator assesses on-going adequacy of ESF; Change Recommendation reviewed by Program Administrator (utility) with Implementation Contractor and SAG*	*As needed by Program Administrator (utility) with Implementation Contractor with Recommendations by Evaluator*	*Updated annually by Evaluator; reviewed by Program Administrator (utility) and SAG*

3 Appendices

3.1 Appendix A: MT Initiative Business Plan Outline

The MT Initiative Business Plan is intended to document the strategy, data, and assumptions about the initiative at the time of launch. It is a document that can evolve as knowledge of the market and the initiative evolves but is essential to prepare and guide launch of the initiative into the market.

Key components of the Business Plan include:

1. Identification/description of the specific market to be targeted
2. Description of the "leverage" point(s) that catalyze transformation
3. Logic Model or hypothesis of how the planned intervention will result in the desired market change
    a. Barriers that prevent market adoption
    b. Activities/interventions that will catalyze the change
    c. Outputs that result from the activities
    d. Market Outcomes (short-, medium- and/or long-term) that are measurable responses to the activities
    e. Ultimate desired impact – which is the final state of the market after it is transformed.
4. Market Progress Indicators
    a. Data collection/management plan
    b. Document any input from evaluators
5. Multi-year budget
6. Multi-year savings, including description of baseline over time
7. Estimate of cost-effectiveness
8. Names of utilities most likely to be involved with operating this initiative
9. Description of interaction with other programs (if any) by utility

10. Description of Jobs or Disadvantaged Community Impacts
11. Discussion of risks specific to this initiative
12. Date of adoption and Date of amendment(s), if any

3.2 Appendix B: Glossary of Terms

Above Natural Market Baseline Savings Net of RA Savings – The residual estimated energy savings computed by subtraction of energy savings claimed by an RA program.

Accounting – For purposes of this document, accounting refers to the practice of adjusting MT above market baseline savings to net out energy savings being claimed through any RA programs operation in the same market.

Adoption Date (of Code or Standard) – The date when the change in a building code or appliance/equipment standard was adopted by the rule-making authority.

Allocation – The process of allocating energy savings from MT programs to multiple sponsors of an MT initiative that operates across multiple sponsoring utilities; e.g. at a state or multiple state regional level.

Attribution, general – The concept of attributing causality for claimed energy savings to specific or general actions by the utility(s) as opposed to other agents acting in the same market. Attribution provides credible evidence that there is a causal link between the program activities and the outcomes achieved by the program.

Attribution, MT Programs – Attribution of all energy savings not counted in the Natural Market Baseline to utility funded interventions, including RA, MT, and supporting infrastructure. Note that this is not actually a statement of causality but rather a measurement by subtraction of Natural Market Baseline.

Attribution, RA Programs – In traditional RA program attribution is generally approached through application of an adjustment factor that adjusts "gross energy savings" measured through the program participants to account for "free-ridership"; i.e., those participants that would have acted without the RA program. For RA programs, this adjustment is usually represented in a "net-to-gross" (NTG) factor that is multiplied by gross energy savings to get "net" energy savings that can be "attributable" to the RA program.

Counterfactual – A constructed alternative future that might have happened without the intervention of either the MT or RA programs.

Estimated Market Transformation Savings – The residual estimated energy savings computed by subtraction of the natural market baseline savings from total market savings. These estimated savings are assumed to be associated with all utility funded market interventions including MT and RA programs, supporting infrastructure, and codes and standards activities. Analogous to the space above the Natural Market Baseline in Figure 2.

Estimated Market Transformation Savings Net of RA – The residual estimated energy savings after subtracting energy savings claimed by a resource-acquisition (RA) program from Estimated Market Transformation energy savings operating in the same geographic service territory.

Free Riders – A program participant who would have implemented the program's measures or practices in the absence of the program. Free riders can be: (1) total, in which the participant's activity would have completely replicated the program measure; (2) partial, in which the participant's activity would have partially replicated the program measure; or (3) deferred, in which the participant's activity would have partially or completely replicated the program measure, but at a future time beyond the program's time frame.

Full Category Data – Sales data (individual SKU, price and numbers sold) for all units of a specific product including both efficient and inefficient versions typically sold through a retail or distributor channel. May also refer to data available from manufacturers or trade associations that includes all units manufactured or sold.

Hedonic Price Modelling – a statistical approach that controls for a variety of variables and attempts to isolate the incremental cost associated with the feature of interest.

Logic Model – a graphic depiction of the shared relationships among the activities, outputs, and outcomes of a program. The theory of change should be visible in the logic model.

Market – an actual or nominal place where forces of demand and supply operate, and where buyers and sellers interact (directly or through intermediaries) to trade goods, services or contracts or instruments, for money or barter.

Market Progress Evaluation Report (MPER) – A report on MT program progress, usually conducted in parallel with program implementation over a relatively short (e.g. 12 months) timeline. Best practices would have these evaluation activities conducted by a third party. [Note that there are regionally distinct terms for similar evaluation products, including Market Evaluation. The specific term is less important for the purpose of this framework than the need to acknowledge that market transformation requires a somewhat different evaluation scope and product than might be required of other programs.]

Market Progress Indicator (MPI) – A measurement of market progress for a specific indicator of an element of MT theory described in the program logic that defines the associate barrier/opportunity/intervention strategy and anticipated outcomes from successful implementation. [Note that regional differences exist in how these indicators are labeled, including the term Market Indicator. The specific term is less important than the fact that the indicator refers to activities occurring within the market, rather than within the program, and that they will likely include long-term indicators that can take years to emerge.]

Market Transformation (MT) – The strategic process of intervening in a market to create lasting change that results in the accelerated adoption of energy efficient products, services, and practices.

MT Business Plan - A document embodying the strategy, data, and assumptions about the MT initiative at the time of launch. It includes a description of the efficiency opportunity, targeted markets, assessment of barriers and opportunities, intervention strategies, near-, mid- and long-term market outcomes, market progress indicators and key energy savings estimation assumptions.

Natural Market Baseline Savings – The estimated energy savings computed based on a market adoption rate forecast of what would have happened without any utility funded interventions that may include both MT and RA programs as well as enabling infrastructure support. The forecast of Natural Market Baseline is generally established before the start of the MT initiative but may be revised periodically.

Resource Acquisition (RA) – An approach to capture energy efficiency grounded in a regulatory framework which views EE as a resource that can be "acquired" through direct utility action analogous to any other "resource" considered by a utility to meet its existing and future energy requirements. These can be thought of as traditional utility-driven energy efficiency programs that typically work at the individual consumer level, rather than the market level.

Spillover – Reductions in energy consumption and/or demand caused by the presence of an energy efficiency program. There can be participant and/or nonparticipant spillover:

- **Participant spillover** is the additional energy savings that occur as a result of the program's influence when a program participant independently installs incremental energy efficiency measures or applies energy-saving practices after having participated in the energy efficiency program.
- **Nonparticipant spillover** is energy savings that occur when a program nonparticipant installs energy efficiency measures or applies energy savings practices as a result of a program's influence.

Summative Report – An evaluation report that attempts to quantify and assess the outcome effects for a given program period. Distinguished from "process evaluation" and consistent with "impact evaluation" in energy efficiency.

Total Market Savings – The estimated energy savings computed based on all market adoption above and beyond the adoption rate at the start of the MT initiative.
